The treatment I adopted was, three daily doses of some form of arsenic—either the arsenite of potash or of soda; a little cod-liver oil; and sesquioxide of iron. As regarded diet, the only prohibition was fish and stimulants—neither of which she had habitually used. I directed her to drink largely of cold water or barley-water, etc., to promote the "metamorphosis of tissue". The details of treatment are superfluous. Very little of the cod-liver oil could be taken because of nausea. A recommended change of air was found impracticable; so that the treatment was very much narrowed to the ingestion of arsenic. It was only discontinued during two weeks from February 11th to December 31st. Improvement commenced about August, and steadily went on, till at Christmas the cure was complete. There was a little conjunctivitis occasionally, and at the end considerable anæmia and debility, now rapidly disappearing under the use of tincture of sesquichloride of iron.

On February 6th, 1865, she came here for my inspection. The only remains of her former enemy were slight stains on the cheeks, which showed when she was excited or hot. The whole surface of the body was clear, smooth, and healthy. She looked upon life as now something desirable, as she had entered on, as it were, a new phase of existence.

Post hoc, certainly; propter hoc, surely.

CAPTAIN GORDON, who has lately so distinguished himself as leader of a Chinese army against the Taepings was accompanied in his perilous enterprise by only one officer—a medical officer. The *Times* says: "Gordon accepted the very perilous offer. He went upon half-pay, thus risking his prospects of promotion, and taking a step in which only one officer—a medical officer—was found to follow him."

BEQUESTS. By will, Miss Rachel Lamage, of Stoke Newington, has left the following bequests: To the German Hospital, the Royal Free Hospital, London Fever Hospital, Middlesex Hospital, St. Thomas's Hospital, North London Hospital, Margate Sea-Bathing Infirmary, Hospital for Incurables, each £100; Charing Cross Hospital and Stoke Newington Dispensary, £50 each.—Miss Julia Olivia Brodie, of York Place, Portman Square, has left the following legacies: The Cripples' Home Refuge, Infant Nursery, and Laundry, Marylebone Road, £300; British Orphan Asylum, Slough, £300; Idiots' Home, Redhill, £200; Royal Westminster Ophthalmic Hospital, £200; Infirmary for Consumption, Margaret Street, £200; Samaritan Hospital for Women and Children, £200; Cancer Hospital, £100; Establishment for Invalid Gentlewomen, £200; Orthopædic Hospital, £50; Society for the Prevention of Cruelty to Animals, £50; St. George's Hospital, £100; Middlesex Hospital, £100; University College Hospital, £100; Guy's Hospital, £100; Hospital for Consumption, Brompton, £100.

We beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, MARCH 25TH, 1865.

MEDICAL EVIDENCE ON RAILWAY ACCIDENTS.

THERE appears to be something more in the results of many railway accidents, in which human beings are concerned, than is usually dreamt of in the philosophy of medicine. With many medical men, it would appear as if *de non existentibus et non apparentibus eadem est ratio*, in reference to certain of the phenomena which represent these accidents. They do not seem to believe in any of those morbid symptoms of which the patient tells, but of which they cannot themselves seize the physical demonstration. Of course, we are now speaking of those medical men who appear as witnesses in courts of law to defend railway companies against the pecuniary damages sought from them by their injured passengers. That the injured individual should endeavour to make the worst of his case against the company, is a matter of course; and therefore the company is quite right to defend itself against the attempts of extortion. Of this we do not complain; but we think—indeed, we are sure—that our profession greatly errs in lending its aid, as it so often does, in depreciating the amount of injury suffered by an individual. We do not believe that railway companies have gained much by the practice of calling witnesses to declare that the plaintiff is doing something like attempting to humbug them; and we are sure our profession has not gained much credit with the public by assisting the companies in the matter. That medical witnesses on behalf of the companies often give very unfair—we mean incorrect—evidence, is certain. We know more than one case in which it was asserted by certain very high medical authorities, that the plaintiff was, in their opinion, perfectly sound—as well as he was before the accident; or, in other words, that he was trying to extort money from the company. And we also know that in such a case, to this day—now three or four years after the accident—the patient has never perfectly recovered from the *shock*. A collection of certain of the consequences of these modern kind of accidents, with a true history of their results, would be a very valuable addition to our pathology. We mean the kind of accidents which present no external signs of

injury, but are represented to us solely by symptoms described, and capable of description only, by the sufferer himself—of injury to motion or sensation. A person receives a violent shock in a railway carriage. His loins, or head, or some other part of his body, are thrown violently against the carriage. He perhaps, at the moment, may suffer very slightly: but afterwards he will complain of weakness of the limbs, pain in the back or head, and confusion of his intellectual faculties; and yet present no marked symptoms of paralysis or disease of the nervous centres. Now, in such a case as this, it is manifest that the individual *must* be the exponent of his own symptoms. The signs which indicate injury of the nervous centres (of the kind supposed) are, from the very nature of the case, signs which can be represented to us only by the words of the patient himself. More than this: we know that all he says may be the truth; that the tale of his weakened powers of mind or body is perfectly consistent with well ascertained pathological facts. We know that men frequently never fully recover from the effects of certain violent shocks. They may look to all appearance perfectly in health, but yet they are not so; they are not the men they were before. If such individuals come to us as private patients, we believe implicitly what they tell us, because there is nothing in their statement contrary to what we know may be perfectly true. Why, then, should medical men go boldly into the witness-box in cases of this sort, and boldly aver that they believe there is nothing the matter with the man? The case mentioned below is not a case of this kind; but it exhibits a greater divergence of opinion than we like to see given by members of the profession. The nature of the accident from which the plaintiff suffered is thus described.

"At the time of the accident, the plaintiff was thrown violently against the back of the bench opposite to him; but he did not feel any injury at the time, and assisted Dr. Woodward in attending to the other wounded. On his way home, the plaintiff found his stockings to be wet with blood, and felt shiverings, and could not remember the names of the people who were with him. The plaintiff next day attempted to go to business, but was obliged to be taken home in a cab. He then became seriously ill, with intense pains in the head, deafness of one ear, and acute sensibility in the other. He suffered also from intolerance of light, and loud noises, like the hum of a thrashing-machine, in his head. He was recommended rest, and sent to a place about four miles from Worcester, and afterwards went to Malvern for about six weeks; but, instead of improving, he became worse. He was then attended by Dr. Hastings and Mr. Everett of Worcester. He was afterwards attacked with violent spasms in one hand and foot, and pains as of knives being thrust through his chest to his backbone. Mr. Carden of Worcester was then called in. No improvement has taken place; and, when the plaintiff came into the witness-box, he presented the appearance of a man suffering from intense pain. He stated that he was subject to horrible dreams, and had not had more than three

nights' rest since the accident. Mr. Erichsen, Dr. Hastings, Mr. Carden, and Mr. Everett gave it as their opinion that there was injury to the brain and spine at the point of junction between the brain and spinal cord, and that the plaintiff's ultimate recovery to his full vigour was very doubtful. For the defendants, Mr. Skey, Dr. Wade, Mr. Cooper, Mr. Bradon, and two other medical gentlemen, stated that the plaintiff's symptoms were consistent with and attributable to hysteria; but they admitted that it was possible that hysteria might supervene upon or be concurrent with the effects of the accident. The plaintiff had never suffered from hysteria. The plaintiff had been a most energetic man of business; and since the accident the business of the firm had greatly fallen off, the other partners being incapable of its management."

The jury, however, did not take in the hysterical hypothesis, and awarded to the plaintiff £6,000 damages.

ENDOSCOPY.

On Wednesday, the 15th instant, at a meeting of the Medical Society of the King and Queen's College of Physicians, held in the new College Hall, Kildare Street, Dr. F. R. Cruise, of the Mater Misericordiæ Hospital, exhibited an "endoscope" which he has been using for some time past, and read a short paper explaining its practical utility in the diagnosis and treatment of many obscure forms of disease, especially those of the rectum and urino-genital organs. Dr. Cruise's endoscope is a modification of Desormaux's, and possesses the great advantage over it of an illuminating apparatus, so brilliant, and easily admitting of such perfect adjustment, that little or no previous training is required to enable the practitioner to obtain a satisfactory view of deep cavities which heretofore have been generally looked upon as quite inaccessible to sight.

Amongst these, we may specially mention the bladder and urethra: the rectum beyond the reach of the finger and speculum: the cavity of the cervix, and even of the body of the uterus; the nasal fossæ; the pharynx; cavities of ovarian cysts; abscesses; wounds containing foreign bodies: etc.

Dr. Cruise's paper was enriched by the details of a number of obscure cases in which he had used the endoscope to the entire satisfaction of numerous medical men in Dublin.

This instrument, which has been thought of and talked about for the last thirty years, has from time to time attracted passing attention, and then sunk back into oblivion.

M. Segalas would appear to have originated the idea of endoscopy, which he soon abandoned as impracticable; and the late Mr. Avery of London paid much attention to it. Sir Philip Crampton also is said to have taken up the matter at one time; but no result followed. It would appear that of late years M. Desormaux of Paris has been the only

worker in this unexplored field; and to his perseverance much credit must be given.

This negligence would appear to be mainly due to the difficulty of obtaining a satisfactory and manageable illumination. Dr. Cruise has undoubtedly removed this difficulty; and now, for the first time in this country, the endoscope has been proved an unquestionable success, and likely before long to modify and correct our opinions respecting certain obscure ailments, and to serve materially in their treatment.

It is unnecessary to enter into details of the means by which Dr. Cruise obtains the admirable illumination and adjustment in his instrument, as we understand he is about very shortly to publish an account of it, as also a *résumé* of the work hitherto accomplished by its use. We think it only justice, however, to notice his labours and improvements, and the very favourable reception his communication met on Wednesday, and to give him the credit of priority in following up in this country the study of the long neglected endoscope, and demonstrating, for the first time in Dublin, its value as an aid in diagnosis and treatment.

SCIENTIFIC INQUIRIES.

It is to be hoped that the Medical and Chirurgical Society will continue the good work which it has commenced, of scientifically inquiring into matters physiological, therapeutical, etc. It is needless to say that there is a vast field still open for its researches; and we are sure that the Pathological Society will agree with us in this, that in no way could the funds of the old Society be better expended than in carrying out the kinds of investigation alluded to. Its next efforts, we may suggest, may well be turned towards the question of the action of our therapeutical agents. Such an inquiry would naturally involve clinical observations. And we would ask, Might not the occasion be indirectly turned to another most excellent purpose? How often is it that the hospital practice of a physician or surgeon is *controlled* or fairly judged of by competent authority? Now, might not the Medical and Chirurgical Society, to the advantage of science, appoint a committee to investigate personally, at the bedside of the patient, the real value of any particular treatment of disease which is highly extolled by the individual who employs it? It is often surprising to note the differences in practice, in matters of principle as well as detail, which are often to be met with even in neighbouring hospitals. Surely there would be a better chance of agreement being come to in matters of opinion and practice, if physicians and surgeons could only see the doings of their brethren, and judge for themselves. In the present

state of isolation, men naturally become overwedded to and wrapped up in their old routine of practice. And on this point we may observe, that it has always seemed to us just as great a misfortune that medical students have not an opportunity of seeing the different practice of physicians and surgeons at different hospitals, as it is that physicians and surgeons of one hospital themselves know so little of what is being done by their *confrères* in another hospital. A medical commission of inquiry, started under the authority of the Medical and Chirurgical Society, might perchance pave the way to a more general diffusion of the different practices which are followed in different hospitals, as well as tend to settle the real value of particular methods of treating diseases. At all events, let us hope that the Society has merely commenced its career of active scientific investigation; and that it will still show itself ready to continue its labours into any field of research worthy of its attention. Is there any question, we would suggest in conclusion, more worthy of attention, or one more likely to be productive of great practical results, than the question of hydrotherapeia—the cure of diseases by the agency of water, in all its different modes of application? One thing is very sure; viz., that the profession has allowed quackery to get possession of the remedy, for remedy it surely must be called; and also sure is it that there is not a hospital in London which is possessed of the means of applying the remedy in all its possible forms. Dr. Risdon Bennett and some few other hospital physicians have now and then resorted to and spoken highly of the use of the remedy in some of those forms of it which are usually regarded by the profession with a certain kind of suspicion—and solely, we suppose, because quackery has had the wit to forestall the profession in the general use of them. Here, then, is a grand occasion for science to come forward and maintain its right to the use of all things proved to be good and useful in the cure of diseases. Let the Medical and Chirurgical Society try and prove the value of water in the cure of diseases, and report thereon. The apathy of the profession on the subject is really very surprising. That the remedy is a powerful one is certain; and that it must be powerful for good or evil also certain. A scientific committee would enlighten us; and, if they decided that the remedy was a grand one, is it not certain that every hospital in this country would be under an obligation at once to add to its therapeutical remedies the means of applying the remedy—a complete bath establishment? But if Turkish baths, wet sheets, and all the other powerful means of acting on the human frame which are employed by quacks and unscientific people, and by the public, be really injurious, then is it our duty publicly to proclaim the fact.

ANOTHER victim to the scoundrels who disgrace our civilisation is recorded in last week's papers. It may be very difficult, perhaps impossible, for the law to touch them; but surely something might be done to purge the country of the filthy demonstrations of their existence which pollute so many of our newspapers, and even our public streets. The case, at all events, is one which might well occupy for a short time the consideration of our great medical discussion forum. Some suggestions the Medical Council might perchance make, which would tend to the diminution of the "vigour of life" infamy.

"SUICIDE OF A CORPORAL IN THE GUARDS. An inquiry was held at the Westminster Hospital, respecting the suicide of Corporal Ashford of the Coldstream Guards. Colonel Strong and many officers of the regiment were present. Mr. Myers, assistant-surgeon, said he found deceased lying quite dead, with his feet on the bed and his head on the floor; a discharged rifle lay underneath the body. The deceased had evidently leant out of bed, placed the muzzle of the rifle in his mouth, and then pulled the trigger, whilst the stock rested on the floor. The bullet carried away a portion of the brain as well as part of the skull. Witness learned, upon inquiry as to the cause of his committing so desperate an act, that he had been treated by homœopathic and quack doctors; he was not labouring under any disease. The deceased bore an excellent character, and was much liked by all his officers. Sergeant Barfield confirmed the fact of his having consulted quack doctors, and stated that he complained of being ill at Christmas. He wrote to Messrs. Smith and Co., of Burton Crescent, or of Tavistock Square, witness did not know which, and said he received from them a book called the *Warning Voice*, of which he had read the third and fourth chapters. He paid £1:5:0 for medicine, which he took three times a day. He afterwards became greatly depressed. Witness had often seen him look in a glass, gnash his teeth, stamp his feet, and say, 'I feel I am a ruined man for life.' He also asked, 'What is the quickest death to die.' Witness tried to cheer him up, going with him to various places; and he (witness) was firmly of opinion that the letters he received from Burton Crescent, and his reading of the book referred to, had excited his mind, and caused him to commit suicide. Up to that time, deceased had always been a lively, jovial man among his comrades. A letter was found in his room briefly bidding his comrades farewell. After some other evidence, the coroner summed up, when some of the jury inquired whether, in giving their verdict, it would not be competent for them to express their opinion as to the publication of such books as the one described. The coroner said that the matter in question was beyond the power of the court. The jury then returned a verdict, 'That deceased shot himself while in a state of unsound mind.'"

Two brochures which have just appeared indicate that the same changes which happily are going on in the general, the literary, and the political world, influence also the medical. Thirty years ago, a speech in which religion was introduced in Parliament, or a religious leading article in the *Times*, or a religious article in the quarterlies, was not thought of. How different now. Our leading men in both houses, our first newspaper writers and reviewers,

boldly and reverently, by word and pen, recognise Christianity as the great foundation of all stability and real progress. Very striking is the same change in medicine. In introductory lectures, in our journals, and public utterances of our leading men, there is the same out-spoken recognition of the highest truths. In a marked way, these two memorials of recent deaths indicate this great change. Dr. Risdon Bennett has not only traced the scientific life of Richard Grainger, and the solid work he did for sanitary science, but he has also drawn with discrimination a most delightful character of a good and modest and unselfish Christian, founding all his life's work on the deepest principles. And Dr. Harvey of Aberdeen has, with the warm feelings of friendship, traced the moral qualities of Dr. Williamson—who, just rising into professional eminence, was suddenly cut off by typhus at 40 years of age, to the regret of all who knew him—making to his class the life of their professor and infirmary physician the best clinical lesson as to the importance of always living the highest kind of spiritual life. Neither writer has in any way avoided the fullest expression of religious principles. The former reticence on these matters was, in some cases, from indifference; in others, from the natural dislike to express feelings; but in how many was it from an unmanly fear and shame? Now, the weakest form of cowardice is a disinclination to confess great benefits, and this wholesome avowal is a sign of real progress.

A TESTIMONIAL was lately presented to Mr. Cammack of Benington by the poor, for his attention to them as district medical officer during twenty-one years. On the occasion, Mr. Cammack made the following remarks, which, coming from his long personal experience of Poor-law medical relief, are worthy of especial record here.

"With regard to my successor, he has got more work than one medical officer ought to have; and the pay is far too small for the service. I would not take the district again for £200 a year. It is now £50; the drugs cost all the money, and one horse is altogether unequal to it. The guardians behave badly to their officers generally, and never acknowledge their good deeds. They sit with closed doors, and take every opportunity to humiliate and degrade; and, in order to become in reality the Inquisition, they need only the rack, the thumbscrew, and the boot. The Poor-law Board will never mend them, because they wish to please the guardians who vote them into Parliament. The present race of guardians will not do it, because they wish to be tyrannical, and are afraid that the poor should see who grind them down. It is the people who must open their doors and let in the press. The chairman (Mr. Plummer) was always an advocate for an open board; and, therefore, I am proud to accept this present at his hands. When the people can see for themselves how the Poor-law is administered, and when the medical officers are well paid, and independent of a private practice—for it was wrong to offer a Poor-law appointment as a stepping-stone to a

private practice, because, having got it, the badly paid officer will naturally look to his best interests as his age increases,—when, I say, the officers are properly paid, then may the people be certain of the care and comforts which the poor require. In conclusion, I beg to say this occasion affords me the highest gratification of my life. I may become rich, or I may become poor; but this presentation will ever be my most valued possession."

MR. HENRY SMITH reports, that three fatal cases of dilatation of the urethra for stricture by Mr. Holt's dilator have occurred in King's College Hospital.

OUR readers may be aware that, under the Registration of Deaths Act for Scotland, medical practitioners there are obliged, under penalty, to give a certificate of death. Naturally enough, they resent such an unfair law, but have hitherto vainly attempted to get it repealed. A few weeks ago, a meeting of the Glasgow Medical Association was held in Glasgow, to determine how best to proceed; and it was determined, under the advice of Dr. Christison, to make a strong effort in the next Parliament, and with the general assistance of the profession, to have a new Bill passed on the subject.

WE are glad to find, from the following, that Sir George Grey has himself doubts as to the sanity of the murderer whose case was specially alluded to in last week's JOURNAL.

"Two commissioners have been appointed by her Majesty's Secretary of State for the Home Department to examine into and certify to the mental condition of the murderer Potter at Derby. They examined the Rev. E. W. Foley, the chaplain, and other officers of the prison. Sir George Grey has ordered the respite of Potter for seven days, solely to afford time for the commissioners to inquire into the state of the prisoner's mind."

This case shows also, in a striking manner, the folly of those persons who, as the present Lord Chancellor once did, affirm that an ordinary jury, or any unskilled person, is just as capable of judging of the mental condition of a supposed lunatic as any expert is. We are very pleased to note this act of Sir George Grey's. The only fault which can be found with it is this, that the examination comes late. It should have been made before the trial, so that the evidence of the experts might have gone before the jury. By this plan of deciding the sanity of the prisoner, it is clear that the verdict becomes the verdict of two experts in lunacy, and not the verdict of the jury—a proceeding which is distinctly unconstitutional. We hold, as we have frequently done in these pages, that what justice and humanity demand in all cases where there is a reasonable doubt as to the sanity of the prisoner put on his trial is, that the Government expert should invariably be present to assist justice, and give her the benefit of an impartial opinion. This proceeding of Sir G. Grey's is, we trust, a movement tending in that direction.

SOME time ago, the Administration of Public Instruction in France exempted all Polish students from the expenses attending education in the Faculties and the Lyceums. To increase this Act of generosity, the Committee of the Sorbonne has opened a subscription in order to purchase books and scientific instruments required by the Polish students.

Dr. Stokes's work on Diseases of the Heart and the Aorta has lately been translated into French by Dr. Sénac of Vichy.

M. Roulin has been elected to the Academy of Sciences. He is librarian of the Institute. He was a pupil of Cuvier and Magendie; and in 1821, went out to Columbia as Professor in a chair of Physiology. But he, instead of professing, made a topography of the country for Bolivar. He is the translator into French of Prichard's *Natural History of Man*; and has, we are told, been long engaged in an important work on Pliny.

M. Verneuil informs the French Surgical Society that he has been astonished at the good effects produced by the use of opium after strangulated hernia. It seems that our French brethren have yet to learn the dangers and mischief resulting from the employment of purgatives after that operation!

MM. Eulenburg and Landois (*Berlin. Klinisch. Wochen.*, 1864) have undertaken a number of experiments on the suture of nerves. Their conclusions are unfavourable to the proceeding. They say that the cut ends of nerves, when brought into exact apposition by sutures, have no tendency to unite by first intention. In no case, moreover, has the suture been followed by return of function of the nerve, and even after several weeks. The anatomical examination of the cut nerves showed that the peripheric portion of the nerve had undergone the same changes—degeneration of structure—as when ligature is not applied.

The *Gaz. Méd. de Paris* relates a case of poisoning from atropine. Three grains of sulphate of atropine, mixed with eight *granmes* of lead, formed an ointment which was applied to the raw surface of a blister on the neck.

"A few minutes afterwards, the patient sprang up in agony; he rushed about the room, crying out that he was suffocated; that all his blood was rushing to his head; that all was black before his eyes; and that he felt as if he were being strangled. He tore the plaister from his throat, and fell on the couch with his eyes fixed and his face red. Dysphagia and dyspnoea increased. His pupils were widely dilated; his eyes rolled about convulsively; the conjunctiva injected. All his limbs were convulsed as in violent chorea; respiration very hurried; pulse 140 to 150; he could not speak a word. Nothing could be introduced either into the mouth or the rectum; nor could a vein be opened. The patient became gradually worse, and died about two hours after application of the ointment."

Special Correspondence.

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

It must have often occurred to the mind of those who, coming to Edinburgh, have visited our Royal Infirmary, as a remarkable contradiction, that so great a school of medicine as that of Edinburgh should possess so ill built an Infirmary. On visiting the handsome and expensive buildings which have been erected around Edinburgh for the purpose of affording places of maintenance and instruction for infirm people and destitute children, they must have wondered that more had not been done for the sick poor of our city; and that a more handsome, suitable, and cheerful building had not been provided for their use. The apathy which has for so long a time prevailed upon this subject has, however, fortunately come to a close; and the opinions expressed at a late meeting of the subscribers to the Infirmary, render it certain that ere long our city will possess a hospital more suited to its wants than the present one.

The Royal Infirmary of Edinburgh is partly an old and partly a new building. The medical hospital is almost in the same state in which it was at the time when Cullen and Gregory used to teach it; the surgical hospital, on the other hand, is a comparatively new building, sufficiently well built and convenient. The wards are moderately spacious, well ventilated, and cheerfully lighted; the operating theatres are large and commodious; and the accommodation provided for the surgeons and their assistants is, although limited, sufficient. Far different, however, is the condition of the medical hospital. The wards have low ceilings and small windows, are dreary, badly lighted, badly ventilated, and unprovided with baths. The cubic space allotted to each patient is far too small. The appliances and arrangements for good clinical teaching are also deficient. The rooms attached to the wards, and set apart for the use of the physicians, are excessively small and inconvenient. The lecture-room and pathological theatre are bad; and no properly constructed and appointed pathological laboratory exists.

The chief evils to be pointed to in our medical hospital are connected, however, with the subject of ventilation, and have been well demonstrated by the events of the last few months. A limited epidemic of typhus fever has prevailed in Edinburgh, and the fever wards of the Infirmary have been crowded. It is here (I may say) the custom to separate patients suffering from typhus fever from other patients.

As usual, the fever-wards have been rather more crowded than the other wards. On visiting one of the female fever-wards (Ward 17) lately, I was struck by the close and ill ventilated atmosphere. The ward, which from its construction is not susceptible of even fair ventilation, was crowded with fever patients. The results of this state of matters have been very much what has been noticed in other places and on

other occasions—the attendants have suffered severely. Of four house-physicians, who entered on their duties at the commencement of the winter session, three (Drs. Carmichael, Anderson, and Muirhead) took typhus fever. One of these gentlemen was replaced by one of our most zealous senior students, who has himself become affected with the disease. Of five persons who have this session filled the office of house-physician, four have, therefore, become affected with typhus. The nurses, too, have suffered most severely. Since the commencement of the epidemic many have contracted typhus, and six or seven have died.

The facts are painful, but not startling; and prove how true it is that, unless a very abundant supply of pure air is provided for patients suffering from typhus and other contagious diseases, especially where many are congregated in the same apartment, the danger to attendants is rendered very great. They are facts which have occurred so often, that it is much to be regretted that nothing should have been done to prevent the sad occurrences. Our medical hospital is bad, I have said; still half its wards are left unoccupied. If the cubic space allotted to each patient were at least doubled, I have no doubt that such occurrences as those which I have mentioned would cease; and those to whom the care of patients is allotted would discharge their arduous duties in comparative safety.

An interesting case of acute yellow atrophy of the liver occurred lately in the hospital. A pregnant woman was admitted suffering from profuse hæmatemesis. She was intensely jaundiced, and violently delirious. Immediately after admission, she aborted of twins and expired. Her friends stated that she had only been ill for a week. The progress of the case after admission into the hospital was so rapid, that no definite opinion as to the nature of the case had been formed. The excessively acute nature of the disease occurring in a pregnant woman, the very limited area of hepatic dulness, and the intense jaundice, led Dr. Grainger Stewart, the pathologist to the Infirmary, to express, before commencing an examination of the body, the opinion that the case was one of acute yellow atrophy. The opinion was proved to be true. The liver only weighed 1 lb. 5 oz., and presented the characters of the organ affected with acute yellow atrophy. The bladder contained sixteen ounces of urine; which was analysed, and found to be very rich in leucine and tyrosine. Enough of these substances was separated to enable them to be completely identified by their chemical as well as their microscopic characters. The urine contained 1.8 per cent. of urea, and merely a trace of albumen.

In connection with the Infirmary, I have to announce a fact which will, I am sure, be a source of regret to all who have, within the last few years, studied in Edinburgh. I allude to the approaching retirement of Dr. Warburton Begbie from the office of physician to the hospital. The practice has prevailed here, to limit the duration of the office of physician to the hospital to ten years; and Dr. Begbie's term of office having expired, he is about to retire.

The advantages of the practice are, that it enables a considerable number of men to enjoy the extraordinary opportunities for studying medicine which are afforded by the physicianship to a large hospital. The disadvantages, which, however, fully counterbalance the advantages, are well shown in the present instance. Physicians, who have rendered themselves most popular and useful as clinical teachers, are deprived of their office exactly at the time when they are becoming most fit to discharge its functions with advantage to the students themselves. It is a plan well calculated to train many very good general practitioners and very few very good physicians. Dr. Begbie has now for many years occupied a very high position here, both as an extramural lecturer on Medicine, and as a lecturer on Clinical Medicine in the Infirmary; and his retirement cannot but be looked upon as a great loss to the school of medicine of Edinburgh.

Professor MacLagan's address at the late *conversation* of the College of Surgeons gave general satisfaction. No more appropriate subject could have been chosen for discussion by the Professor of Medical Jurisprudence in the University than the one which he made the basis of his lecture—viz., Civil Incapacity. His *résumé* of the law on this subject was admirably clear; and his arguments for bringing under a certain amount of restraint the class of persons comprised under the foolish term "dipsomaniacs", commended themselves, I am sure, to the great majority of his hearers. The lecture was of such a character, however, that no abstract could possibly do it justice.

We have lately had some very interesting communications presented to the Medico-Chirurgical Society.

Association Intelligence.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

The next meeting will be held at the Infirmary, at Gravesend, on Friday, March 31st, at 3.30 p.m.

Dinner will be ordered at the Yacht Club House, at 5.30 p.m. Tickets 5s. each, exclusive of wine.

C. J. Pinching, Esq., will preside; and papers are promised by M. Adams, Esq. (Clinical Ophthalmic Cases), and by Dr. Bell (Craniotomy).

FREDERICK J. BROWN, M.D., *Hon. Sec.*

Rochester, March 11th, 1865.

WEST SOMERSET BRANCH.

A QUARTERLY Meeting of this Branch will be held at Clarke's Castle Hotel, Taunton, on Wednesday, April 12th, at 7 p.m.

Notice of papers or cases to be communicated should be sent to the Honorary Secretary previous to the meeting.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, March 11th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
WEST SOMERSET. [Quarterly.]	Clarke's Castle Hotel, Taunton.	Wednesday, April 12, 7 P.M.
BATH AND BRISTOL. [Ordinary.]	Victoria Rooms, Clifton.	Thursday, April 13, 7 P.M.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETING.

A MEETING of the East Kent District was held at the Ship Inn, Faversham, on Thursday, March 16th; EDWARD GARRAWAY, Esq., in the Chair. There were fifteen members present.

Papers. The following papers were read and discussed.

1. Variola and Vaccination. By R. S. Francis, Esq.
2. Polypus Uteri and Instrument. By F. E. Barton, Esq.
3. Diabetes Mellitus successfully treated with Permanganate of Potash and Rigid Diet. By Wm. Sankey, Esq.
4. Surgical Scraps. By James Reid, Esq.
5. The Magnesium Light. By R. L. Bowles, Esq.

Reports of Societies.

LIVERPOOL MEDICAL INSTITUTION.

FEBRUARY 23RD, 1865.

J. CAMERON, M.D., Vice-President, in the Chair.

Fracture of the Acetabulum. Mr. HAKES showed, for Mr. LOWNDES (who was unable to be present), a specimen of fracture of the acetabulum. In this case, the pelvis was extensively fractured. One line of fracture extended from the anterior superior spine of the ileum directly downwards behind the acetabulum, entirely through the whole thickness of the bone; this was met by one extending forwards across the upper third of the acetabulum to just above the obturator foramen. Another fracture passed at right angles to this through the horizontal ramus of the pubes, and another through the ramus of the ischium. The bladder was uninjured. The peculiarity in this case was, that these extensive injuries were caused solely by the patient, when drunk, falling on his hip from the top of an omnibus, which was not in motion at the time.

Pyæmia. Mr. RAWDON narrated two cases of pyæmia, and showed specimens of purulent deposit.

Adjourned Discussion on Fever. Dr. BURROWS said he thought the nature of fever was involved in mystery. He believed that many fever-patients, who might now have been living, had died from overstimulation. Alcohol, regarded by many practitioners as the sheet-anchor in the treatment of fever, he declared to be an acrid narcotic stimulant, a true poison, and not possessing a nutritious or life-sustaining power. It was not a tonic; it did not tone or brace up the nervous and vascular systems, but depressed them. Nor did it maintain animal heat; as was proved by the fact that, after the administration of wine or spirits, the temperature of the body gradually diminishes. The similarity of the symptoms caused respectively by alcohol and opium showed that the former was a narcotic. Alcohol was not an element of respiration; neither was it burnt up or consumed in the lungs, as taught by Liebig. As a hydrocarbon, it could not afford plastic material. He alluded to the favourable results of Dr.

Gairdner's treatment of fever without stimulants, contrasting it with that of Dr. Todd, whom he regarded as the champion of the heroic or intoxicating treatment, and who, as he said might be expected, had a very high rate of mortality. He thought that, in many cases of typhus, the stomach had an excellent power of digestion; and that many articles of food usually forbidden might be given with safety. Dr. Stokes had said that fever cannot be cured; that the patient must be kept from dying of exhaustion by food and stimulants. But, even if he thus recognised the use of alcohol, should its deleterious influence be ignored because a great authority recommended it? Dr. Gull did not believe in giving enormous doses of brandy in fever, and also condemned strongly the practice of continual feeding in fever. When a patient recovered from the sinking stage of typhus under the administration of half an ounce of brandy every half-hour, it was because his organism rose superior to the depressing and devitalising influence of brandy, rather than from any remedial virtue attributed to it. He (Dr. Burrows), in his own practice, had tested the value of the stimulating treatment in a very moderate form. In ten cases out of sixty, he had allowed a minimum quantity of wine, and sometimes spirits; four cases of the ten died. The remaining fifty had no alcoholic stimulants, and they did well. So that the result left an impression on his mind that his patients were not benefited by stimulants, and that the non-alcoholic treatment of fever will ensure a less rate of mortality than that which is universally advocated at the present day.

Mr. BAILEY, from his experience in the Toxteth Park Workhouse, thought that, although many cases of typhus might be successfully treated without stimulants, yet these remedies were sometimes absolutely necessary. The quantity he had given varied from four ounces of wine to ten ounces of brandy daily. He had never seen any benefit from henbane, but found opium very useful. In coma, he always used blisters—never gave purgatives; nor did he approve of diaphoretics in typhus.

Dr. TELFORD took exception to Dr. Burrows's view of the physiological action of alcohol, as at variance with the present state of our knowledge on the subject, and inconsistent with the teaching of all leading physiologists of the day. He thought that alcohol was certainly a food; its use as a remedy might often have been abused; but he contended that, when properly administered, instead of increasing excitement as had been alleged, it produced a sedative and calmative effect upon the system. He disagreed with Dr. Shearer, who used it chiefly in the convalescent stage; believing that, when that period of the disease was reached, stimulants were no longer necessary. He thought the hydropathic treatment, recommended by Dr. Burrows, must be exceedingly hazardous; for his observations had satisfied him that sweating was much to be dreaded in typhus.

Dr. BARNES said that alcohol must be a food, because cases were on record, and some had come under his own notice, where individuals had lived upon alcohol alone for many weeks. With reference to thirst in fever, he reminded the Society that two distinct kinds of thirst were recognisable; one being the instinctive appeal of nature for a requisite supply of fluids, and the other arising from nervous exhaustion. The former was relieved by a due supply of water; the latter, which was the thirst of fever, could only be alleviated by wine or alcohol in some form.

Mr. TOWNSON, in his capacity of surgeon to the letter-carriers and to the police force, had recently met with many cases of acute pyrexia, the result of

exposure to sudden transitions of temperature, in which the wet sheet had entirely subdued the disease in two or three days. He deprecated the indiscriminate use of alcohol in the treatment of disease, on moral as well as on medical grounds.

Mr. STEELE, in replying, expressed his disappointment in finding that Dr. Burrows had not brought forward a single clinical fact in support of his sweeping condemnation of alcohol as a remedy, on the score of its poisonous effect upon the system. He thought the action of alcohol as a poison was clearly understood. In large doses, as, for instance, when a man for a wager drank a quart of gin at a draught, it produced almost instant death; or when taken in repeated doses for a long period, as in the case of habitual drunkards, it induced other well known injurious effects. But neither of these modes of action had the remotest connexion with the proper use of alcohol as a remedy in acute disease. Nothing could have been more clearly demonstrated than the fact that alcohol in considerable quantities (say ten or twelve ounces of brandy in twenty-four hours) might be administered for many days in various diseases, without producing any perceptible injury; and he could only suppose that those practitioners who ascribed such injurious effects to the use of alcohol as a remedy must have founded their conclusions upon the injudicious use of this valuable agent in unsuitable cases, either in their own practice, or in that of others. In quoting Dr. Stokes as an authority in the treatment of fever, Dr. Burrows had omitted to state that he was deeply impressed with the great importance of stimulants in fever. It was worthy of notice, that the physicians of Dublin, with scarcely an exception, all recommended the stimulating plan of treatment; and we find, on the authority of Dr. Tweedie, that the mortality from fever in the Irish hospitals is less than that in any other part of the kingdom. During the last forty years, the death-rate had never exceeded 10 per cent. The only safe rule for withholding or giving alcohol, or for regulating the dose, consisted in a due appreciation of the indications present in each case. As he had endeavoured to establish in his paper, typhus must be treated on purely rational principles, by applying appropriate remedies for the regulation of the special functions which presented a marked deviation from normal action; avoiding the use of specifics, and abstaining from violating the laws of Nature by attempting to procure critical evacuations, such as sweating or purging, which the history of the disease amply proved were not the means by which Nature endeavoured to throw off the disease. The course of typhus was gradual throughout, and, as a rule, unattended by crises in the usual acceptation of the term, and not accompanied in most instances by critical discharges of any kind which could be considered salutary or curative.

KING'S COLLEGE HOSPITAL. The performances at the Bijou Theatre have produced £130 to the funds of this hospital.

THE WOUNDED AT BELFAST. Dr. Murney, surgeon to the General Hospital, reports: "I give the experience of 78 medical practitioners, added to which is that derived from the practitioners of the Belfast General and Union Hospitals, and I think the public may be satisfied that the death-roll is complete, and the list of those injured closely approximated to." His return given presents this result:—316 persons suffered more or less seriously; recovered, 219; died, 11; yet under treatment—for this was written on November the 6th—there were, by slight gunshot injuries, 64 sufferers; severe, 34; total from gunshot wounds, 98.

Correspondence.

MEDICAL ERRORS.

LETTER FROM A. W. BARCLAY, M.D.

SIR,—The very temperate article in the last issue of your JOURNAL demands an immediate reply. I am well aware that it was “a serious thing” to select examples from modern writings, when I ventured to point out that medical men are dealing illogically with the evidence which they hold in their hands, of the efficacy or the worthlessness of certain modes of treatment. It has seemed to me a proof that there is yet left in our body some longing after a more perfect knowledge, and some feeling that one's own personal fame and success are not the highest aim of the practitioner, when I have experienced so little personal vituperation as the reward of my boldness. It may indeed be that some people are not so “thin-skinned” as to feel injured by the attack which has been made on them; but I am more disposed to regard their silence as an indication of good feeling and love of truth, when I read such an article as that on “change of type in disease”.

I may first remind Dr. Markham that the lecture to which he refers was both written and delivered before his own were published; and, though I had the advantage of hearing them at the College, yet perhaps I did not carry away such a clear idea of their scope as was subsequently obtained from their perusal. Still it did not seem necessary to modify the reference to his views, because, in the few words in which I alluded to them, the weak part of his argument was directly referred to. I confess that, as his error, if error there be, is not one of inductive reasoning, it ought to have had no place in my lectures; and, in truth, the allusion was prompted chiefly by the accident that my friend Dr. Markham had selected the “uses of blood-letting in disease” as the subject of his Gulstonian Lectures in the same year in which I was asked to deliver the Lumleian; and his antipathy to the theory of “change of type” was already pretty generally known. It is one of those speculations in which medical men are too apt to indulge; and it has, unfortunately, been too much mixed up with the consideration of venesection.

There are two points in Dr. Markham's remarks which especially call for notice; viz., my own allusion to the subject, and his explanation of the sense in which he uses the words. On each of these I have a few remarks to make.

It seems to me that those who assert that there is no change of type are fairly bound to give us an explanation of such remarkable circumstances as those referred to, which, *primi facie*, point so distinctly to some change having occurred since the days when an epidemic of plague was looked on as no very extraordinary circumstance, and an epidemic of cholera was unknown. It would cause us some surprise if syphilis were to disappear; or if small-pox, in spite of the neglect of vaccination which still permits its ravages in a modified form, were to be limited for the future to some special region. For my own part, I feel that the incursion of cholera is a very curious phenomenon in this age, and quite as inexplicable as an epidemic of yellow fever would be. It is, indeed, possible that improved sanitary arrangements may be sufficient to explain the absence of plague. But do they also account for the ravages of cholera? I confess that, in my opinion, they do not explain either. There seems to me to be some circumstance yet undiscovered necessary to a satisfactory explanation

tion of these facts; and the suggestion of a “change of type” is one which has been made theoretically to fill the void. It may not do so in a very satisfactory manner, and certainly no inductive argument has been employed either to prove or disprove the theory.

Dr. Markham goes on to say, that he believes we are using the term in a different sense, and he proceeds to give us anew his own definition. I have studied it again, and do not find that I have ever given the words any other interpretation; and I may fairly retort on my friend, that he has misconceived my meaning, and has attributed to me views which I never did entertain. More than this; it seems that he has himself employed wholly erroneous terms in speaking of the cases cited. When I say, “Cholera was unknown in Europe forty years ago”, he substitutes the words, “Whenever a new disease appears”. When I say, “Plague has entirely ceased to spread beyond the regions of the Levant”, he transmutes it into, “Whenever an old disease disappears”. Surely, this is not fair argument. Cholera is not a new disease; plague has not disappeared. From this, he flies off to the potato, where I decline to follow him.

The fair and simple interpretation of my language surely is this. The susceptibility to cholera has within forty years become such that the disease has travelled round and round the world more than once during that period—which it never did before, long as it has been known; whereas the susceptibility to plague has become so much less than it used to be, that we now never hear of it beyond the shores of the Levant. These circumstances may indicate the existence of “change of type”; or, in other words, “not any imaginative alteration in the essential nature of the diseases themselves; but some change in the condition of the body which is the subject of the diseases.”

As Dr. Markham has gone into hypothetical matters, I would ask him whether some such explanation would not be necessary if inflammation of the lungs should occur as an epidemic in the human race? and I may also ask him, whether veterinary surgeons are not perhaps justified in believing that such a change has taken place, when they have so constantly to encounter the so-called “contagious pleuro-pneumonia” of cattle? a disease in which blood-letting and blistering, as I understand, are wholly out of the question. Possibly, this may be an entirely new disease, like the potato-blight or the vine-disease; and I quite agree with Dr. Markham in holding that the springing up of some entirely new form of malady is no evidence of a “change of type”. It may possibly spring out of the “change in the condition of the body”, if any such change have occurred; but clearly it cannot be taken as proof of any alteration, so long as we are in ignorance of the circumstance which has given origin to it, or whether any change was necessary to its development.

I would only beg to remind your readers once more, that the question raised by Dr. Markham was not essentially connected with the subject of my lectures. I have only ventured to criticise theories which were supposed to be supported by inductive arguments; as my object was to endeavour to stimulate the writers of the day to seek legitimate proof of their conclusions before attempting to add them to our stock of medical literature. Abstract speculation, such as the theory involved in the question of “change of type in disease”, may serve to sharpen the logical acumen of those who engage in its discussion; but does not practically teach us anything of the causes or consequences, or the most appropriate treatment of disease. I am, etc.,

A. W. BARCLAY.

Bruton Street, March 21, 1865.

POOR-LAW MEDICAL REFORM.

LETTER FROM RICHARD GRIFFIN, Esq.

SIR,—I shall feel obliged by your affording me space for the annexed letter from the Poor-law Board, it being the reply to one dated March 6th, and inserted in your JOURNAL of the 11th inst. It has been said, that "language was given to enable us to conceal our thoughts"; and this is verified by the wording of the letter from the Board. I believe our appointments and contracts are two different things; and, even where the former are permanent, the latter can at any time be altered; therefore, perhaps, it may be intended to enter into new contracts with the medical officers, and readjust on equitable principles all the salaries. I trust it may be so.

Allow me to explain that the M.P., to whom I referred in my last letter as not having replied to my communications since January 31st, has forwarded to me a letter dated March 6th, in which he explains that domestic affliction and absence from England were the causes of the long delay. He also says: "I quite agree with you that some such measure as that drawn by you should become the law of the land, as the present state of the law is not only unsatisfactory, but unjust to the profession and the poor. When you first addressed me on the subject of my introducing a Bill this session, I thought I should be able to do so with effect; but I regret that circumstances will prevent my taking an active part during the present session. — is greatly opposed to an alteration of the law, and county members will not hear of any alteration. There must be something very wrong in the profession, when it is unable to make itself felt in a political sense throughout the country. Attorneys have their organisation; and, when any question relating to them comes before the House, it is *not only heard*, but duly considered."

From the above quotation, I greatly fear that nothing can be done by the Poor-law medical officers this session. If, however, the Poor-law Board still continue obdurate, we must, like the lawyers, become politicians, and at the next election refuse to give a vote without a promise that each member will aid in obtaining from Parliament an equitable adjustment of the claims of the Poor-law medical officers. This is all that we ask; and no honourable man ought to refuse it. I trust the medical men of Wolverhampton will insist upon Mr. Villiers giving this pledge, as I cannot but feel that he is our great opponent. I am, etc., RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, March 20th, 1865.

[COPY.]

Poor-law Board, Whitehall, March 18th, 1865.

SIR,—I am directed by the Poor-law Board to acknowledge the receipt of your letter of the 7th inst., on the subject of the supply of expensive medicines, when required in the medical treatment of sick paupers.

The Board direct me to inform you that they have given much consideration to the subject referred to in your communication, and have caused various inquiries to be made as to the best course of proceeding to carry into effect the recommendation of the Committee on Poor Relief on this point.

In the cases of new contracts which are entered into by boards of guardians with their medical officers, the Board are endeavouring to secure in the most practicable manner the objects suggested by the Committee; and they will not lose sight of the subject, if any further proceedings for the purpose should appear to be practicable.

I am, sir, your obedient servant,
ENFIELD, Secretary.

DR. FORBES WINSLOW'S INDISCREET FRIENDS.

LETTER FROM C. LOCKHART ROBERTSON, M.D.

SIR,—You add a note to my last letter, in which I ask Dr. Forbes Winslow whether he approves of the laudation of his "right and scientific judgment" made in the *Observer* of March 12th, that "Dr. Winslow will naturally say that he is not responsible for the indiscretions of other people."

That same objectionable paragraph has been on duty last week in all the Derby papers. Who sent it there? That same indiscreet friend? Verily, so devoted and indiscreet a henchman is he, that memory at once suggests the eloquent though anonymous author of the *Voice from Derby to Bedlam* as the culprit. Whether I be right, however, or not, in this guess, I really must ask you to try and induce Dr. Winslow to exercise a greater supervision over the zeal of his friends in the press. In an address which I heard him deliver in 1857, he says, after lamenting the fact that our position as psychologists is not what we have a right to expect or are entitled to claim, "there must be something rotten in the State to justify such a sad condition of things." I desire herein to call his attention to these rotten laudations of his "right and scientific judgment" in the London and provincial public papers. I am, etc.

C. L. ROBERTSON, M.D. Cantab.

Hayward's Heath, March 22nd, 1865.

COLD WATER INJECTIONS.

LETTER FROM HENRY E. NORRIS, Esq.

SIR,—In the last number of your JOURNAL, I see a letter from Mr. Roper of Croydon, advocating the use of cold water injections in cases of *post partum* hæmorrhage. I can bear testimony to the efficacy of the remedy, having not unfrequently had occasion to administer it myself under similar circumstances. I have found, however, the addition of brandy to the water sometimes necessary; and in one case, I remember, not having with me the necessary instrument, I found the introduction of ice into the uterus of the greatest service. In fact, I have no hesitation in saying that by it the patient's life was saved.

I was a long distance from home, and several miles from any brother practitioner; the patient was almost in *extremis*; and I had no syringe with me; and all other means at command, including the administration of the ergot of rye, had failed to produce the necessary contraction of the womb, so as to arrest the hæmorrhage. There happened to be a frost the same night; and I sent a servant out with lantern and candle, to collect ice in the pools around. In a short time, I had a basin of ice at command, which I introduced bit by bit into the womb. The effect was soon perceived. Permanent contraction of the viscous very soon came on, and the woman did very well.

As this case was a very peculiar one, I will just mention that the woman had sustained a short time before a rupture or laceration of the linea alba, extending very nearly from the umbilicus to the pubes. She was at the time in a very atonic state, and her animal fibre was generally in a very lax condition; and, moreover, she had been enormously enlarged previously, and, in fact, had been confined of twins. She, however, recovered sufficiently to produce another child at the end of two years, and has had two or three since; but her accouchements are invariably attended by more or less disposition to flooding, consequent on want of proper contraction of the womb.

I have on some occasions found that repeated

shocks from the galvano-magnetic machine produce contraction and arrest uterine hemorrhage, when cold water injections have entirely failed to do so.

Two of the worst and most obstinate cases of flooding after delivery I remember treating happened, I believe, from my own previous treatment of the cases. I had been recommended by a friend to try the application of liquor belladonnae when great rigidity of the os uteri existed. Happening shortly afterwards to get two cases of this kind, I used his remedy, with immediate effect. The os uteri dilated, and the labour was speedily over. But as in both cases the patients suffered from *post partum* flooding, which I arrested with great difficulty, I have never again tried the remedy, as it appeared to me to temporarily paralyse the muscular fibres about the os uteri, which no means that I used would stimulate to contraction. I thought the first case might be accidental; but, as the second case was followed by exactly the same effects, I concluded it best to discontinue the practice.

In my practice, I have found long continued pressure with the hand externally over the womb, grasping and keeping it closed; the administration of the essence or tincture of ergot of rye internally (and I may mention that prepared by Mr. T. C. Jobson, 87, Lever Street, Goswell Street, E.C., I have found most to be depended on); with, if necessary, the injection of cold water into the uterus; with the addition of brandy, if required,—to be the most effectual means of producing uterine contraction. If extreme faintness be present, I give brandy with cold water, or, in some cases, undiluted, according to the urgency of the case. I am, etc., HENRY E. NORRIS.

Charmouth, Dorset, March 15th, 1865.

IRIDECTOMY AND GLAUCOMA.

LETTER FROM J. W. HULKE, ESQ.

SIR,—I send, for insertion in the JOURNAL, a note of a case of *glaucoma with very acute inflammation*, in which iridectomy was performed last spring, during the discussion respecting the value of this operation in glaucoma. I leave the case, without comment, to speak for itself. I am, etc.,

J. W. HULKE.

10, Old Burlington Street, March 7th, 1865.

A lady, aged 63, stout, but active, of simple habits, and in excellent health, was seized with violent pain in her left eye, blindness, intense redness, and swelling of the eyelids. To use her own words, "My sight went in a moment. The pain was most intense. . . . I felt sick, but did not vomit." A week afterwards, her right eye was similarly attacked, in the same sudden manner. An eminent physician now saw her, said it was gouty inflammation, and prescribed a lotion. Some days later, she came under the care of Mr. J. G. Forbes, who, after watching the case for upwards of a week, was led, from the inefficiency of the treatment and the extreme loss of vision, to suspect the existence of glaucoma, and request me to see her.

I found both eyeballs extremely hard and very painful, with occasional more intense paroxysms. The conjunctivæ were scarlet and oedematous; the pupils dilated and motionless; and the corneæ so dull that an ophthalmoscopic examination of the retina was not possible. The visual fields were very contracted, and acuity of vision was so diminished that a candle-flame was faintly perceived, and became invisible when moved a few inches in any direction from the axis. I recommended immediate iridectomy, to which she gladly acceded. Mr. Forbes at once gave chloroform, and I operated, removing a

large piece from the upper part of each iris. Three hours afterwards, she was free from pain, and said that her eyes felt only sore. Next day, the redness was less, and the wound had closed. Two days later, she could distinguish my hand, and, the day after, discern the fingers. Her sight gradually returned; and now, ten months after the iridectomy, she reads "minion" type with the right and "two-line great primer" with the left eye, and writes remarkably well and clearly.

Medical News.

APOTHECARIES' HALL. On March 16th, 1865, the following Licentiates were admitted:—

Constable, John Henry Caffry, St. George's Road, Southwark
Craigie, John, Fairlight Villas, Hackney
Hendry, Daniel, Liverpool
Snow, William Vicary, Vicarage Lawn, Barnstable

At the same Court, the following passed the first examination:—

Buerton, William, St. George's Hospital
Ceely, Robert Walter, London Hospital
Croft, John Henry, Guy's Hospital
Grey, John Henry, London Hospital
Goodworth, Roger Portington, London Hospital
Jackson, Mowbray, St. Bartholomew's Hospital

As an Assistant:—

Brown, William, Blackstone Street, Liverpool

APPOINTMENTS.

ARMSTRONG, Alexander, M.D., Deputy Inspector-General of Hospitals, to Haslar Hospital.

ARMY.

BRADSHAW, Assistant-Surgeon A. F., Rifle Brigade, to be Assistant-Surgeon Royal Artillery, *vice* A. C. M'Favish.
GUNN, Staff-Assistant-Surgeon F. L. G., to be Staff-Surgeon, *vice* H. S. E. Schroeder, M.D.
MAHER, Assistant-Surgeon V., 41st Foot, to be Staff-Assistant-Surgeon, *vice* N. Norris.
NORRIS, Staff-Assistant-Surgeon N., to be Assistant-Surgeon 41st Foot, *vice* V. Maher.

ROYAL NAVY.

BROSTER, E. B., Esq., Assistant-Surgeon, to the *Sharpshooter*.
CRAIG, Hugh B., M.D., Acting Assistant-Surgeon (additional), to the *Macedon*.
COCKIN, John, Esq., Surgeon, to the *St. Vincent*.
DAVIDSON, S. M.D., Acting Assistant-Surgeon, to the *Stromboli*.
DOBBIN, John W., Esq., Assistant-Surgeon (addit.), to the *Victory*.
HARRISON, G. W. L., Esq., Assistant-Surgeon, to the *Sharpshooter*.
HUNTER, John M., Esq., Assistant-Surgeon, to the *Dee*.
INGLIS, John, Esq., Surgeon, to the *Egmont*.
MESSER, Adam B., Esq., Surgeon, to the *Perseus*.
MITCHELL, John T., Esq., Assistant-Surgeon (additional), to the *Formidable*.
MULLIN, Albert A., Esq., Assistant-Surgeon, to the *Spider*.
WELLS, S. S. D., Esq., Surgeon, to the *Britannia*.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

BOWES, Lt., Esq., to be Assistant-Surgeon 15th Yorkshire R.V.
GIBB, G., M.D., to be Honorary Assistant-Surgeon 1st Dumfriesshire R.V.
WHITTLE, A., Esq., to be Surgeon 51st Lancashire R.V.
WYNTER, D. Lt., Esq., to be Assistant-Surg. 10th Warwickshire R.V.

DEATHS.

BRETT. On March 19th, at Watford, aged 31, Fanny Elizabeth, wife of Alfred T. Brett, M.D.
FENTON. On March 22nd, at Eyam Terrace, Derbyshire, aged 13, George, son of Thomas Fenton, Esq.
JAMES, William Withall, Esq., Surgeon to the Devon and Exeter Hospital, etc., at Exmouth, aged 41, on March 17.

ARMY MEDICAL ESTIMATE. A vote of £246,544 for medical establishments has been agreed to in the House of Commons.

DR. ARMSTRONG, Deputy Inspector-General Royal Navy, has been appointed a member of the executive and finance committee of the Patriotic Fund.

A DUCAL AUTOPSY. The autopsy of the body of the Duke de Morny was performed, at the express wish of the Emperor, by M. Robin. The operation took fourteen hours to perform; the result has been to ascertain the cause of his death to have been poverty of blood, resulting from a lesion of the pancreas and a disease of the liver. The brain weighed 1,532 grammes—that is, 232 grammes over the average.

GLASGOW MEDICO-CHIRURGICAL SOCIETY. At a meeting of the Glasgow Medico-Chirurgical Society, held on Tuesday, March 14th, the following gentlemen were elected office-bearers for the present year. *President*—C. Ritchie, M.D. *Vice-Presidents*—R. S. Orr, M.D.; R. Paterson, M.D. *Council*—J. G. Wilson, M.D.; W. Prichard, M.D.; J. D. McLaren, M.D.; W. Naismyth, M.D.; W. T. Gairdner, M.D.; G. Yeaman, M.D. *Secretaries*—J. Adams, M.D.; G. H. B. Macleod, M.D. *Treasurer*—J. Coats, M.D.

CHEMISTS AND DRUGGISTS. In the House of Commons, on the 17th inst., Sir F. Kelly moved, in committee of the wholehouse, that the chairman be directed to move the house that leave be given to bring in a bill to regulate the qualifications of chemists and druggists. The bill was subsequently brought in and read a first time. On Tuesday last, Sir J. Shelley, in committee of the whole house, moved a resolution that leave be given to bring in a bill for regulating the qualifications of chemists and druggists in England and Wales, and suggested that the measure, and also a similar one which had been brought in by the hon. and learned member for Suffolk (Sir F. Kelly), should be referred to a select committee. Sir F. Kelly consented to the course proposed, though he understood that this bill was more extensive in its operation than the one which he had himself proposed, and he should be sorry that legislation should be prevented by trying to do too much. He trusted, however, that they might from the two measures frame a satisfactory bill. The resolution was agreed to. Sir F. Kelly's bill requires that all persons commencing business after this year shall either be pharmaceutical chemists, or be examined and passed by the examiners under the Pharmacy Act, and registered as chemists and druggists under this bill. But chemists and druggists in business before the end of this year, and their assistants, if of age, are to be entitled to be registered without examination. The register is to be printed for sale annually. The fees for examination and registration are to be fixed by a bye-law, to be made in accordance with the Pharmacy Act.

CHARGE AGAINST A MEDICAL MAN. A medical man in Glasgow, Dr. E. W. Pritchard, is in custody in consequence of suspicions attending the death of his wife. It appears that Mrs. Pritchard some four weeks ago was seized with illness, her complaint being described by her husband as gastric fever. Mrs. Taylor, her mother-in-law, came from Edinburgh to wait upon her, and of course resided in Dr. Pritchard's house. About three weeks since Mrs. Taylor was one evening suddenly seized with severe illness, and despite the efforts of a medical gentleman whose aid was called in died within a few hours. Her body was removed to Edinburgh, and there interred. As for Mrs. Pritchard, she appeared for some time to be in a fair way of recovery. At the end of last week, however, she had a relapse, when she was attended by the same doctor whose services had been engaged for her mother. But in this case also medical skill proved of no avail, and death supervened somewhat suddenly on Saturday last. Dr. Pritchard conveyed his wife's remains to Edinburgh on Monday, although the interment was not intended to take place till Thursday. Meanwhile the attention of the authori-

ties had been called to the case, and the doctor, on his return from Edinburgh on Monday evening, was apprehended by the police at the railway station. On Tuesday morning, although he was not taken before the magistrates, it was intimated publicly in court that he was detained for examination as to the sudden death of his wife, and the case was forthwith remitted to the Sheriff. The *post mortem* examination of Mrs. Pritchard's body, which was made in Edinburgh on Tuesday afternoon, resulted, it is understood, in the decision of Drs. MacLagan and Littlejohn, that there were no natural appearances to account for death. The stomach and its contents were accordingly handed over to Dr. MacLagan for chemical analysis.

THE LATE MR. W. W. JAMES. By the death of Mr. W. W. James (announced in our obituary), one of the surgeons of the Devon and Exeter Hospital becomes vacant, as also the surgeoncy of the Devon County Prisons and of St. John's Hospital. Mr. W. W. James has left by will to his trustees, Dr. Shapter and Mr. Bremridge, the sum of £2000; the interest accruing from which is first to be applied to certain specified family purposes. It is then to be paid over to the Governors of the Devon and Exeter Hospital, to form a fund, the interest of which is to be annually equally divided between the four surgeons of this institution. Mr. James, in making this bequest, desired to give substantial expression to his opinion that the time and energies of the surgeons of this institution were largely called upon by its duties; and that there should be some pecuniary rewards for their labours in its behalf.

DEATH OF DR. BLEGBOROUGH. Dr. Blegborough expired at his residence on the 12th inst., at the age of 85 years. He practised in London about the year 1824, and has since resided in Richmond, where he sought retirement from the arduous duties of his profession. His practice in London was very extensive. He lived in Bridge Street, Blackfriars, and some will remember him in the metropolis as one of the best and kindest of men. Of late years, when his great experience as a physician could be of service, he was induced to employ his medical skill in case of need, and at the request of his friends, or in any case of immediate danger, his assistance was not asked in vain; but he did not, for several years past, make his profession the means of emolument, and he invariably refused to receive any pecuniary reward for his attendance. His charity was well known, and next to his personal friends, there are none who will miss him so much as the poor of Richmond. The amount which he dispensed for charitable purposes was very considerable, and his generosity was not confined to this borough. Besides those liberal gifts to his needy brethren which we have little doubt he bestowed and without sufficient ostentation to make them known to the world, he has bequeathed several noble donations to institutions for the relief of the sufferings of those in whom it would appear he seldom lost an opportunity of showing his sympathies. Amongst these are £1,000 to the York Infirmary, £1,000 to the York Blind Asylum, £1,000 to the Doncaster Deaf and Dumb Institution. His annual distribution of coal to the amount of £100 to the poor of Richmond is well known, as also the fact of his having been a large subscriber to the funds for the restoration of the parish church. He has bequeathed legacies of £500 each to his servants. His many acts of kindness and generosity are sufficient to speak for themselves, and nothing that we could say in this short notice would tend to increase the affection with which he will be remembered; and perhaps the most fitting monument that he can receive will be the esteem

with which his name will be treasured in the hearts of those who knew and experienced his goodness whenever an appeal was made to his sympathies. (*Richmond Chronicle*.)

EXTRAORDINARY FRAUD. At the Mayo assizes Dr. Barrett, M.D., registrar of births and deaths to the Castlebar Poor Law Union, has pleaded guilty to a charge of extraordinary fraud. He literally drew upon his imagination for his records, and, in order to increase his fees, entered in the register a number of births and deaths that had never taken place. The Crown did not press for punishment; but allowed Dr. Barrett to go out on his own recognizance, for the following reasons. It was the first offence of the kind in Ireland; he had not made a false entry of any actual birth or death, he was a married man with several children depending on him for support, he had lost all his situations, and had been in prison for six months. Judge Christian, without assuming the responsibility of this lenient course, gave it his sanction.

MORTALITY IN PARIS. The following statistics of the diminished mortality in Paris extend over a period of twenty-four years. In 1841 the population of twelve parishes amounted to 935,000 persons, and one death in 36 is proved. In 1864 the number of deaths was one in 40. Wide streets and open boulevards have replaced the narrow passages and crowded courts of old Paris. Also there is an immense increase in the quantity of water. In 1840 65,000 cubic metres were distributed in twenty-four hours, whereas in 1863 133,258 cubic metres were supplied. In 1840 there were 36,000 metres of sewers, whereas in 1863 the sewers of Paris attained the surprising length of 350,000 metres—that is 90 leagues. Another cause of the increased salubrity of Paris is the immense number of squares and open gardens created for the use of the people.

THE STREETS OF LONDON. The Registrar-General recently called attention to the deplorable condition of the London streets. The monthly report of the medical officer of health for Marylebone contains the following remarks on the same subject. "A feature in parochial management not yet realised, but greatly needed, is the adoption of some efficient system of cleansing our streets and thoroughfares. The sanitary advantages to be derived from dry pavements and well swept crossings cannot be overrated. How many hundreds of ill-clad and badly shod pedestrians catch cold from wet feet and damp exhalations, and thus lay the foundation of fatal pulmonary disease? What a large amount of failing strength among the infirm and aged is expended in toiling through the thick, tenacious mud that gives to London an unenviable notoriety which might otherwise be husbanded for useful and profitable labour; and how incessant is the work imposed upon poor industrious women with large families, who, appreciating the blessings of cleanliness in their humble dwellings, strive, but strive in vain, against the all-pervading dirt and mire! A liberal and judicious expenditure in this department would surely prove a wise economy, a saving in health alone, irrespective of all other considerations, which, if estimated merely at its money value, would suffice to pay back the additional outlay ten times over. It is to be deplored that, with the local powers possessed by the parishes and district boards of this metropolis, so great a defect in our sanitary arrangements should be permitted to exist. The streets, markets, and public places of Paris are models of cleanliness; there the channels are washed twice a day, and every morning, before the inhabitants are stirring, every particle of dirt and refuse is removed."

THE ZOOLOGICAL SOCIETY has resolved to appoint a Prosector, with a salary of £250 a year. His duties will be as follows. "1. To attend daily at the dissecting-room in the Society's gardens, from 10 A.M. to 4 P.M. 2. To take charge from the Superintendent of the bodies of all animals that die in the Society's menagerie, and to keep an accurate register of the same. 3. To dispose of each body according to the instructions of the Zootomical Committee of the Council. 4. If the Zootomical Committee shall have assigned it entire to any institution or individual, to take measures that it may reach its destination as speedily as possible, and to record the fact of its having been sent. 4. If the Committee shall have merely disposed of the skin, or skeleton, or both, to make an examination, with a view to determine the cause of death, so far as such examination can be made without injury to the skin or skeleton, and to record full notes of the examination in a book to be kept for that purpose—the book from time to time to be inspected by the Committee. 6. To make such other dissections, or perform such other anatomical or physiological work as the Zootomical Committee may from time to time direct, and to keep an accurate record of these dissections and observations. Such of them as may be approved of by the Committee, shall be presented by the Prosector to the Society at its scientific meetings, for publication in the *Proceedings or Transactions*, but the Prosector shall not make public his observations through any channel without the express permission of the Zootomical Committee."

TO CORRESPONDENTS.

* * All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

PROFESSOR BOECK'S letter on Syphilisation shall appear next week.

ROYAL COLLEGE OF SURGEONS.—It is stated that the "Proceedings" of the Royal College of Surgeons are in the press, and will be shortly published.

NEW MEDICAL ACT.—SIR: I would suggest that in any future amendment of the Medical Act, a clause should be inserted to the following effect, viz.:—

"The occupier of any premises shall be liable to be fined, etc., who shall have the word 'surgery' written or printed upon the door, fanlight, or any other portion thereof, or exhibited in a window, unless there be a name stating whose surgery it is, the resident not being a qualified medical man."

In this neighbourhood the Medical Act is evaded by two unqualified men; they each exhibit the word surgery on the fanlight, and their own name on the door, keep their vehicles, and lead the public to believe they are qualified practitioners.

March 20th, 1865.

I am, etc., M.R.C.S., ETC.

SECTION OF THE TENDO ACHILLIS.—SIR: You state in the number of last week, that the late Dr. Stoess of Strasburg was the first who practised the section of the tendo Achillis in France; but I beg to state that this is an error, as the operation was first performed in France by Delpech.

London, March 21st, 1865.

I am, etc., H. D.

COMMUNICATIONS have been received from:—MR. JONATHAN HUTCHINSON; DR. W. H. O. SANKEY; DR. RADFORD; DR. JOHN THOMPSON; MR. PICK; MR. DAYMAN; MR. J. STONE; PROFESSOR BOECK; MR. J. WATKINSON; DR. B. FOSTER; MR. RICHARD GRIFFIN; DR. GILCHRIST; DR. DURRANT; DR. BULLAR; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; MR. J. WINDSOR; DR. ROBERTSON; DR. DICK; MR. JABEZ HOGG; DR. A. W. BARCLAY; PROFESSOR SIMPSON; MR. ARTHUR RANSOME; MR. R. L. BOWLES; DR. SHAPTER; MR. FENTON; and A PUPIL OF PROFESSOR SPENCE.

Observations

ON THE

CÆSAREAN SECTION AND ON OTHER OBSTETRIC OPERATIONS.

BY

THOMAS RADFORD, M.D.,

F.R.C.P. EDIN. AND F.R.C.S. ENG., ETC.,

HONORARY CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL,
MANCHESTER.

CHAPTER VI.

*Operations intended to save the Life of the Mother,
and also that of the Infant. (Concluded.)*

III.—On *Premature Labour*. The induction of premature labour was first performed by Dr. Macaulay in England in the year 1756. But, although this is the fact, and though the importance of the operation is acknowledged and its adoption sanctioned by the most eminent British obstetricians, yet, if we consult statistics, we shall find it has only been limitedly employed, in comparison with its practical importance. There is no recognition of this practice in the statute-book, to distinguish it from that abuse of it which is committed for criminal purposes. In this respect, it is estimated in the same way as some other operations which I shall consider in the subsequent part of these remarks, being only sanctioned by the law of custom. This is an unwise legislative omission, because it permits wicked men to cover their crimes under the pretension of a legitimate act. On this account, therefore, great caution should be exercised whenever this operation is intended to be performed. It is justifiable on moral grounds, and it is approved of on every professional and social principle. The object of its performance is noble and humane, as the lives of those infants are saved by it which must otherwise be destroyed; whilst at the same time, according to my experience, the woman incurs little risk, if any more than that which is contingent on ordinary labour, and very much less than that which results from craniotomy. But, notwithstanding its high value, it ought never to be performed without great necessity, nor without having been first well considered and sanctioned by a consultation.

It is a simple, safe, and efficacious operation, and, if duly performed, infants not to be computed in number would be born alive; it saves when its alternative assuredly destroys. It is not intended to supersede the Cæsaean section, for no right-minded practitioner would ever think of adopting such a course if the operation now under consideration were eligible; but the great object to keep in view is, to prevent as far as possible the performance of craniotomy. It has, however, been asserted by one writer, "that premature labour should never be attempted before it has been proved, by the event of one or more destructive foetal births, that the pelvis was so much distorted that life must have been unavoidably sacrificed before delivery could be accomplished, because a single fatal instance is not always a sufficient warrant for the operation."

The destruction of one infant ought to satisfy every obstetrician that premature labour in a future pregnancy ought to be induced, if the pelvis is so

contracted that one full grown cannot possibly pass through it. A second life ought never to be sacrificed in such a case. But, in case such a pelvic deformity were suspected, and, after a careful examination, proved to exist, it would be highly improper to allow a woman to go on to the full period of pregnancy, in order to prove by craniotomy the necessity for the induction of premature labour.

The longer gestation is allowed to proceed before the performance of this operation, a greater chance of living is given to the infant; but the precise period at which labour ought to be induced must entirely depend on the degree of positive or relative diminution in the pelvis.

The express object of the obstetrician is to save the infant; and, therefore, he should allow a sufficient length of time for its intrauterine existence, so as to enable it to support an extrauterine life. Most writers assert that it is not viable before the end of the seventh month of pregnancy; but I think it will live after a shorter sojourn in the uterus. Well authenticated cases are recorded of infants having lived who were born at six and at six and a half months. Similar cases have occurred in my own practice, and also in that of some of my British and foreign medical friends.

The following table shows the progressive development of the foetal head which takes place during pregnancy, from the fifth and half month up to the ninth.

Date of pregnancy.	Bi-parietal diameter.	Occipito-frontal diameter.
At 5½ months	2½ inches	3½ inches
At 6 months	2¾ inches	3¾ inches
At 6½ months	2¾ inches	3¾ inches
At 7 months	2¾ inches	3¾ inches
At 7½ months	2¾ inches	3¾ inches
At 8 months	3 inches	4 inches
At 9 months	3½ inches	4½ inches

The above measurements strikingly show that the size of the head will be found greater or less according to the period of pregnancy at which artificial labour is brought on; and the size of each must be relatively compared with the varying pelvic cavity through which any of them have to pass. The pelvis may be only just so much diminished in size as not to permit the passage of an infant at the seventh month, and yet allow an easy transmission of one at the sixth or even at the sixth and a half month. A very slight addition of bulk to the head, or a very little diminution of space in the pelvis, will mechanically oppose the passage of the infant; and, on the contrary, a very little comparative difference in either case will render its egress easy. This fact is exemplified by a very simple experiment. Add a little gold-beater's skin to a ball turned to the size or of the diameter of the space it would only just pass through, and this slight addition will be found sufficient to resist its passage.

In correspondence, then, with the facts just mentioned, I have ventured to recommend for consideration the induction of labour at the end of the sixth and the end of the sixth and a half months of pregnancy, in those cases in which the pelvic space is below that which is required for the safe delivery of an infant at the end of the seventh month.

The gradual development of the infant's head during pregnancy should never be forgotten when this operation is contemplated; and it is of equal im-

portance accurately to measure the pelvis, in order that a correct relative comparison may be made. But if the calculation has been erroneous, and the head cannot pass unassisted, then, under such circumstances, the long forceps ought to be applied.

The value of the long forceps should not in all such cases be merely estimated as an accidental contingent auxiliary power; but, in some, this instrument from the first should be considered and accepted as an essential means for delivery.

The combination of these two operations will enable the obstetrician to safely extract a living infant which must otherwise be destroyed. This operation stands preeminently forward as conservative; and, as its mission is for the saving of both the lives, perhaps it may be said to be specially intended for the salvation of the infant which must otherwise be destroyed. We ought, in every case of difficult labour, whether terminated by forceps, or by turning, or by craniotomy, strictly and minutely to examine and ascertain the precise measurement of the pelvis, so as to be able to compute the advantages and disadvantages which are contingent on any of these modes of delivery, when compared to those of the induction of premature labour.

My remarks have been more particularly directed to the induction of premature labour in cases in which the pelvis is positively distorted. But it must be understood that, in all cases in which there is such a relative disproportion between the head of a full-grown infant and the available pelvic space, that the head cannot pass without a reduction of the size by craniotomy, while the pelvis is of such capacity as would permit one less (still viable) advanced to pass through at the above specified periods, premature labour ought to be induced; such as when the pelvis is regular in shape and symmetrical, yet too small from want of development; or when an exostosis has grown from some portion of it, or fixed solid tumours exist within it. It is also sometimes desirable to shorten the period of pregnancy in some diseases which threaten the life of the woman, as in some cases of albuminuria, or when violent uncontrollable vomiting exists.

If this operation be undertaken, subject to the restriction inculcated in these remarks, there can be no question as to the morality of the practice in such cases.

A very important object in medical jurisprudence is also gained by the practice of inducing premature labour at these specified periods of pregnancy. According to the English law, the descent of property is in some cases governed by the state of the infant when born. If it be living, or so far alive that the slightest vital movements could be perceived, such as a quivering of the lips, or the twinkling of the eyelids, then, under such circumstances, the husband would become entitled (by what is termed "the tangent by the courtesy of England") to the property. But if the infant be dead, then the right of inheritance passes in the line of consanguinity. A case illustrative of the above remarks occurred to Dr. Denman. (*Vide Beck, and Dr. Paris and Fonblanque.*)

Before the operation for the induction of premature labour is performed, the obstetrician should have fully acquainted himself with the relative measurements of the head of the infant and the pelvic space through which it has to pass. It is true, that there is

some variation in the size of the head; but these are exceptions, and the computation must be made on the average size. (See Table, p. 313.) The development of the infant's head continues to increase during its sojourn in the uterus; and, therefore, the labour should be ended as near as possible to the time we had fixed for its completion, as there is some doubt how soon effective uterine contraction may ensue after means have been employed to induce it. It would, therefore, be most desirable to commence the operation a few days before the computed period for the fulfilment of labour; especially so when some of the measures are adopted for this purpose.

So long as the membranes are entire, and the infant is unrestricted in its movement and floating in the liquor amnii, its life is comparatively safe; but, as soon as the water is discharged, it is subject to more hazard, from the compression it must necessarily bear, and especially so if the os uteri be not dilated. If this be true in ordinary labour, it is more decidedly so when it is artificially induced. Besides, there is no other means so effectual in distending the cervix, and in dilating the os uteri, as the membranous bag filled with the liquor amnii, which acts during each pain as a powerful wedge.

If the infant should happen to lie in a bad position, and require turning, either the old operation or the internal and external manipulation (Dr. Hicks's method) could be undertaken with more ease to the practitioner, and with greater safety to the infant.

On these grounds, then, it is of the greatest importance, when labour is artificially brought on, that the membranes should, if possible, be kept entire; and, therefore, those means should be employed which are calculated to accomplish this object.

There are various measures proposed to induce premature labour, which I shall very briefly mention. Stimulant injections thrown into the rectum, and abdominal frictions, and the application of a firm bandage round the abdomen, etc., ought only to be considered as aiding others.

Secale cornutum, in repeated doses, has been prescribed; but, from its well-known poisonous effects on the infant, it ought never to be employed in these cases.

The old, and perhaps the most common method of puncturing the membranes, is certain in its effects, although some days frequently elapse before labour ensues. Although I have formerly frequently adopted this plan, yet it is objectionable, on account of depriving the infant of the protective influence of the amnion fluid, etc. To partly obviate this evil, it has been proposed to carry an instrument through the os uteri and upwards between the uterus and the membranes, before piercing them.

Dr. Hamilton passed his finger through the os and upwards between the membranes and the uterus, and then round so as to detach them; and had the utmost confidence in it. His success was great. "Of forty-six infants thus prematurely brought into the world, forty-two were born alive." Although this method is safer than the older for the infant, several days sometimes elapse before uterine contraction is excited.

The vaginal douche has the confidence of many obstetricians. It consists of a forcible and continuous stream of water, sometimes warm and some-

times cold, being directed against the os uteri, so as to wash out the mucous plug. Although this is comparatively a safe measure, it is not always certain in its effects, and is also somewhat slow in acting.

The uterine douche, or injecting water into the uterine cavity by means of a syringe and an elastic tube passed between the membranes and uterus, has the approval of some practitioners. A considerable quantity of fluid has been thrown up by some; but this is a most hazardous experiment. Others have only injected three or four ounces. The risk of separating the placenta and throwing air into the uterine vessels renders the uterine douche rather objectionable.

Mechanical dilatation of the os by expanding instruments has been recommended; but such a plan ought never to be done; it is attended with great hazard.

Sponges, prepared so as to easily pass through the os, and left to expand, are comparatively safe, and may sometimes be employed as preparative measures. Distending the vagina with sponge-plugs, or by the introduction of a bladder which is afterwards filled by a syringe with water. One formed of caoutchouc is better adapted for the purpose. These latter methods are useful, precursory to other plans.

Elastic bags of various sizes have been contrived by Dr. Barnes, which are to be distended with water when they have been passed through the os uteri. As dilators, these contrivances are both safer and more efficacious.

The attempts to dilate the os uteri should be both gentle and gradual, and made to resemble as nearly as possible the method Nature pursues in opening this part. Forcible dilatation, without preparation, is at all times most mischievous. In cases of labour in which the hand has to be introduced through the os uteri, this operation ought not to be undertaken until this part (the os) becomes dilatible. So, in the operation of the induction of premature labour, our efforts ought to be directed to attain, if possible, this state.

In December 1844, I proposed galvanism as an important means of arresting uterine hemorrhage, and I also at the same time recommended this agency for the induction of premature labour; and my opinion still remains the same. If, however, galvanism is not used to excite uterine action *de novo* in these cases, its employment will be found most advantageous when uterine contraction does not easily or vigorously respond to the employment of some of the other measures. (*Provincial Medical and Surgical Journal*, Dec. 1844.)

Whatever plan is adopted, we should never forget what has been before said as to the necessity of having the parturient process completed as nearly as possible within the period of pregnancy fixed for its accomplishment.

TEST FOR COFFEE. There is probably no reader of the *Chemical News* who is not familiar with the test for the detection of chicory in coffee just published by M. Coulier; and I only quote it for the sake of the explanation he gives. Coffee, we all know, swims on water, while chicory sinks. The reason for this, says M. Coulier, is, that in the roasting of coffee the berry becomes distended, so to say, with carbonic acid, while in the roasting of chicory no gas is disengaged. (*Chemical News*.)

Original Communications.

CASE OF TETANUS IN AN INSANE PATIENT.

By J. GILCHRIST, M.D., Medical Superintendent
Crichton Royal Institution, Dumfries.

THE patient was a female, aged 74, well educated, respectably connected, and in comfortable circumstances. She is stated to have been insane for a month previous to admission; but it is also recorded that peculiarities were observable for some months. She was admitted on Dec. 22nd, 1864, and died on January 13th, 1865, having thus been three weeks resident.

On admission, she laboured under a mixed form of insanity, the characteristics of which were excitement, restlessness, vigilance, and abstinence, associated with delusions of a depressing nature. From the persistence of these conditions for some time previous to admission, the patient had become considerably exhausted, so much so, indeed—considering age, etc.—as to render the prognosis decidedly unfavourable. The usual treatment in such a case was followed—rest, sedatives, nutrients, stimulants, etc. By the end of the first week she had considerably improved. In a few days more, improvement had so far progressed as to allow of her associating with her companions in the common sitting-room. The excitement had disappeared; sleep had returned; she was taking the full ordinary diet, with the addition of beer-tea, milk, and wine daily. Her appearance had greatly improved. The only indication of her unsound condition remaining, being a tendency to revert to her delusions when left alone.

On January 3rd—the twelfth day after admission—her appearance struck me as unsatisfactory, and she was ordered to bed. It was then discovered that the right foot was swollen, and the cause was ascertained to be gangrene of the great toe. A corn which had existed on the first joint of the little toe was also in a state of slough. This had been previously noticed by the attendant, who thought it of no importance.

The patient was now kept in bed. Poulitices, etc., were applied, and nutrients and stimulants increased. For the next nine days, she was in every respect satisfactory, with two exceptions. She was sleeping well, feeling comfortable, taking food abundantly, and expressing herself rationally. The two exceptions were—the entire absence of reactive inflammation round the margin of the slough, and an unsatisfactory condition of the pulse, which, during the whole period of improvement, was slightly accelerated, and had a peculiar thrill.

On January 12th, the attendant went to give the patient her supper at 10 P.M., when she complained that she was unable to open her jaws. I was immediately sent for; but the spasm had considerably relaxed on my arrival. The nature of the disease; its probable cause; the condition of the toe; and the unsatisfactory state of the patient, were immediately appreciated; and, of course, an unfavourable result was anticipated. Attacks followed at 3, 8, and 10 A.M., at 12 noon, and at 1 P.M. The last terminated in death.

The spasms, excepting the two last, were not severe, and involved only the muscles of the neck, and latterly those of the chest.

Pain was never complained of, except in the jaws and neck during the spasms, and especially in the left side, immediately under the mamma. The sternal pain, so often noticed in this disease, did not exist.

The circulation was not much impeded, except during the two last paroxysms. The patient, however, evidently died asphyxiated, as the heart's action was vigorous only a few minutes before death.

The only treatment adopted was the administration of enemata and stimulants. The results of an enema proved the evacuations to be normal; and, from the rapid progress of the case, stimulants could not be administered to any extent.

The cause of the gangrene is still an undecided point; that is, whether it was the ordinary gangræna senilis, or specially induced by the exhausted condition of the patient, or by exposure during the night when excited and sleepless. Her age points to the first as the probable cause. The slough was confined to the lower surfaces and about one-half of the inner side of the toe. It was dry in its character, and might possibly have been unobserved by the attendant.

It is, at the same time, however, to be kept in view that, especially during the first week of the patient's residence, she was restless, and occasionally out of bed, although the night-book does not show this to any great extent, and the night-watch had special instructions to visit her hourly. It remains a question, therefore, whether such exposure, if it existed, was the cause, as is often asserted, of this formidable though happily rare disease.

RETROSPECTIVE NOTES ON OUT-PATIENT PRACTICE.

By C. M. DURRANT, M.D., Physician to the East Suffolk and Ipswich Hospital.

[Continued from page 247.]

SKIN-DISEASES.

1. *Eczema*. Among the affections of the skin which have presented to our notice in the last two years, eczema has very greatly preponderated in point of frequency. It has obtained largely among infants, and in the adult it has shown itself chiefly in the acute and chronic varieties of eczema simplex, eczema rubrum, and eczema impetiginodes. Many of the cases have been exceedingly obstinate, and the majority have been intimately associated with irritation of the gastric mucous membrane.

In the treatment of eczema as it has obtained among our patients, three chief indications have appeared to me to be essentially necessary to be observed in its management.

a. In reference to *Diet*, the mildest food, limited to broth, with vegetables, fish, and farinaceous articles, should only be allowed at first. Without this precaution, the stomach has invariably become the painful seat of severe irritative dyspepsia or chronic gastritis, so soon as the eruption has been checked by local treatment. On no account must malt liquor be allowed; but, if a stimulant be needed, claret or sherry and water may be taken.

b. *Medicines*. I have found no combinations answer so well as the citrate and chlorate of potash mixture, with the aromatic spirit of ammonia. In chronic and anæmic cases, the liquor potassæ arsenitis may be advantageously added to this mixture; but in the forms of eczema, as it obtains in this locality, I have not found that arsenical preparations, as a rule, afford the benefit, or, indeed, that they can be borne in the general manner in which their adoption is so strongly advised by many writers upon skin-diseases.

Cod-liver oil is a valuable tonic in chronic eczema; and, if a syphilitic taint be suspected, the iodide of potassium, with the bichloride of mercury, should be had recourse to.

c. *Topical Treatment*. Eczema is one of the diseases of the skin in which local applications act much more favourably when used in conjunction with the constitutional treatment recommended above.

If the form of the eruption be acute, the mildest and most soothing applications should be at first selected. Of these, I have found none better than simple warm water, applied by means of a rag, and covered with oiled silk. If this fail, a weak solution of the acetate of lead, with glycerine, will often prove of great comfort and advantage.

If the skin be dry, and the eruption assume a more chronic form, I have often found the best result from the application, night and morning, of ointment of ammoniated mercury. Again, if this fail, the zinc ointment, or the ointment of iodide of sulphur, should be tried. A solution of the nitrate of silver, in the proportion of five to ten grains to the ounce of distilled water, will sometimes effect a speedy cure, after the failure of all the above preparations.

As already stated, however, eczema is often a very troublesome complaint; and the frequent change of local treatment, with the possession of an extensive and varied formula for its relief, will be found to be of the greatest assistance in its successful management.

2. *Psoriasis and Lepra*. I have coupled the notice of these two forms of squamous skin-affections together, inasmuch as the treatment for each is similar; and the consideration of them as modifications of one and the same disease is a view still held by very many. There is, however, a specific diagnosis given in books; viz., that in lepra the patches are circular, and depressed in the centre, with elevated margins; while in psoriasis the eruption is irregular in form, and without the central depression. Next to eczema, these squamous forms of disease have occurred most frequently; and I, therefore, consider them in succession, irrespective of the order and classification in which they are generally arranged.

In the treatment of psoriasis or lepra, an unstimulating but moderately nutritious diet will be the best, scrupulously forbidding malt liquor in any shape. In reference to constitutional treatment, arsenic is the sheet-anchor; and, if the stomach be irritable and disordered, this medicine may be advantageously combined with an alkali. It should be administered half an hour after the three principal meals. If there be coexisting anæmia, with debility, the addition of the iron wine will be useful.

I have not seen benefit from dulcamara; but it forms a good vehicle for large doses of the liquor potassæ, if the arsenical preparations be not well borne.

In some obstinate forms of local psoriasis, mercury, carried to the extent of slight pyalism, has cured the disease; and this in cases of females, in which no syphilitic taint could be detected.

In reference to local treatment, it will be well to commence, when practicable, with a few simple or alkaline warm baths. After this, I have seen no formula act so well, on the whole, as the following, and which I first saw used by my late colleague, Dr. Beek.

℞ Picis liquidæ, sulphuris, axungiæ, aa partes æquales.

This is to be kept uninterruptedly applied to the parts affected for a week, and in severe and obstinate cases for a fortnight at a time, without being washed off. The patient, if within a hospital, should remain in bed during the application.

At the end of a week or fortnight, the skin should be thoroughly cleansed by means of a warm bath; and, if necessary, the same treatment resumed for another fortnight. As a rule, two or three applications, conducted in this manner, will generally cure

the disease. The arsenic mixture should, of course, be given at the same time.

If this remedy fail, the iodide of sulphur, or white precipitate ointments, may be tried; or, if the disease be limited in extent, repeated blistering will sometimes cure an inveterate patch.

3. *Prurigo*. This eruption has been very troublesome in two or three cases. The varieties in which it has exhibited the greatest obstinacy have been the *prurigo senilis* in both sexes, and *prurigo pudendi* in the female.

In the milder forms of the affection, a light unstimulating diet, with simple or alkaline warm baths, and the steady use of saline purgatives, will often suffice to cure the disease.

To allay the itching, the affected parts should be sponged with vinegar twice a day, which must be allowed to dry on. If this fail, the dilute solution of subacetate of lead, with glycerine, may be used; and, if the disease still resist, the ointment of ammoniated mercury or ointment of nitrate of mercury may be smeared upon the part night and morning.

In the severe forms above mentioned, our best endeavours will be sometimes baffled for a considerable time. In these cases, I have found the preparations of arsenic and cod-liver oil, with small doses of the bichloride of mercury at night, decidedly useful. The latter preparation, used as a lotion, in the proportion of one or two grains to the ounce of equal parts of glycerine and water, will sometimes allay the intolerable itching.

The late Dr. Craigie recommended a strong ointment of the sulphuret of potassium in this and in some other chronic skin-affections attended with much itching.

4. *Urticaria*. This affection is in general of so mild a character, and so easily managed by constitutional treatment alone, that I should scarcely have made a note upon it, had not two severe cases presented themselves. Both of these were benefited in a very marked manner by venesection; and the recovery was speedy and complete.

5. *Herpes*. The only forms of this eruption which have presented among our out-patients have been herpes phlyctenodes, herpes labialis, and herpes zoster. All recovered quickly under a cooling diet and regimen, with salines and mild aperients.

Herpes zoster, when it occurs in elderly persons, sometimes gives rise to much alarm and distress, particularly if it leave behind it the severe neuralgic pains which often attend the disappearance of this form of the disease, in those advanced in years. The best remedy for this latter complication is, I believe, quinine in full doses, and the local application of a very strong solution of opium, to which, if necessary, chloroform may be added.

6. *Erythema*. This affection, in the form of erythema nodosum, is a very common result of the debility and exhaustion under which out-patients so frequently labour. When it occurs, however, as it sometimes does, as a consequence of rheumatic cardiac disease, it must be regarded as an unfavourable complication; and a very guarded prognosis in these cases should be given. No remedy cures this disorder so rapidly as quinine, provided that the stomach be in a state to assimilate it. When the spots are very painful, the legs should be rested in the horizontal posture, and the swelling kept moist by linen soaked in warm water, and covered with oiled silk. If the patient cannot rest, painting the erythematous patch daily with the tincture of the sesquichloride of iron may be adopted with advantage.

7. *Impetigo*. We have had examples both of *impetigo figurata* and of *impetigo sparsa* in the past two years.

The disease may be very severe in its acute form, and very obstinate and unmanageable in its chronic condition. When it occurs as an acute affection in an adult not weakened by previous illness, I should have no hesitation in advising venesection; and its adoption will, I think, be attended with decided benefit. In addition to this, the steady use of saline purgatives, with a mixture of the citrate and nitrate of potash, with small doses of the tincture of colchicum, will be useful. Externally, poultices or warm bran fomentations, and warm baths, with rest, will be proper.

The diet, as in most skin-diseases, must be mild and unstimulating; and wine or beer, as a rule, prohibited. If either be necessary, the former should alone be allowed.

If the disease occur on the scalp, it will be useless to attempt to cure it without having the hair previously cut quite close, and the scalp well poulticed to remove incrustations.

In the more chronic forms of the complaint, liquor potassæ, in full doses (twenty minims to one drachm three times a day, freely diluted), may be given; or, if this fail, arsenic will be the proper remedy. After removing the crusts by poulticing, the ointment of oxide of zinc or of subacetate of lead, used separately or in combination, will sometimes effect a cure.

As a rule, I believe that a better result will be seen to follow the persevering use of soothing measures applied locally, in conjunction with constitutional treatment, than by resorting too early to a more stimulating and exciting method of cure.

8. *Acne*. Two chronic cases of the indurated form of this affection have presented for relief.

Attention to the digestive organs, with the compound rhubarb pill at bed-time, and iodide of sulphur ointment smeared upon the face at night, acted very beneficially.

In some cases, a spirit lotion, with the addition of two grains of the bichloride of mercury to each ounce, will have a good effect.

Change of air, and the adopting of a different mode of living, will sometimes succeed in removing the eruption after the failure of a variety of local applications.

9. *Rupia*. Only one well marked example of *rupia prominens* has shewn itself among the out-patients in the two years.

The treatment consisted of a persevering use of poultices, and an alkaline mixture, with the liquor potassæ arsenitis internally. Under this plan, the case, which was a rather severe one, from the number and succession of the blebs and oyster-shell scabs, recovered satisfactorily.

10. *Alopecia*, or *Tinea Decalvans*. This parasitic affection is not an uncommon out-patient's malady. We have had it present both in children and in adults.

The patches from which the hair has fallen are generally circular or oval in shape and vary in size. In the case of an adult who some years ago came under my notice, the disease had entirely removed the hair from the scalp, eyebrows, pubes, and axillæ.

I have seen the iodide of sulphur ointment cure the disease; or, in the event of this failing, creasote ointment, or either of the following lotions, may be tried; the object being, of course, to destroy the parasite.

℞ Sodæ hyposulphitis ʒij; acidi aceticæ ʒj; aq. rosæ ʒviij. M. Or

℞ Hydrargyri bichloridi gr. xij; tincture canthar. ʒj; aquæ rosæ ʒv. M.

The denuded patches must be well sponged with these lotions night and morning. Painting the spots

with the acetum cantharidis may be necessary in intractable cases.

11. *Syphilitic Eruptions.* Cutaneous eruptions originating from this specific cause are very rife among the class of out-patients who frequent our hospitals. Almost every variety of skin-disease is represented under these circumstances. The majority, however, as a rule, yield readily to the combined exhibition of mild mercurials, with the iodide of potassium.

I have generally found small doses of the bichloride of mercury, given night and morning, to be the best form for its administration; and it is generally admitted that the iodide of potassium acts more certainly when given with this medicine than when a course of each remedy is prescribed separately.

An important point for consideration is the formation of a correct diagnosis; and, in addition to the colour of the eruption, we shall often find useful diagnostic auxiliaries in the condition of the fances and the periosteal covering of the tibiae.

In some questionable cases, an experimental trial of the above medicines will serve to clear up the doubt.

[To be continued.]

Reviews and Notices.

A TREATISE ON MILITARY SURGERY AND HYGIENE. By FRANK HASTINGS HAMILTON, M.D., late Lieutenant-Colonel, Medical Inspector U.S.A.: Professor of Military Surgery and Hygiene, and of Fractures and Dislocations, in Bellevue Medical College; etc. Illustrated with 127 Engravings. Pp. 648. New York, London, etc.: 1865.

THIS book has grown out of a small treatise which Dr. HAMILTON published at the commencement of the present war, for the guidance of those who were for the first time acting as army surgeons. The large stores of military surgical experience which have since accumulated are not yet entirely at the disposal of the profession; but sufficient information has been derived by the author from the communications in the medical journals, and from several friends, to enable him to bring forth a new work, and to discuss fully numerous questions of interest.

In the first or introductory chapter, Dr. Hamilton expresses very clearly the affinities and the differences of military and civil practice. "Military and naval surgery" (he says) "is not a new and distinct science; but only the science of medicine in its largest sense, with a special application." The principles are the same: their fundamental laws are nearly identical, but they differ occasionally in their subordinate rules, in the means used to obtain the same ends, and especially in the relative frequency of certain accidents and diseases. Having illustrated these points of difference, the author refers to the necessary requirements of the military surgeon, and remarks on the manner in which the science of military medicine has advanced commensurately with the science of warfare. We find also some practical remarks on the means of conveying wounded soldiers from the field adopted in various countries, and an account of the system followed in the Federal army.

"The value of medical services to an army" (Dr. Hamilton truly says) "in a strategic, economical, and humane point of view, is indisputable." But, a

few pages further on, we find evidence that this principle has not been thoroughly recognised in America, any more than in this country. On this point the author has some remarks, which are peculiarly interesting at the present moment.

By an Act of Congress dated February 11, 1847, it was declared that

"The rank of officers of the Medical Department of the Army shall be arranged upon the same basis which at present determines the amount of their pay and emoluments: provided, that medical officers shall not, in virtue of such rank, be entitled to command in the line or other staff departments of the army."

The object of this was to raise the medical officers from a position of subordination in which they had been liable to annoyances and even to insults from inferior officers, "and to secure for them those courtesies and that respect which they had a right to claim." But, although the great body of the army and navy officers have, according to Dr. Hamilton, recognised the obligations of the Act of Congress, some have persistently refused to do so, and "have habitually and openly violated both its spirit and its letter."

The American army surgeon, like the British, is told, as a reason for depriving him of his proper privileges, that he is a non-combatant, "and that to combatants alone, upon whom rest the hazards and responsibilities of war, rightly belong its honours." Dr. Hamilton very justly utterly denies the correctness of this argument, and demonstrates the absurdity of the notion prevalent in some quarters that, while the officers of the subsistence department are to be treated as combatants, the surgeons are non-combatants.

"If exposure to hardship and danger is to be the ground upon which rank is to be conceded to officers of the army or of the navy, we think the claims of the medical officers may be easily determined. The medical officers are exposed to the same hardships on the march or in cantonments as the officers of the line; and while the latter have to incur the hazards of battle only occasionally, perhaps but once during a campaign, the former may be said to be doing battle daily, being constantly subjected to the dangers of pestilence by their exposure to the contagions and infections of crowded and unwholesome hospitals. We have not the statistics before us upon which to base a positive statement; but we entertain little doubt that, were the facts known, it would be found that, in proportion to the number employed in any campaign, the number of deaths or of invalided in the medical staff, by the ordinary casualties and exposures of the service, is greater than in any other department.

"But, as compared with the quartermaster or subsistence officers, the hazards of the medical officers are undeniably greater. The services of the first are never required upon the field; whilst the surgeons are expected to accompany their respective regiments until the action commences—and then only to retire to some position of comparative, but not absolute, safety. The instances upon record in which medical officers have been wounded and killed upon the field of battle, when in discharge of their appropriate duties, are numerous." (Pp. 30-1.)

Dr. Hamilton brings forward several illustrations of this fact. The first is a remarkable one related by Dr. Tripler. "In the brilliant campaign of General Scott in Mexico, the medical staff was the

only one that had an officer killed or wounded." The author also refers to the case of Assistant-Surgeon O'Leary, killed at the siege of Sebastopol; to the dangers to which the illustrious Larrey was exposed in the field of battle; to the instances of heroism and self-devotion shown by medical men in times of disease and danger; and says:

"We challenge any man to-day to point us to an educated physician who has fled at the approach of pestilence, or who has hesitated to enter the trenches, or to face the batteries, if required to do so in the performance of his legitimate duties. Even when the strict letter of his instructions forbade his exposure, the medical officer has seldom been backward to accept any duty which the exigency seemed to impose upon him." (P. 34.)

Thus, in 1847, fell in battle a pupil of Dr. Hamilton, Assistant-Surgeon G. W. Roberts, while leading a column after all the officers of the line competent to command it had fallen; and, during the present war, besides the cases in which the surgeons of the Federal army have yielded themselves into the hands of the enemy when they believed that the condition of the sick and wounded soldiers demanded their care, and while some of them have subsequently been confined in prisons, and have died, or have returned broken down in health, examples have not been wanting—we may say they are numerous—in which army surgeons have been wounded and killed on the battlefield in the performance of their appropriate duties. Dr. Hamilton gives, at pages 35 and 639, a list of seventeen such cases. Here are some of the notes appended to the names. "Received a wound at the battle of Gettysburg, on account of which he has been discharged from the service"; "Discharged on account of wounds received at the battle of Chancellorsville"; "Severely wounded in the leg"; "Wounded by fragments of shells"; "Severely wounded in the back"; "Received a ball in his leg"; "Wounded by a ball which passed through the popliteal space"; "Shot through the abdomen and subsequently died"; "Shot through the head and killed instantly"; "Killed by a sharpshooter while riding along the skirmish line in company with the general"; "Killed in a night attack made by the enemy"; "Killed at the battle of Shiloh"; etc. In each case, the name of the officer, his regiment, and the circumstances in which he was wounded or killed, are given.

As a fitting comment on such cases, in their bearing on the question whether army medical officers are combatants or not, Dr. Hamilton quotes the words of Lord Dalhousie, in a memoir upon the medical service appended to the Report of the Parliamentary Committee. While the American army surgeons, on the one hand, thus bring forward a British authority to support their claims, our army surgeons will no less find material in support of their just demands in the facts placed on record by Dr. Hamilton.

The question whether the so-called non-combatant officers are entitled to be members of courts-martial has been agitated in America; and, in the navy, it appears, that the right has been conceded—but not in the army. An order issued by the Secretary of the Navy in 1861 was as follows.

"Whenever any officer of the corps of surgeons, paymasters, or engineers, is arraigned for trial before a Court of Inquiry or Court-Martial, the Court shall

consist in part of officers of the corps to which the accused belongs."

Why, Dr. Hamilton asks, should not a similar rule be applied to the army?

As to relative rank, the following is the present position of army medical officers in America, as established by Act of Congress. The Surgeon-General is a Brigadier-General; the Assistant-Surgeon-General is Colonel; the Medical Inspector-General is also Colonel; and the sixteen Medical Inspectors are Lieutenant-Colonels. With these exceptions, no other medical officers, not even the Medical Inspectors of Departments, have higher rank than that of Major; although, in 1862, commissaries, quartermasters, etc., serving on the staffs of corps commanders, were made Lieutenant-Colonels. In America, as in some other foreign countries, the medical officer is entitled to append to his name his relative rank.

Dr. Hamilton, after referring to the circumstances already mentioned, and to the fact that "in the medical staff there is no such thing as promotion for good conduct or for the performance of signal services", and saying that even *brevet* has been denied, though often recommended, asks on what test of respectability or of social, moral, or intellectual standing, these and other invidious distinctions are made? He asserts, and we have no doubt truly, that the medical officers of the army are at least the equals of the officers of the same rank in other departments. As to the volunteer surgeons of the Federal service, he makes out a still stronger case in their favour; for he points out that "they are the only commissioned officers in the volunteer army who have had any previous education or training to the peculiar and respective duties which they have been called upon to perform."

The question as to the amount of *authority* which should be vested in army medical officers is also noticed by Dr. Hamilton; and from him we learn that the same objection is urged in America as has been urged here. It is alleged "that to divide or distribute authority is to destroy the unity and power of the army, and that it is essentially destructive of all military discipline." But, says Dr. Tripler, an authority of some eminence among American army surgeons, the engineers cannot command out of their corps, but they are not subject to the orders of their juniors in the line; and the result of this is, that this corps, the only one which has an analogy with the medical as to scientific acquirement, special function, peculiar administration, and claims to independent action, is one of which the superior is not to be found.

"We conclude, then" (says Dr. Hamilton) "that to the medical officers ought to be intrusted the complete control of the medical department, because upon the preservation of the health of the troops depends, in a great measure, the success of every expedition, because no others than medical men are, by their education and habits, qualified to perform this duty; because no one else is competent to decide upon the proper location of a hospital, its construction, ventilation, or general arrangement; no one else can determine what is necessary for the sick in the way of diet, clothing, medicine, etc.; no one else knows when rooms are over-crowded and in danger of becoming pestilential, or when patients can be removed with safety. In short, because officers of

the executive department, from the entirely distinct nature of their pursuits, whatever they may believe to the contrary, do actually know as little of hygiene, medicine, and surgery, as they do of engineering. Because, moreover, medical men are supposed to be qualified, they are appointed for the express purpose; and because, without authority, they are unable to carry out their own views, and it is impossible, therefore, that the public service can receive the full benefit of their ability." (Pp. 41-2.)

We have thus dwelt at some length on Dr. Hamilton's remarks on the status of the army surgeon, on account of the interest with which this subject has been and still is regarded in this country; and we have shown from his book how in America the same just demands are made as among ourselves. Assuring him, as we believe we may, that he has the hearty approbation and warm sympathies of the profession in Great Britain, in his endeavours to establish and defend the privileges of the American army medical officers, we must now quit this subject, and proceed to other matters.

The subjects of the remaining chapters of the books are the following: 2. Examination of Recruits; 3. General Hygiene of Troops; 4. Bivouac, the Accommodation of Troops in Tents, Barracks, Billets, Huts, etc.; 5. Hospitals; 6. Preparations for the Field; 7. Hygienic Management of Troops upon the March; 8. Conveyance of Sick and Wounded Soldiers; 9. Gunshot Wounds; 10-12. Gunshot Wounds of the Head, Face, and Neck, and Thorax; 13. Punctured and Incised Wounds of the Thorax; 14. Gunshot Wounds of the Abdomen; 15. Punctured and Incised Wounds of the Abdomen; 16. Gunshot Wounds of the Male Organs of Generation; 17. Gunshot Fractures; 18. Amputations; 19. Exsections; 20. Arrow-wounds; 21. Traumatic Gangrene; 22. Hospital Gangrene; 23. Dry Gangrene; 24. Tetanus; 25. Scorbuts; 26. The Employment of Anæsthetics in Major Amputations and in other Severe Surgical Operations after Gunshot Injuries. There is also an Appendix on several interesting matters.

This list is a comprehensive one, including not only the consideration of subjects directly medical, but also those having a bearing on the preservation of health. *Prima facie*, therefore, Dr. Hamilton has made his book a very complete one. We will notice his opinions on a few points.

Food. In the section on Food in the second chapter, the author expresses a strong opinion against the use of alcoholic drinks in the army, as being unnecessary and injurious. As to food, the supply authorised for the use of the Federal army has been very liberal; but "it is nevertheless true that our soldiers have not always been well fed, even when campaigning in those parts of the country which have abounded with vegetables, grain, and animals suitable for food." As a result of this, and especially of the deficiency of fresh vegetables, scurvy has prevailed to a great extent; so much so, that the author believes that 20,000 men might have been saved to General McClellan's army in one campaign if the men had been furnished with a reasonable amount of fresh vegetables. He attributes the defective supply to want of knowledge on the part both of the commanding officers of regiments and of their subordinates, who do not understand that the prolonged deprivation of vegetables most seriously

impairs the health of the men. He also refers to some curious instances of mismanagement as causes of the non-supply of vegetables. In the army of the Cumberland, the officers *believed* that the soldiers had received a full supply of vegetables, whereas they had had but three full rations in twelve months.

"The explanation of this extraordinary fact is, that during nearly all this time fresh potatoes, and occasionally other vegetables, were received and issued; but of one hundred barrels issued by the Chief Commissary, at least twenty-five went to the staff officers' families and servants at head-quarters, and to the post, including often citizens and hospitals; of the seventy-five remaining for distribution to the Corps Commissaries, twenty-five were barrels disappeared again with the officers and their families; a third distribution to the Division Commissaries blotted out another twenty-five barrels, and a fourth to the Brigade Commissaries disposed of the remainder in a like manner, so that the Regimental Commissary had none; and it is here that the inquiry must always be made, or with the soldier himself, if an inspector desires to know how the troops are fed." (Pp. 82-3.)

This state of things was, however, remedied on the representation of the medical officers. A proper supply of good vegetables was sent and distributed; in consequence, the cases of scurvy diminished, and wounds received in battle healed kindly and were followed by fewer accidents than before.

Hospitals. In the construction of hospitals, Dr. Hamilton prefers the radiate form, as being most capable of free ventilation and convenient of administration. He is also convinced that all hospitals ought to be "one-story buildings, elevated three or four feet from the ground."

Arrow-wounds form rather an unusual subject for a surgical treatise; but the propriety of introducing some remarks on the subject in a book intended for those engaged in American warfare will be apparent. Dr. Hamilton has derived the principal part of his information on this subject from an instructive paper published in 1862 in the *American Journal of the Medical Sciences*, by Assistant-Surgeon J. H. Bill. The reader will find a description of the arrows used by the American Indians, the kind of wounds which they produce, and the means of removing them. This process is not always easy; for when the head is entirely buried, an attempt to pull it out by dragging by the shaft is apt to result only in leaving the head alone in the wound; sometimes the point of the arrow is lodged in a bone, even so strongly as to require much force, applied by tooth-forceps or by some such means, for removal; while, in other cases, again, the head of the arrow on striking a bone may bend, and pass partially round the bone between it and the periosteum.

Hospital Gangrene. The chapter on this subject is written by Dr. F. H. Hamilton, jun. The disease has been very prevalent in the hospitals of the Federal army. In the treatment, the author recommends the removal to a distance, or still better the destruction by burning, of all lint, bandages, and other dressings, taken from a suppurating surface. The general treatment should be sustaining; consisting in general of wine, porter, and other stimulants, together with iron, quinine, and beef-tea. As a local remedy, Dr. Hamilton, jun., gives the preference to bromine. He says:

"We are indebted to Dr. M. Goldsmith, Surg.

U.S.V., for the introduction of this valuable agent. In order to obtain the full and complete effects of bromine, it should be applied carefully and thoroughly. The following practical hints, suggested by Dr. Goldsmith, most of which have been confirmed by my own experience, should be observed in the application of this agent. 1. If the operation promises to be a painful and tedious one, Dr. Goldsmith advises that the patient be rendered insensible by the use of an anæsthetic. This I consider of doubtful propriety, inasmuch as I regard the depressing influence of chloroform as a predisposing cause of the disease. 2. The wound, having been carefully cleansed by thorough sponging with warm water and soap, should be freed from all dead and gangrenous tissue by means of a scalpel or scissors, aided by the forceps. The healthy tissue should be denuded as far as possible. 3. The surface to be treated should now be thoroughly freed from moisture. This is most readily done with a swab of lint on the end of a probe, with which the surface is carefully dried. Do not omit to penetrate the pouches and recesses. 4. If the pure bromine be used, a small glass pipette should be introduced into the bottle containing the liquid, and then, being carried to the surface to be cauterised, thoroughly applied to every part. Cavities may be reached by means of small portions of lint dipped in the bromine, and then carried by means of an eyed probe, or a pair of forceps, into the desired positions. 5. It is frequently beneficial to paint the surrounding tissues to the extent of an inch, perhaps, with a solution of the bromine; using a drachm of the bromine in four ounces of water. 6. Immediately after the application of the bromine an emollient poultice should be applied. This tends to allay any undue irritation, and favours the speedy evolution of the slough. There are three different preparations of bromine which have been employed. Dr. Goldsmith first employed a solution of the bromide of potassium and bromine, or the compound solution. After using this for some time, he at length resorted to the pure brominium, and very soon arrived at the conclusion that this was the only form in which it should be used. I have used both the compound solution and the pure bromine, and do not hesitate to express my preference for the latter article. I have also used a dilute solution of the pure bromine, in the proportion of a drachm to eight ounces of water, with great benefit, as a disinfectant and prophylactic dressing to be applied to unhealthy-looking wounds. After having carefully applied bromine to a case of gangrene, we find that the part smells perfectly sweet and clean. If there is any trace of the odour remaining, we may be sure that our application has not been thorough. The fumes of bromine, given off as a dense red vapour when a bottle of this liquid is unstoppered, furnish us with an invaluable diffusible deodoriser in wards where the emanations of a large number of suppurating wounds render the atmosphere fetid." (Pp. 577-8.)

Pernanganate of potass is also, says Dr. Hamilton, jun., scarcely inferior. Maunsell's solution of persulphate of iron is also very useful; and Dr. Hachenberg of the Federal army has recommended the use of spirits of turpentine. The author gives a statement of some observations made on the comparative effects of nitric acid and bromine. Of eighteen cases treated with nitric acid, the average duration was sixteen days; while of fourteen treated with bromine, the average duration was only 6.64 days.

Anæsthetics in Military Surgery. Dr. Hamilton arrives at the following conclusions on this subject.

"Anæsthetics are of inestimable value in their efforts as remedial agents; in their power to extinguish sensibility temporarily, especially during the performance of certain painful surgical operations; in the control which they exercise over muscular action, thus facilitating the reduction of dislocations; and in very many other ways. Anæsthetics, however, induce certain effects upon the system which tend to prevent union by the first intention; and consequently they must be regarded as, indirectly, causes of suppuration, pyæmia, secondary hæmorrhage, erysipelas, and hospital gangrene. Ether ought generally to be preferred to chloroform, as being less liable to destroy life immediately; but no anæsthetic ought to be employed when the system is greatly prostrated by disease, or by the shock of a recent injury or by loss of blood, unless the patient exhibits an unconquerable dread of the operation, or the operation is likely to prove exceedingly painful." (Pp. 621-2.)

Dr. Hamilton has evidently not a very favourable opinion of anæsthetics; but his views, the long experience on which they are founded, and his temperate manner of expressing them, are worthy of consideration, even though other surgical experience may not confirm him.

This work of Dr. Hamilton is one of great merit, and in our opinion admirably calculated to fulfil its purpose—that of a guide to the American army surgeon. It is written in an easy, clear, and instructive style; and contains a great deal of sound judicious instruction. As has already been shewn, Dr. Hamilton has not yet had at his disposal all the stores of information in military surgery that have been accumulating in America during the last four years; but he has made very good use of what he has been able to collect. If, when the war shall have terminated, such men as Dr. Hamilton are entrusted with the task of utilising the medical reports of the army, military surgeons may hope for a most valuable addition to the literature of their science.

ON THE INHALATION OF GASES AND MEDICATED VAPOURS. By W. ABBOTTS SMITH, M.D. London: 1865.

The contents of this pamphlet were originally published in the *Medical Mirror*. In it the author gives an historical summary of the subject; and tells of the principal uses of inhalation.

ON PRIMARY CANCER OF THE BRAIN. By G. M. BACON, M.D. London: 1865.

In this pamphlet, Dr. BACON gives an account of his investigations into London hospital records to determine the frequency of the occurrence of cancer in the brain. He gives the details of twenty-one cases of the disease. The pamphlet contains a very useful summary—not elsewhere to be found—of the history of this disease, as exemplified by the cases detailed.

ST. MARY'S HOSPITAL. The Prince of Wales has kindly promised to lay the first stone of the new building which the governors have decided to add to St. Mary's Hospital, in order to meet the increasing wants of the neighbourhood. The Prince will perform the ceremony after his return from Dublin. The foundation-stone of St. Mary's Hospital was laid by the late Prince Consort, in 1841.

Progress of Medical Science.

MEDICINE.

HOT WATER AS A REMEDY FOR PROFUSE PERSPIRATION. Dr. Druitt calls the attention of the profession to "the use of hot water as a remedy for profuse perspiration." The water must be applied as hot as the patient can bear it and be continued until the parts heated are "hot, red, and tingling with heat." If cold water be used, the part remains cool for some time and then becomes gradually warm or glowing; if tepid, it is usually made unpleasantly chilly and flabby; if warm, it is left perspiring; if hot, it is left hot, red, and dry. The cases in which he has recommended it with benefit are—first, those of general tendency to perspire to a distressing degree in hot weather, the patient being in good health. The next class of cases are those in which, with or without tendency to perspire over the body generally, but most probably without, there is a tendency to distressing perspiration of some particular part; as the axillæ, hands, feet, etc. Thirdly, there are the cases of true hectic; diurnal shiverings, followed by heat, and drenching perspiration of an earthy, sickly odour, and depending (as we suppose) on absorption of decaying pus from some internal organ, probably lung, etc. But there is a fourth variety—the ordinary night sweat of the phthisical, not preceded by regular hectic paroxysm, but induced by all that relaxes, lessened by all that strengthens, and coming on when the patient falls asleep. For many of these cases the hot water gives relief, to a certain extent, especially if the perspiration begin, as it often does, on one special part of the body by preference, as the chest, hands, or feet. Whoever uses it must recollect that it is not warm, but hot water, just below scalding point, that is to be employed. (*Medical Times and Gazette*.)

HYPODERMIC MEDICATION. Under this title Dr. McGugin of the University of Iowa gives some interesting cases of the effects of subcutaneous injection of morphia. His list, he says, embraces but a few of all the cases, in all of which the results were nearly as prompt and efficient. 1. In the summer of 1862, a soldier was admitted into hospital who had been wounded in the foot by a rifle-ball. The wound was still discharging, and in a few days several small spiculae were removed. The wound healed, and he was able to walk with trifling difficulty. In jumping, however, one day, he again injured his foot, which inflamed so much as to confine him to his ward and bed. Trismus appeared during the third night, and by morning the jaws were so tightly closed that speech and deglutition were impossible, and the respiration very laborious. The index finger of the right hand was contracted, and there was some disposition to opisthotonos. Chloroform by inhalation, and endermically applied along the spine, with enemata of tincture of opium, had been the treatment. Very soon afterwards Dr. McGugin saw him. A free incision into the old wound was followed by a discharge of pus, but with no apparent relief. By a small glass syringe, one-third of a grain of acetate of morphia in one drachm of distilled water was injected into the cellular tissue of the arm opposite the insertion of the deltoid muscle. In about half an hour there was some relaxation of the muscles of the jaws. Water was introduced, and a little swallowed with a painful effort. At the expiration of an hour more he swallowed with less difficulty; and in half an hour more,

making two hours from the first injection, as he did not seem to improve further, the same amount was injected into the other arm at the same point. In an hour from this second injection he slept soundly, and the respiration was much less difficult. This condition was maintained during the night. He was roused with some effort in the morning when he asked for water, which was the first word he uttered since the trismus was observed. There was some effort and also some pain in swallowing the water, nor could he turn his head to either side. He soon sank to sleep again, and slept as profoundly as before. He continued to sleep, at intervals, for two days, when the trismus had entirely disappeared, and the flexors of the index finger were relaxed. In a few days a spicula of bone was removed, after which the wound healed permanently. 2. In a case of delirium tremens in an habitual drunkard—a soldier, opiates given by the mouth failed to procure sleep. The hypodermic injection of one-third of a grain of acetate of morphia procured sleep; and a speedy recovery followed. 3. In the case of another soldier who was delirious, and in which nothing could be given, either by the mouth or by injection, which would have any effect in mitigating the symptoms, the hypodermic injection of morphia into the cellular tissue calmed the delirium in less than half an hour, and quiet repose followed. 4. A soldier whose vital power had been much expended by severe duty in the field, and an attack of camp-diarrhœa, was seized, since admission, with pneumonia, and sank rapidly. Two days before his death he was wild and frantic, requiring two, and often three nurses to confine him to his bed. His screams were loud, and he was resolutely determined not to take any medicine, nor would he swallow water or any other fluid. Acetate of morphia was injected in the dose of one-fourth of a grain; and in less than an hour he was fully conscious, and continued so until his death, which was easy and tranquil. 5. A washer-woman, aged 45, employed in the hospital, had eaten of fruit too freely, and was attacked with spasms of the diaphragm, stomach, and bowels. The gastric irritation was so great that small portions of morphia placed upon the tongue promptly induced emesis, and were thrown off as fast as given. The injection of acetate of morphia into the tissues of the arm was followed by relief in ten minutes; and in twenty minutes she was asleep, and arose next morning declaring herself "weak, but well." 6. A lady in this city had for some years been subject to frequent and severe attacks of facial neuralgia. Quinia and morphia and all other appropriate remedies had been resorted to, beside a *quantum sufficit* of potent nostrums, all of which were alike unsuccessful. The paroxysms returned every two weeks, and were more and more severe. Having been sent for in one of her alarming attacks, and finding that reason was suspended, Dr. McGugin at once introduced into the arm the salt of morphia; and in less than half an hour she was entirely relieved of her agonising sufferings, soon was asleep, and has not had a paroxysm since then, which was in May last. 7. Another lady of delicate frame suffered much after her confinement three months previously with sciatica. Hypodermic injection of acetate of morphia on the lower spine, repeated three times, relieved the pain, and she gradually recovered. After each operation she was entirely relieved, and remained so during a week, when the pain would return again, but not so severely, and finally it disappeared altogether. What advantages are secured by this mode of medication? 1. The remedy does not oppress the brain so much, nor do those unpleasant consequences follow its use by this method as when given by the mouth. 2. Less is required than by the mouth. 3. It requires much less time to pro-

duce the same effect. 4. In very many cases in which the effect of opium is desirable, the gastric complications prevent its accomplishments. (*Philadelphia Med. and Surg. Reporter.*)

SURGERY.

COMPOUND DISLOCATION OF THE FOOT. Dr. E. Coutagne of Lyons was called on December 31 to see a man aged 35, who had fallen on his left foot from a house of small height. The foot presented the appearance of valgus—the sole being turned outwards and backwards. Opposite the external malleolus there was a transverse wound, which extended some distance along the anterior surface of the dorsum of the foot, and through which projected the external angle of the trochlear surface of the astragalus. It seemed probable, however, that even more of the bone had projected at the time of the accident; for not only the integuments, but the patient's woollen stocking and thick gaiter, were penetrated. The malleoli were not fractured. The relations of the astragalus with the other tarsal bones did not appear to be disturbed; and the injury was therefore concluded to be, dislocation of the foot outwards, with almost complete laceration of the ligaments of the tibio-tarsal articulation, especially the external lateral ligaments, displacement of the astragalus outwards and forwards, extensive laceration of the soft parts, and a penetrating wound of the joint. Reduction was immediately attempted, and was effected with much difficulty, but with rapid cessation of the severe pain produced by the injury. As the astragalus returned into its place, Dr. Coutagne could see the tendons of the extensor muscles return to their position in front of the bone. The wound was dressed with collodion; and the limb, having been wrapped in carded cotton, was put up in Scultetus' apparatus, which, at the end of a month, was replaced by a starched bandage. There were no inflammatory or febrile symptoms; and, at the end of March, the patient could walk out with the aid of crutches. At the time of making the report, the patient was still rather lame, and his foot was deformed; this M. Coutagne attributed to the fact that the astragalus had become pushed somewhat forward, and he considered it probable that, in time, this condition would become ameliorated, and the patient's gait more steady. (*Gazette Médicale de Lyon*, 1 Fév., 1865.)

COMPOUND DISLOCATION OF THE TIBIA FORWARDS. At a meeting of the Surgical Society of Ireland, Mr. M. H. Stapleton related the following case. The patient was a male, aged about 32 years, in the enjoyment of good health until the occurrence of the accident; he was active, of abstemious habits. On March 2nd, he was hurrying down the doorsteps of a house, and on reaching the foot-path he made a spring with a long stride so as to get quickly across the road. He felt his heel slip, as if on a greasy surface, and fell. The foot was completely turned outwards and was quite powerless. When Mr. Stapleton saw him the foot was much shortened, whilst the heel projected considerably backwards; it was also drawn upwards and fixed in that position, the toes being turned downwards. The lower end of the tibia was prominent in front of the ankle-joint, and beneath it was a marked depression, the skin being very tense over the prominence. From a small wound not larger than a pin-hole exuded a pale fluid. The displaced parts were reduced without much difficulty, and without the use of chloroform, and the limb was placed in a box-splint. All seemed to go on well for a few hours, but then came on a series of dangerous symptoms—

spasm, pain, inflammation, erysipelas, diffuse inflammation, sloughing, etc., so that he was three times believed to be on the point of death. Amputation of the injured parts was performed on June 18th, and on the night of the day of the amputation he slept well, never afterwards complained of pain. The stump was perfectly healed on the fifteenth day. The injury, Mr. Stapleton observed, was one of dislocation of part of lower end of the tibia forwards. Both ankles were found in their normal position as regarded the astragalus. The fibula was fractured nearly on a line with the joint, its fracture being very oblique from above downwards and from behind forwards. The internal malleolus was also fractured obliquely, retaining with it a considerable portion of the posterior half of the lower articulating surface of the tibia. The anterior portion of the tibia with its articulating surface came forward and downwards, and rested on the neck of the astragalus. The posterior portion retained its normal position as regards the astragalus, and formed a bond of union between the fractured malleoli. The lower end of the tibia which was displaced forward, died to about the extent of an inch. (*Dublin Medical Press*, February 1st, 1865.)

A DISINFECTANT. Basic nitrate of bismuth, when applied to suppurating wounds, has been found to remove all smell, and hasten the healing up. It has been employed in scrofulous sores with much success. (*Chemical News.*)

MIDWIFERY AND DISEASES OF WOMEN.

LAWS OF THE PRODUCTION OF TWINS. Dr. Matthews Duncan, in a paper on this subject, attempts to demonstrate the following conclusions. 1. The largest number of twins is produced by women of from twenty-five to twenty-nine years of age; and on each side of this climax of fertility in twins there is a gradually increasing falling off in their number, as age diminishes on the one side and increases on the other. 2. Twins are not regularly distributed among births generally; their production, therefore, is not subjected to the same laws as govern ordinary fertility. 3. The mean age of twin-bearing mothers is greater than that of mothers generally. 4. Twins increase in frequency as mothers become older. This forms a striking contrast to the fecundity of a mass of wives (not mothers) which diminishes as their age increases. 5. Newly married women are more likely to have twins the older they are. 6. While the fecundity of the average individual increases with age till twenty-five is reached, and then gradually diminishes, there is some probability that the opposite is true, so far as regards twins alone, fertility in twins being greatest when fecundity is least, and *vice versa*. 7. The actual number of twins born of a mass of women in different pregnancies decreases as the number of the pregnancy increases. 8. The number of twins relatively to the number of children born in different pregnancies increases with the number of the pregnancy. In other words, a woman is more likely to have twins in each succeeding pregnancy than in the former pregnancy. The first pregnancy perhaps forms some exception to this rule. 9. In an individual twin-bearing is, of course, a sign of high fertility at the time. It also, in a mass of women, shows a high amount of fertility, at least till the time of the birth of the twins. 10. It is probable, though not proved, that twin-bearing women have larger families than women uniformly uniparous. (*Edin. Med. Journal*, March 1865.)

MIDWIFERY STATISTICS IN MOSCOW. The Rev. Professor Haughton, M.D., has communicated to the

Dublin Obstetrical Society some statistical returns which he had procured when in Moscow some time since from the lying-in hospital of that city. This hospital had also a foundling hospital in connection with it, but as to record, the two were quite distinct. From 1832 to 1860, inclusive, the total deliveries were: natural, 38,713; irregular (hand), 1,329; ditto (instruments), 739; twins, 846; triplets, 11; still-born, 3,450. Out of 45,088 deliveries, 739 were set down as having been effected by instruments. The crotchet was not recognised in Russia, the only instrument used being the forceps. Another interesting question arose: what became of this large number of children? Dr. Haughton found that out of 42,553 children there were: sent to the foundling hospital (boys), 21,944; girls, 20,525; taken home by mothers, 85. The boys were trained up for the Russian army, and the girls were instructed in various industrial occupations. It appeared that in Moscow, St. Petersburg, and other large Russian cities, the influx of men from the country seeking employment was so enormous that the men were four times as numerous as the women—a fact which accounted for the immense number of children born and then deserted. From the best information he had been able to obtain, the immorality of the cities occasioned by the excessive number of men was equalled by that of the rural districts arising from the opposite cause. The mortality of the children in the foundling hospital was 42 per cent. during the first three years after birth. (*Dublin Medical Press.*)

RETENTION OF URINE MISTAKEN FOR LABOUR. Mr. R. L. Johnson reports that he was called on to visit Mrs. T. Forty hours previously symptoms of labour had commenced, and had, since that time, increased hourly. The patient was 35 years of age, and of a weak habit of body. She had had four children, all of whom were alive, and were strong and healthy. She complained of periodic "bearing-down" pains, accompanied by a discharge; she could not walk, nor lie on either side; and the only relief she experienced was when on her back and with her extremities semiflexed, but in this position she could not for any length of time continue on account of "shooting-pains" in her back and a sense of suffocation. On examination, Mr. Johnson found her pulse 90, her tongue typhoid, her skin hot and clammy, and during pains copious perspiration visible on her head, face, and palms of her hands. She slept but little. She could form no opinion as to about the time of her expected confinement; but she considered her size to have increased very much within the last few days. Her stomach was irritable; her appetite poor; her bowels were constipated; and she had insatiable thirst. Her urine was high-coloured and contained pus; and it was stated therewith that each movement she made, and during the pains, a considerable quantity of urine passed involuntarily from her. The surface of her abdomen was tense, hard, and unyielding; a little below and to the left of the umbilicus there was dulness on percussion, whilst the remaining portion of the abdominal surface was tympanitic. Between each side of the median line and the recti muscles, and just above the pubes, were thumb-like prominences, very painful to the touch, and semi-elastic. Mr. Johnson was not permitted to pass a catheter; whereupon he cautioned his patient to get immediate medical aid, and then left the house. Three hours afterwards he was again sent for, and he then removed from the patient more than nine pints of urine. All "bearing-down pains" ceased for three months. They then returned, and brought with them a healthy female child. (*Dublin Med. Press*, March 15th.)

We beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, APRIL 1st, 1865.

MEDICAL ESPRIT DE CORPS.

UNTIL the members of the medical profession have sufficient *esprit de corps* to hang together and support each other's interests, we have little hope of any good being effected for us by Medical Councils or by Acts of Parliament. The men of law have a proper sense of what is due to themselves and their profession. They are never seen publicly competing one against another which shall do the work cheapest—underbidding and underselling their services. Consider for a moment the difference of the amount of work done by a Poor-law legal officer and a Poor-law medical officer, and then consider their pay. One is engaged morning, noon, and night; the other—the lawyer—for a few hours one day in the week; and yet it often happens that his salary is greater than that of the doctor. At all events, there is in no case any kind of fair proportion between the salary of the Poor-law lawyer and the Poor-law doctor.

The reason is plain and obvious. Doctors not only compete for the Poor-law offices, but they underbid each other; they fight for them one against another, which shall do the work cheapest. Lawyers compete also; but they do not underbid each other. This spirit of competition is unfortunately carried out wherever there is an opportunity for its practice. And it bears its unfortunate fruit.

The attempts of the Metropolitan Counties Branch of the British Medical Association to obtain a fair fee for the medical examiners under the Government Annuities Act have been completely defeated by this desire to get and do work cheaply. What could the deputation which waited upon Lord Stanley of Alderley, the Postmaster-General, say when they were told by him that he had already received letters from seven hundred medical men who consented to the half-crown fee proposed by him; and when he could quote the *Lancet* to them as also approving thereof? Well might Lord Stanley say that "he did not think the profession were dissatisfied with the low fees". More than this, Lord Stanley stated what is evidently the practice of the Government (at least, in relation to the medical profession); viz., "That it was the duty of the Government to get work done at

the lowest cost." We do not refer to this remark for the purpose of pointing out its manifest absurdity and untruth; and will only observe thereon, that if there be one fact more certain than another in every business of life it is this, that cheap work means bad work.

But we must lament over the condition of our medical society—over the fearful and fatal want of *esprit de corps* which characterises our professional relations; which leads seven hundred medical men to jump at half-a-crown, when they might, by unity, have obtained a proper fee; which seems to be ever driving us down one step lower in the social scale.

Assuredly, in a country where work is valued at the price at which it is done, men are very much estimated according to the price which they put on their services; and, assuredly, the cheaper medical men do work, the cheaper will be the estimation in which they are held by the world; and, what is still worse, the less will be thought of the scientific and high nature of the work with which they are engaged. What (as we have said before) can Acts of Parliament, can Medical Councils or Associations, do for a profession which commits deliberate suicide?

Look, again, at our army medical brethren's grievances. These had received the warmest sympathy of the profession; they were certain of obtaining immediate redress; the profession had the means of their cure in its own hands. All that was required was that candidates should for a time cease to apply for admission into the army. But we all know what has happened. When the British Medical Association was winning a certain battle for the army medical officers, its efforts were defeated solely by the members of the medical profession. Before such things as these, our best efforts are vain. Our own worst enemies, our only enemies, are ourselves.

MR. READE, the novelist, will have found in the papers during the last few months sufficient food for another romantic onslaught upon lunacy law. This time he will not have had altogether to draw upon his fertile imagination for his facts. He will now have distinct facts of illegal doings in respect of lunatics committed in this country. Our readers will remember the tale of the abducted lunatic nun, which a short time ago created a temporary sensation at Dover and elsewhere. In this case, it was admitted that the proceeding was illegal; but Sir G. Grey did not consider that any harm was done, or meant to be done; and, therefore, did not think it necessary to prosecute at law any of those parties who had acted illegally in the matter. But this tale is barely concluded, before another of a similar kind comes before the public.

It appeared that in 1863, Mr. Docknall, a bookseller, residing at Chester-le-Street, was, under the

orders of Colonel Johnson, a local magistrate, confined in the lunatic asylum, where he remained for five days. Colonel Johnson acted illegally, in the first place, in consulting only one medical man as to the state of mind of the alleged lunatic, in place of two, as the Act required; and to have acted even worse than illegally, in stating that he had examined Mr. Docknall personally, whereas he had never seen him at all. At the expiration of a very short time, the medical man in charge became convinced that Mr. Docknall was perfectly sane; and representations having been made, two magistrates went to the asylum, and, together with the medical men who examined him, being convinced that he was perfectly sane, restored him to liberty. Mr. Docknall was a poor man; but the occurrence having excited a great deal of feeling in the neighbourhood, he was advised to take proceedings against Colonel Johnson. An action was brought against Colonel Johnson for damages laid at £5000. But when the case came on at the summer assizes in 1864, the pressure of business was such that the Lord Chief Justice was obliged to leave for another assize town before it could be heard. Under these circumstances, the unfortunate man, naturally of an excitable temper, and having undergone great afflictions in the loss of his children and through domestic differences with his wife, was so overcome by this disappointment, following on his incarceration in the lunatic asylum, and on his unsuccessful applications for redress to the Home Office, that he put an end to his own existence.

Such was the case last week brought by Lord Malmesbury before the House of Lords. Lord Granville, in reply, stated the very apparent truth, that "no one could deny that it was most undesirable that any person should be confined in a lunatic asylum on the ground of insanity who was not really insane." Lord Shaftesbury indignantly attacked the question; and pointed out the very important fact, that the Lunacy Commissioners were not to blame in the matter.

He characterised the conduct of Colonel Johnson as most unwarrantable. If matters of this kind were to be overlooked, it was to no purpose that Commissioners were appointed, inspectors sent out, and laws passed for the protection of these unhappy persons. If the law was to be boldly and impudently evaded as it had been in this instance, things had come to a position in which commissioners and inspectors might as well resign their offices, and the legislature repeal all the Acts of Parliament upon the subject. The Commissioners of Lunacy were in no way chargeable with blame in this matter. Their jurisdiction over county asylums was very slight indeed, amounting only to power to make an annual visitation and report what they saw. Notice was sent to them of the admission of patients; but in this case it happened that the notices of admission and discharge arrived at the same time, and, therefore, there was nothing to call for their intervention. After the patient had been liberated, he called upon them to complain of his treatment; but the only answer which they could make was that the matter was totally beyond their jurisdiction. He must again press upon the House the absolute necessity that some opinion should be pronounced upon this great abuse of magisterial functions. Many of the magistrates in England were most admirable men, and rendered the Lunacy Commissioners very great assistance in the administration of the law; but there were a great many who rendered no assistance, and in some measure offered

obstructions to its enforcement. In this especial county of Durham, the Commissioners had more trouble in getting an effective visitation of the asylums than in any other in the kingdom.

Thus rests this matter at present. But as the papers called for by Lord Malmesbury are to be produced, we shall, of course, hear more of it.

On Tuesday last, a very interesting paper, by Dr. W. Roberts of Manchester, was read at the Royal Medical and Chirurgical Society. The subject of it was the Solution of Calculi in the Bladder and the Kidney. Dr. Roberts detailed in it a very great number of experiments which he had performed in order to place the proposed treatment on a scientific basis, which had never yet been done. He did not claim for the treatment any general application. He stated that it was only applicable in comparatively few cases: viz., in those cases where the stone was small, and was of the uric acid kind, and when the urine was not alkaline from disease. His treatment consists in the administration of large doses of acetate or citrate of potass, so as to keep the urine constantly of a certain degree of alkalinity. For weeks together, the patient may have his urine thus kept alkaline without injury. Dr. Roberts, in fact, considers the administration of alkalis in this way as harmless as the taking of so much sugar. The paper was remarkable as a methodical, scientific study; and, also, well indicates the immense service which we may anticipate that chemistry will one day render to medicine. The real value of the proposed remedy can of course only be decided by future experience.

THE Government Commission now engaged in investigating the Nature and Treatment of Venereal Diseases has, we believe, been transferred from the War to the Home Department. This fact corroborates the idea as to the objects of the Commission which we have all along maintained; viz., that if the Commission be of any service at all, it can be so only by recommending the Government to adopt some foreign police regulation of prostitution. It is hardly likely that the Commission, without instituting experiments, can tell us anything new or anything definite about either the nature or the treatment of venereal diseases. Their report in this direction can only be a summary of, or a judgment upon, the opinions of other persons on the subject. As, however, the Commission is engaged in so full an inquiry, we must say we feel somewhat surprised that they have not embraced in their consideration the subject of syphilisation. We would suggest, that the Committee might very usefully despatch a competent observer to Christiania to see and report upon the effects of Professor Boeck's treatment. Assuredly, a well drawn up and impartial report on the subject would be a great gain to the cause of humanity. If

Professor Boeck's treatment is a delusion (as we all seem to think), and can be shown to be such, as carried out in his own hands, then we shall in future have answer sufficient to those who would introduce the treatment into this country, or who may send their patients for treatment to Christiania. But if, on the other hand, the report should corroborate all that Boeck, Sperino, and others, have asserted of the treatment, then, also assuredly, the facts of the case should be more generally known and appreciated. There would be no difficulty in finding a competent observer ready and willing to go to Christiania as reporter; and we have no doubt that he would receive all attention at Professor Boeck's hands, and have every opportunity given him for judging of the method of treatment. Surely, Professor Boeck's treatment has as good a claim to the attention of the Committee, as have the opinions of Dr. MacLoughlin and Dr. Dickson (him of the *Fallacies of the Faculty*), both of whom have, we believe, already had an opportunity of fully stating their views and opinions to the Committee.

IN the JOURNAL of last week, we expressed a hope that the Royal Medical and Chirurgical Society would continue its scientific investigations. We are glad to hear that it is their intention to do so; and we believe that the subjects chosen by the Council for present investigation are: The Effects of Electricity as a Therapeutical Agent; and the Use and Application of Hypodermic Remedies.

THE political position held by Professor Virchow in the Prussian Chamber of Deputies is very remarkable. He stands, it would appear, almost as the leader of the liberal party. A few days ago, in answer to a speech of General von Roon, in which the liberties of the country were threatened, Virchow was put forward as spokesman of his party.

"Herr Virchow protested, in the name of the Liberal party, against a breach of charter being intended by them. It was the Government (he said) that had set aside the constitution. The Prussian Government had become a military one. The Minister of War was conducting himself like a Premier, and menacing constitutional changes. There was a Nemesis in history. If a rupture was brought about by Government, they would have to pay the penalty one day. If not the present, the next generation would demand guarantees against those incredible constructions which are now being put upon the Royal prerogative and the passage establishing it in the charter. [*Tremendous applause.*] As regards this House, you vainly try to terrify us by menaces. It is we who have taken our stand on the rock of right. Depend upon it, you will find us at the breach whenever the constitutional rights of the country are imperilled. [*Three rounds of cheers.*]"

It is a very rare thing to find the physiologist, the orator, and the politician so combined in a member of our profession.

THE *Sydney Morning Herald* gives the following account of the ceremony of presenting the Victoria Cross to Dr. Manley, R.N., and to Dr. Temple. Dr. Manley received the Cross for his gallant conduct in attempting to save the life of Captain Hay; and Dr. Temple, for his bravery in bringing in the wounded at Rangariri. General Cameron, in decorating the heroes before the whole staff and troops formed in a square, said:

"It redounded much to the credit of the Medical Department, that so many of its officers had distinguished themselves by acts of individual gallantry and bravery. Out of the small number of officers composing the department in New Zealand, no fewer than four had been decorated with the order of the Victoria Cross, including the head of the department, Inspector-General Mouatt, who had earned himself that coveted distinction by noble services rendered in the Crimea; and another officer, Staff-Surgeon Home, who had distinguished himself in India. During the war in New Zealand, all present could bear testimony to the skill, untiring zeal, watchful care, and attention, with which all the medical officers had performed their arduous, onerous, and responsible duties. Their duty required that they should follow the troops under a hostile fire, and amid the deadly assaults of the enemy; and how nobly and devotedly they had behaved!"

PROFESSOR BENNETT has lately published his long experience in the treatment of pneumonia by the "restorative treatment." Under that treatment, he tells us that he has not lost a single case of uncomplicated pneumonia. We cannot help contrasting with his results, the statement lately made by Dr. MacCormac of Belfast, when treating of the benefits of bleeding in pneumonia.

"I have never lost" (he says) "a case of uncomplicated pneumonia or pleuritis, to say nothing of other forms of inflammation; and I suppose I have treated as many in hospital and private practice as the generality of practitioners, in which I had resorted to resection, in my life." (*Dub. Med. Press*, March 22, 1865.)

One is reminded, in reading these opposite conclusions of experience, of Dr. Barclay's statement in his *Medical Errors*, to the effect that, in order to arrive at any definite conclusions as to the effect of any particular method of treatment over pneumonia, the results of as many as 20,000 or 30,000 cases are required.

THE difficulties attending the diagnosis of ovarian tumours in certain cases have received further illustration from the history of a case which lately occurred at the Middlesex Hospital. In this case, the tumour, which was considered ovarian, was found to be a tumour of the kidney, which occupied a very unusual position, lying, in fact, in front of the intestines. The removal of the supposed ovarian tumour was commenced; but its nature was discovered, and the operation, of course, desisted from. The patient died on the following day.

DR. OWEN REES reports a case of popliteal aneurism as large as a duck's egg, which was cured whilst the patient was under the influence of lead. The artery was to have been tied; but before the operation was performed, the patient was placed under Dr. Rees, that he might try the effect of the lead. On October 29th, the treatment commenced. The doses of lead were large and continued. Three grains of acetate of lead were given three times a day for six days; and then five grains were given, with a grain of opium. The five grain dose was continued for twenty-six days. The patient suffered only very slightly from colic. The aneurism had hardened much when the lead had been taken for three weeks. On Dec. 20th, the tumour was found to be fast diminishing in size; and on the 31st, he left the hospital to return to his work.

THE Manchester Ethical Association is, we learn, about to take up the important question of tariffs of medical charges; and will, we have no doubt, be glad to receive any suggestions on the subject. The opinions thereon of different medical men in different parts of the country would, doubtless, much assist the labours of the Society.

THE two Chemists and Druggists Bills, having been read a second time, have been sent before a Committee, where, it is understood, that the good in each will be subtracted, and made up into, we hope, a satisfactory Act of Parliament. The number of deaths which occur yearly through the ignorance or mistakes of druggist boys indicate clearly enough how necessary it is that the public should take steps to protect itself in the matter.

Apropos of M. Jolly's paper on tobacco, M. Bertillon calls to the mind of the profession the fact that he, in 1855, made an inquiry into the effects of tobacco on the mental performances of the pupils at the Ecole Polytechnique. He found that the smokers were decidedly behind the non-smokers in their examinations. At that time, the number of pupils was 160; and of these, 102 were smokers. He divided them into twenties; and found that, in placing them according to their merit at examination, there were among the twenty who stood first six smokers; amongst the second twenty, ten; and so on.

No. according to merit.		No. of smokers.	
1 to	20	.	6
20	40	.	10
40	60	.	11
60	80	.	14
80	100	.	12
100	120	.	15
120	140	.	15
140	160	.	16

So that the table shows that the more unfavourable their classification, the greater was the number of

smokers. Moreover, it was found that the mean rank of sixty-six determined smokers, on entering the school, was 94; and at the end of the year, 98; consequently they had *lost* 4 numbers. Whilst the mean rank of non-smokers was 71 at their entrance, and 67 at the end of the year; so that they had *gained* 23 places above the smokers—as much as the smokers had lost!

THE *Berlin. Klin. Woch.* (February 20th) gives an interesting paper showing the relative rank and pay of army surgeons in European countries. As regards pay of surgeons of similar rank, we have the following. In Prussia, the regimental surgeon's pay is from 700 to 1,200 *thalers*; in England, from 1,800 to 3,050; in France, from 780 to 1,740; in Belgium, from 1,260 to 1,700; in Hanover, from 950 to 1,400 *thalers*. As regards relative rank, in Prussia the regimental surgeon ranks with captain; in England, with the major and lieutenant-colonel; in France, with captain and chief of battalion; in Belgium, with captain and major; in Hanover, with captain and major.

Professor Polli, whose name is known to our readers, has been made a Knight Commander by the Bey of Tunis, by whom he seems to have been better appreciated than by his own Government.

In the Rochus Hospital at Pesth, on the 17th ult., Dr. Jaulus died of typhus, in his twenty-sixth year, a few days after the burial of his colleague, Dr. Kovachs, who died from the same disease in his twenty-fourth year.

On the 20th ult., the Caesarean operation was performed in the Clinical Lying-in Hospital at Vienna, by Professor Späth, in a young woman twenty-one years of age. The reason was on account of extreme narrowness of the pelvic opening. The mother died thirty-six hours after the operation. The child, which was fully developed, is alive and well.

The Jubilee of the Vienna University, which has excited so much ill-feeling among professors and students, is at last fixed for the beginning of August—the most inconvenient time which could have been chosen, says *Wien. Med. Woch.*; unless, indeed, the intention was to convert a solemn festival into a family party!

The *Wien. Med. Woch.* announces the death of Dr. Förster, the pathological professor at Würzburg.

"All contagious diseases" (says M. Diday), "which remain local, depend upon the presence of a parasite. Consequently, in accordance with this law, we shall certainly find the parasite which produces a chancrelle."

The Report of the Committee composed of MM. Flourens, Dumas, Brogniart, and Milne-Edwards, on the subject of spontaneous generation, is as follows:—"The facts observed by M. Pasteur, and

contested by MM. Pouchet, Jolly, and Musset, are perfectly correct. Fermentable liquids may remain either in contact with confined air, or in contact with air frequently renewed, without undergoing any alteration. When, under the influence of the air, living organisms are developed, their development must not be attributed to its gaseous elements, but to the solid particles contained in it, and of which it may be freed by different methods, as M. Pasteur has affirmed." The question of voting these conclusions of the Report appears to have excited quite a scene in the Academy. MM. Le Verrier, Flourens, and others, objected to the Academy giving its approbation of them, on the ground that the vote of the Academy could add nothing to the force of the Report; and that as the Academy, as a body, did not witness the experiments on which the Report was founded, it was not in a position to express an opinion on the subject. M. Velpeau was greeted with "murmurs" when he asked, "How can the Academy vote as to the exactitude of experiments which it has not witnessed?" M. Le Verrier interrupted the President; and, when the vote was taken, declared that "it was doubtful"—a remark which excited "violent reclamations", and brought M. Milne-Edwards on his legs to demand, "with great animation," that the vote should be taken over again; which it was, and with the same results. "Why don't you vote, Mons. Le Verrier," asked the President, "against the Report?" "You have no business, sir," answered the astronomer, "to ask me the question!" From all this, we may conclude that the last word has not yet been said about spontaneous generation. MM. Pouchet and Jolly have evidently some very warm supporters in the Academy.

The Academy of Medicine, in an address to all the vaccinators in France, said in 1830: "Innumerable facts have demonstrated that the vaccine virus taken from persons subjects of diseases which are capable of being communicated by contact, such as syphilis, small-pox, etc., is never mixed with any of these, but produces solely the vaccine pustule."

The present Dean of the Faculty of Medicine of Paris is M. Tardieu. His immediate predecessors were Orfila, Rayer, Paul Dubois, and Bérard.

Four hundred and fifty boys at the Lyceum, or school, at Vanves, were lately vaccinated with matter taken direct from the cow. The vaccinations succeeded perfectly even in the case of a larger number who had been vaccinated soon after birth.

The Triennial Prize of 20,000 *francs*, founded by Ribéri, will be given at the end of 1867. Seven of these prizes in all will be given—lasting for twenty-one years. All works on Surgery, in MS. or published during the triennial epoch, may compete for it. They must be written in Italian, French, or Latin.

Association Intelligence.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
WEST SOMERSET. [Quarterly.]	Clarke's Castle Hotel, Taunton.	Wednesday, April 12, 7 P.M.
BATH AND BRISTOL. [Ordinary.]	Victoria Rooms, Clifton.	Thursday, April 13, 7 P.M.

WEST SOMERSET BRANCH.

A QUARTERLY Meeting of this Branch will be held at Clarke's Castle Hotel, Taunton, on Wednesday, April 12th, at 7 P.M.

Notice of papers or cases to be communicated should be sent to the Honorary Secretary previous to the meeting.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, March 11th, 1865.

MEDICAL BENEVOLENT FUND.

At a meeting of the Committee of the Medical Benevolent Fund, on Tuesday, March 28th, the Treasurer reported the receipt of £2635 from the residue of the estate of the late Mr. Hine, making £5635 in all bequeathed by him to the Fund. The Committee at once resolved that five additional annuitants should be elected.

REPORT OF MEETING OF COMMITTEE OF COUNCIL:

Held at Birmingham, March 23rd, 1865.

PRESENT—Sir Charles Hastings, M.D., D.C.L., etc. (in the Chair); Mr. Bartleet; Dr. Bryan; Mr. Clayton; Dr. Falconer; Dr. Richardson; Dr. Stewart; Dr. Wade; Dr. Westall; and Mr. Watkin Williams (General Secretary).

The following resolutions were adopted.

1. That Professor Stokes, M.D., of Dublin, be appointed to deliver the Address in Medicine at the annual meeting of the Association.
2. That Professor Syme, of Edinburgh, be appointed to deliver the Address in Surgery at the annual meeting of the Association.
3. That the Treasurer's Financial Report be received, adopted, and published in the JOURNAL.
4. That the "Northern Branch" be recognised, and the laws adopted.
5. That the annual meeting be held on Tuesday, Wednesday, Thursday, and Friday, August 1st, 2nd, 3rd, and 4th, 1865.
6. That Dr. Jeaffreson, Dr. Richardson, Dr. Falconer, Dr. Wade, Dr. Stewart, and the General Secretary, be appointed a subcommittee, to make the arrangements for the annual meeting, in concert with the local committee; and especially to consider what measures it may be expedient to adopt in reference to the giving in and reading of papers; and to report to the next meeting.

T. WATKIN WILLIAMS, *Gen. Sec.*

13, Newhall Street, Birmingham, March 28th, 1865.

FINANCIAL REPORT.

It is very satisfactory to be enabled to report a very improved condition of the finances of the Association, as compared with that of last year. The accounts have been audited by Dr. Melson and Mr. Hadley; and they find that after payment of all bills due from the Association, the Treasurer held a balance of £243:16:8½ on the 31st of December 1864; whereas, in December 1863, there was a balance of £8:0:3½ due from the Association to the Treasurer. This result is the more gratifying, as some extra sums have been paid, not of an ordinary kind, which have added to the amount of the expenditure.

The following is the statement of the accounts.

1864.—RECEIPTS.		£	s.	d.
Subscriptions	2501	2	0	
Advertisements and Sales	633	11	6	
	3134	13	6

CHARLES HASTINGS, *Treasurer.*

THE ANNUAL MEETING.

In reference to the resolution (5) of the Committee of Council, by which the days of the annual meeting are increased from three to four, Dr. Jeaffreson (President-elect) writes as follows to the General Secretary.

"I fully concur with the Committee of Council in their suggestion of making the duration of our meeting four instead of three days; and suggested this to several of my friends at Cambridge. The business affairs of the Association have necessarily much increased, and consequently too little time has been left for the reading and discussion of scientific papers, a thing which is to my mind the most interesting, if not the most important, feature of our general meetings. I hope that you and all the members of the Association will bestir yourselves to get promises of papers. Should the number of papers be very considerable, it will be easy for us, with our excellent accommodation of rooms, to adopt a scheme of sections, should such be thought necessary or advisable.

"Your letter came too late for me to call a meeting of the Local Committee; but I have canvassed several of the most important members, and all agree with us in the propriety of commencing our proceedings on Tuesday, the 1st, instead of Wednesday, the 2nd of August."

Reports of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 28TH, 1865.

R. PARTRIDGE, Esq., F.R.S., President, in the Chair.

CASE OF ICHTHYOSIS OF THE TONGUE.

BY J. W. HULKE, F.R.C.S.

ICHTHYOSIS is a term provisionally applied by the author to an affection of the mucous membrane of the tongue, which consists in hypertrophy of its epithelial and papillary tissues. It is characterised by yellowish-white, raised, tough, leathery patches, which are clinically distinguished from syphilitic nodes, condylomata, and cancer. Mr. HULKE had seen but one case, which he related.

REMARKS UPON OSTEOMYELITIS CONSEQUENT ON GUNSHOT WOUNDS OF THE UPPER AND LOWER EXTREMITIES, AND ESPECIALLY UPON THE TREATMENT OF STUMPS AFFECTED WITH OSTEOMYELITIS AFTER AMPUTATION NECESSITATED BY SUCH INJURIES. BY THOMAS LONGMORE, ESQ. (DEPUTY INSPECTOR-GENERAL.)

The author commenced his communication by noticing the particular interest which had been excited amongst military surgeons, especially French surgeons, during the last few years in the subject of osteomyelitis, or endosteitis, as it is called by some writers, after gunshot wounds of the extremities, and of its proper treatment. The interest arose, not from any belief that a difference existed between the nature of the inflammation of the medullary tissue when developed after gunshot injuries and the corresponding inflammation occasionally seen after the ordinary injuries and amputations of civil life; but from the comparative frequency of its occurrence after gunshot injuries, and after amputations consequent upon them, together with its severe and obstinate character, often in men of previously sound constitutions, in military practice, contrasted with the comparative rarity of its occurrence in sound constitutions in civil practice. After the Crimean campaign, Dr. Valette, a French military surgeon, who had had one of the large hospitals at Constantinople under his charge during the period of the war, and again, since the Italian campaign of 1859, M. Jules Roux, the principal surgeon at the large marine hospital of St. Maudrier at Toulon, had both written at considerable length on the subject. Dr. Valette's observations were chiefly directed to this inflammation in its earlier and more acute stages, as witnessed amongst the wounded sent directly after the battles of Alma and Inkermann, amongst whom it had produced the most fatal consequences. The author remarked that in perusing Dr. Valette's reports the conclusion could scarcely be avoided, that the so-called osteomyelitis in a large number of the instances referred to must have been truly cases of pyæmic poisoning, and that in all, the symptoms of the osteomyelitis must have been greatly aggravated by circumstances tending to the development of pyæmia. Dr. Valette found all attempts to check the disease ineffectual, and came to the conclusion that all resections and amputations for the effects of this inflammation after gunshot fractures should be abandoned, and exarticulations substituted, the wounded being scattered at the same time in tents as widely as possible.

M. Jules Roux's observations were made on the disease in its more chronic condition, and he was led

to advocate the same views with regard to the necessity for exarticulation as had been advocated by Dr. Valette. M. Roux had under his care about 2,000 soldiers who had been wounded in the Italian campaign, a considerable number of whom presented diseased conditions demanding consecutive amputation or other surgical interference. At first M. Roux practised amputation, but with such unfavourable results that he was induced to try exarticulation in similar cases instead. This operation proved remarkably successful. There was no death out of twenty-two successive cases, among which were four cases of exarticulation at the hip-joint. In a memoir on the subject which was read before the Imperial Academy of Medicine at Paris in 1860, M. Roux argued that when osteomyelitis after gunshot wounds assumes a chronic form, amputation generally only takes away a portion of the inflamed bone, and in consequence of this incompleteness in the operation the disease is aggravated in the remainder. Hence, he asserted, the failures of secondary amputations for gunshot wounds of the bones; and hence also, in his opinion, the preference which ought to be given to exarticulation, or removal of the whole of the diseased bone, when a surgical operation becomes indispensable.

The views of treatment propounded by M. Roux had led to several protracted discussions at the Academy of Medicine at Paris. They were particularly analysed in an elaborate discourse by Baron Larrey, which he afterwards published. In this discourse Baron Larrey arrived at certain conclusions, six in number, with the general terms of which the author said he believed most English army surgeons would agree. The following were the conclusions referred to.

1. Osteomyelitis after gunshot wounds is more frequent than has been hitherto supposed; but is not inevitable, and in most instances is a means of cure.
2. It may either be limited to a given point of the bone, extend itself partially, or invade the whole of the bone more or less quickly.
3. Every rational mode of treatment must be adopted in the first instance. We are encouraged to do so because we know osteomyelitis is susceptible of spontaneous cure.
4. Sometimes it necessitates resection, and sometimes consecutive amputation, and sometimes, in certain cases, exarticulation is preferable.
5. The existence of osteomyelitis is sufficient to explain the want of success which occasionally follows partial operations in bones affected with this inflammation. But,
6. It does not justify the too exclusive proposition in surgery, that resection of joints and amputations in the shafts of bones are to be abandoned for exarticulation in all such cases.

Mr. LONGMORE thought, however, that the settlement of the question of the proper treatment of chronic osteomyelitis might be carried a step further in precision, especially in cases where want of success had seemingly followed partial operations on account of its presence. Many cases, he stated, came before military surgeons, in which, after amputation had been performed in continuity for gunshot injuries, or for the effects of osteomyelitis consequent upon them, the portions of the limbs left afterwards presented such diseased conditions as to necessitate further surgical interference in order to avert fatal consequences from the patients. In these cases, where the morbid state of all the tissues is manifestly due to the continued osteomyelitic action subsequent to the amputation, what is the course to be pursued? The arguments of M. Jules Roux would urge most forcibly in these cases, that exarticulation is the only treatment that can scientifically be adopted; and

even according to the conclusions of Baron Larrey, these would appear to be "the certain cases" to which he refers in his fourth conclusion, where curative treatment in the first place and consecutive amputation in the next place having failed, disarticulation would be the preferable course to follow. The author had been led to adopt a different conclusion; and, in order to show to the Society the grounds on which his conclusions had been based, he called attention, firstly, to certain preparations belonging to the museum of the Army Medical Department from cases in which exarticulation had been performed or death had occurred on account of osteomyelitis; and secondly, to the histories of some similar cases in which a cure had been effected without exarticulation being resorted to.

The first three preparations exhibited consisted of the upper portions of three humeri. In each of these the history was—amputation at the middle of the upper arm for a gunshot wound, and exarticulation at the shoulder within a year afterwards for osteomyelitis. The fourth preparation was one of the upper part of the femur which had been removed from the patient after death. Amputation had been performed in the middle of the thigh for a gunshot wound in India, and the patient died about a year afterwards from the effects of osteomyelitis in the stump. There was every reason to believe that in all these cases the osteomyelitis was due to the shock of the original gunshot injury, and not to any peculiarities in the amputations or other causes. To show that the simple shock of a gunshot wound is capable of giving rise to general endosteitis in a bone, another preparation was exhibited in which the entire shaft of the femur had been subjected to the action of this inflammation. In this case a musket-ball had only penetrated the soft tissues, and struck the bone, without producing complete or even a partial fracture of its substance.

Another preparation of the upper half of a humerus was exhibited from a case in which the author had performed exarticulation for osteomyelitis four years ago, before his attention had been turned to other modes of treatment. In this case the previous amputation had been performed for the effects of a kick from a horse, and the preparation was exhibited to show that the consequences of the osteomyelitis were exactly similar to those which had occurred after the gunshot injuries.

All the preparations above named showed that in each case extensive necrosis of the shaft had resulted from the endosteitis with which it had been affected; that the necrosed portions were well defined within fixed limits; that in no instance was the necrosis continued to apophysis, although in all the cases the apophyses were more or less in the condition known by the term "osteoporosis;" and that the sequestered portions of the shafts were surrounded by copious shells of new bone, as in cases of ordinary necrosis.

Three cases were then related, in which amputation at the middle of the thigh had been followed by osteomyelitis in the stump, but in which cures had been obtained without exarticulation. The amputation had been performed in two of these cases for gunshot wounds, in the third for the consequences of a compound fracture from a fall. In each of these cases the removal of the sequestra left by the osteomyelitic action was effected by surgical interference, and a sound and healthy condition of the stump resulted. In the case first described, the patient at the time of his admission into hospital at Fort Pitt, from India, had suffered so severely from the effects of the prolonged irritation to which he had been subjected, and the thigh-stump was so extensively dis-

eased throughout, that at a consultation of the staff of the hospital the removal of the stump at the hip-joint was determined to be the only course which held out a fair hope for the patient's recovery. Fortunately, before this serious operation was undertaken, a study of the preparations laid before the Society, and some others of a similar kind, led the author of the paper to determine, as a preliminary measure, to open freely the cicatrix of the amputation-wound, and to take steps for removing all pieces of necrosed bone that might be found within the remaining portion of the shaft. The operation was so conducted that, if necessary, it could have been converted at the time into amputation at the hip-joint, or this formidable operation be reserved for a subsequent resource, if the removal of the necrosed bone did not lead to cure. Complete success, however, attended the first effort; the dead portion of the shaft, which reached up to the trochanters, was extracted, together with some smaller detached fragments. The patient rapidly improved in all respects afterwards, and eventually walked from the hospital with an artificial limb applied to the stump, which had become perfectly sound.

The second and third cases mentioned were those of soldiers who had suffered amputation of the thigh for gunshot wounds, and from subsequent endostitic necrosis in the stump. In both cases the necrosed portions of the shaft were removed by gradual traction through openings in the line of cicatrix of the amputation-wound. In one of these instances, in which the man's limb had been smashed by a round shot just above the knee, at Lucknow, in 1857, an opportunity was afforded of examining the state of the stump five years after the date of the amputation. The stump was then thoroughly sound, and the man able to perform hard work and long journeys by wearing an artificial limb upon it. The motions of the hip-joint were perfect.

The author of the paper stated his present conviction to be that if similar steps had been adopted, and the necrosed sequestra removed, in the instances brought before the Society in which exarticulation at the shoulder had been performed by himself and others, the stumps might have been similarly preserved; and that in the instances of the femoral stump, and the femur affected with endostitic necrosis, the lives of the patients might probably have been saved by such a proceeding. In cases where amputation had been previously performed, the amputation cicatrix should be opened for the removal of sequestra, or, if more convenient, the stump could be opened from other directions; where no previous amputation had been done, the sequestra should be extricated as in ordinary cases of necrosis.

Though not a matter of such importance to avoid exarticulation of a humeral stump as it is of a femoral stump, owing to the danger to life in the latter operation, and the important use of a thigh-stump for the adaptation of mechanical contrivances for assisting in supporting the weight of the body, yet the author maintained the preservation of a humeral stump to be of great value to the possessor, especially when the power of compressing it to the side is retained.

An osteoporotic condition of the articulating heads of the bones, corresponding with the condition shown in the preparations, will not interfere with a successful result if the necrosed sequestra be completely removed. The author alluded to a case in which he had removed a foot at the ankle-joint, in which, on sawing off the two malleoli, the extremities of both the tibia and fibula were seen to be extensively affected with fatty osteoporosis; yet the ends of these bones became firm and solidified under an improved condition of general health, the removal of the

source of irritation which had previously existed in their immediate neighbourhood, and the stimulus of use. There could be no doubt that the head and neck of the femur in the case of the thigh-stump which had been preserved by the removal of the sequestra, the largest of which was exhibited to the Society, was in a state of osteoporosis at the time these sequestra were extracted. The amount of irritation to which the bone had been subjected, the length of time that had elapsed, together with the conditions observed in analogous cases where the opportunity of examining the conditions had been afforded, sufficiently established the fact.

The author concluded by observing, that while adopting generally the views of Baron Larrey, before quoted, in reference to the nature, progress, and treatment of osteomyelitis after gunshot injuries, the following appeared to be fair deductions from the facts and observations he had brought to the notice of the Society.

1. In gunshot injuries of bone, it will be found for the most part—that what might be anticipated from the intimate connection which exists between the periosteal and endosteal investments of the bony tissues, and from the violent general mischief effected by the stroke or passage through them of a projectile—that all the structures participate not only in the immediate local destruction, but also in the extended inflammation which follows, whether the inflammation after a time subsides and terminates in repair, or whether it continues in a chronic form.

2. There exists this difference between the inflammation of the endosteum and that of the periosteum; that of the endosteum has a special tendency after gunshot injuries to degenerate into a chronic condition analogous to that of suppuration in other tissues, to extend itself along the cancellated structure, and thus to produce disintegration and death of the bony substance; that of the periosteum, at the same time, will exist only to such a degree as to cause it to exert a protective influence by the formation of new bone around the diseased tissues, just as in ordinary cases of necrosis from other causes.

3. If amputation in continuity be performed while the endosteum is suffering from the inflammatory irritation excited by the violent injury to which the whole bone has been subjected, especially when this has assumed a chronic form, the endostitis will most probably still pursue its course, even though the divided soft parts may at first become healed, slowly inducing death, more or less extensive, of bony tissue, and in time the usual consequences of such a condition throughout the whole stump.

4. The morbid condition of the endosteum does not usually extend from the shafts of bones into their apophyses.

5. When amputation has been followed by these consequences, exarticulation should not in any case be resorted to for the removal of the diseased stump, until the effect of complete extraction of the dead bone by proper surgical interference has been ascertained.

6. Experience shows that, even although a patient's constitution may be greatly impaired by the prolonged local diseased action to which it has been subjected, and though there may be every reason to conclude that the articular extremity of a bone is in the condition understood by the term "osteoporosis," yet the complete removal of the endostitic sequestra may speedily be followed by restoration of the general health, and by a condition of the stump so sound and firm that it may be applied to any purpose of utility for which, according to its length and position, it may be competent.

Correspondence.

SYPHILISATION AS A MEANS OF CURING CONSTITUTIONAL SYPHILIS.

LETTER FROM PROFESSOR BOECK OF CHRISTIANIA.

No. I.

SIR,—In your JOURNAL of Feb. 4th, Mr. Lee speaks of a patient whom I have cured by Syphilisation. Mr. Lee is of the "decided opinion" that this patient must not, as I believed, have been suffering from tertiary syphilis, but rather from "softening of the bones." I cannot, of course, know whether such a disease has developed itself since this patient left Norway; but I am quite sure that *he had tertiary syphilis* when he came here; and I say, with Professor Simpson, that I have never in the course of my experience seen a more decided case of tertiary syphilis.

On his arrival at Christiania, t^his patient was suffering from exostoses of both tibiae and of the sternal extremity of the left clavicle, and there was thickening and hypertrophy of the frontal periosteum. A bad smell issued from the nose, with separation of small pieces of bone from it; and during his stay here, so large a portion of bone separated from the hard palate that for several weeks any liquid that he put into his mouth came out through the nostrils.

As far as I am acquainted with softening, or mollities, of the bones, it is a very rare disease in the bones of the face—if it ever exist at all in that part; and the "softening of the bones" of the face, together with caries, is a pathological conjunction which, I confess, I have never heard of. I must, therefore, request Mr. Lee to explain what form, species, or type of "softening of the bones" has existed in this case—what, in his opinion, was really the disease, if it was not tertiary syphilis.

To prove that our patient was suffering from "softening of the bones", Mr. Lee states that a relation of the patient has told him that his father died of softening of the bones. Was that relation a medical man? Had he the patient under treatment? Was Mr. Lee acquainted with the history of the case, and the results of the *post mortem* examination? Softening of the bones is of so rare occurrence with men, that loose statements cannot be depended upon, especially when they are used to accuse colleagues of having made such a gross mistake, as I should have made if Mr. Lee's statement were correct.

But it is easy to see the real bearing of Mr. Lee's remarks. Like most others, he considers Syphilisation such a strange and incredible mode of cure, that when the patient told him he had been restored to health by it, during his stay in Christiania, Mr. Lee at once set it down that the patient had not had tertiary syphilis at all. This is the only person that has passed under a full course of treatment by Syphilisation whom Mr. Lee has, apparently, had an opportunity of seeing; and if I had been in Mr. Lee's place, I dare say I should have been equally incredulous. But I have now seen many hundreds who have been

successfully subjected to this same treatment; and, consequently, I was not surprised at the termination of the case. Such is a matter of common and constant occurrence here; and, hence, it was not necessary for me to resort, like Mr. Lee, to any improbable or impossible explanation of the result.

But what I am still more surprised at than the assertion by Mr. Lee of my erroneous diagnosis, is the following passage: "The absence of any eruption in this case, and the interval of some years between the appearance of the supposed primary and secondary affections, would of themselves be sufficient to lead to the inference that the patient's symptoms were not syphilitic."

Two questions are contained in this quotation.

1. Can tertiary syphilis break out after primary syphilis, without secondary symptoms having appeared?

2. Can several years elapse between the breaking out of the primary and the tertiary forms?

First Question. How far the tertiary form can break out without secondary symptoms having previously appeared, is a theoretical question which we shall never be able to get answered satisfactorily. My own opinion, however, is that between the primary and tertiary form there really do exist secondary symptoms. But, for all practical purposes, the case is this: that secondary symptoms may be so slight that the patient is not even aware of their existence, or, at all events, does not connect them with the primary syphilis from which he has previously suffered. I will give one or two instances.

Last year, a man was brought to my Hospital, suffering from subcutaneous tuberculo-serpiginous syphilide—consequently, a very decided case of the tertiary form. I knew the man very well; he had been in the hospital for primary syphilis three years before, and whilst he was there on the first occasion the constitutional complaint broke out. But, just as he was about being treated for this, he was attacked by pneumonia; and, while thus suffering, the symptoms of secondary syphilis, which had begun to show themselves, disappeared. On recovery from the attack of pneumonia, he left the hospital, without being subjected to any anti-syphilitic treatment. But on my asking him last year whether any eruption had made its appearance during the interval, he answered in the negative; and on examining him still more closely, it appeared that he was totally ignorant of the fact of his having suffered at all from constitutional symptoms when formerly in the hospital.

In the eighth plate of the work published by Dr. Danielssen and myself on Diseases of the Skin, you will find a case of subcutaneous tubercular syphilide on the left leg, in connection with a disease of the bone. On closely examining the patient, he said that half a year after the primary affection he felt some slight pain in his throat, which lasted, however, but a short time, and for which he did not consult any medical man; and he had never for a moment imagined that this trifling pain in the throat could have anything to do with the syphilitic affection.

Second Question. On this point, I did not think there could be more than one opinion; viz., that we know how early tertiary syphilis can develop itself after primary, but we are unacquainted with the utmost limit of its development—or rather there exists no such limit. In the above-mentioned case, cited from the work by Dr. Danielssen and myself on the Diseases of the Skin, no less than twelve years had elapsed between the primary and tertiary affections; and many cases have come under my notice in which a still longer time had intervened.

In another letter, I shall describe the method of Syphilisation which I follow, and its results.

I am, etc.,

W. BOECK.

Christiania, March 4th, 1865.

CHANGE OF TYPE IN DISEASE.

LETTER FROM W. O. MARKHAM, M.D.

SIR,—I am glad to find that Dr. Barclay gives up one of the two legs upon which he rested his idola of change of type in disease.

Your readers will remember that Dr. Barclay originally objected to my argument against the theory in this way: You have, he said, staring you in the face two unanswerable facts—viz., the advent of cholera into this country, and the exit of plague from it; and yet you tell us that there is no such thing as change of type in disease!

In his letter of last week, however, Dr. Barclay himself admits that one of these facts—the plague—is not satisfactory; and that it may be fairly explained away by "improved sanitary arrangements". He at present, therefore, rests his argument solely upon the cholera; so that his original statement may now be said to go upon crutches. On further consideration, he will, I am satisfied, also give up the cholera as a fact demonstrative of change of type in disease. If there be one lesson more than another which Dr. Barclay's book on *Medical Errors* teaches us, it is this: to avoid illogically connecting together a sequence with an antecedent, so long as attendant disturbing causes have not been satisfactorily disposed of as possible agencies of causation. Now, Dr. Barclay must forgive me if I remind him that, in this instance of cholera, he himself has forgotten the lesson he has pressed so home upon others. If the simple fact of cholera appearing in this country be any indication of change of type in disease, Dr. Barclay is bound to show, or give good reasons for the belief, that the poison had often previously swept across the land as a malaria, or been introduced into it by the way of contagion, and yet had taken no root, because men's bodies were not then typically ready for its entrance, or because they had not yet got that sort of constitution which is a proper pabulum for the poison. But Dr. Barclay knows well the history of cholera. He knows that it advanced from the East step by step, desolating and destroying; that we heard of its coming, and predicted its coming, long before it arrived; and that, whether it be contagious or not, it most assuredly followed the exact course which a contagious disease follows when it spreads itself far and wide. How then can my friend assert that the fact of such a disease as this falling upon us, and coming to us by traceable stages direct from the country of its probable birth, is a proof that disease has changed its type? Surely, if the proof of the theory is ever to be given, it must come from the grounds upon which I argued against it—viz., from proofs that well-known ordinary diseases here, under our own very eyes, have changed their character.

I must again say, that to me it appears we might just as reasonably say that diseases had changed their type among the Ojibbeway Indians when civilisation introduced small-pox among them, or among the New Zealanders when it introduced into their country the larger disease, as say that the presence of cholera in England is a proof that diseases have changed their type. I am, etc.,

W. O. MARKHAM.

3, Harley Street, March 27th, 1865.

GOVERNMENT INSURANCES AND MEDICAL FEES.

LETTER FROM JAMES REID, Esq.

SIR,—I am sorry to learn by the JOURNAL of March 18th, that the Metropolitan Counties Branch have failed to impress upon the Postmaster-General the justness of their appeal for fair remuneration to the medical referees under the Government Insurance and Annuities Act.

It appears to me that we have ourselves to thank for the low opinion government takes of our services, and of our *own* regard for what we do. The unjust scale of fees regulated by the sum insured, which so many assurance offices adopt, and which many medical men so readily accept, has been a plan which the government have followed in getting their work done at the lowest cost; just as they adopted the medical club system of a penny per head per week in fixing the remuneration for a civil practitioner in attending upon troops. This system found favour with some medical men, and fierce contests took place to obtain these appointments to medical clubs, all which government appreciated in the true free trade spirit, when they wanted to fix the payment for medical attendance upon their soldiers. I cannot so much blame government in this as ourselves; but I do find fault with the injustice of requiring the expenditure of the same amount of time, skill and thought being paid by different sums of money, according to the sum to be assured. We are asked to determine the healthiness and probable duration of a life, and do not want to know the amount to be insured in order to solve this proposition—indeed we shall decide best by knowing nothing about it. The work to be done is uniform in all instances; it should be met by a uniform fee, and should be kept free, to the interest of all parties, from any sliding scales of carefulness on the one hand, or payment on the other. If there was any justice in the money scales it should be 2s. 6d. for £50, 5s. for £100, 7s. 6d. for £150 insured, and so on. I know it is pleaded that these small sums cannot meet the expenses of insurance unless the medical man is content to take the small remuneration; then, I say, do without the medical opinions and take the risk—it is but a small one; or reduce the work and responsibility by merely requiring a general inspection and certificate as commonly suffices for a benefit society; otherwise it is robbing the medical man to pay the expenses of insurance. Again, *charity* is pleaded; but this is nonsense, for it is absurd to take from a man's pocket, or his fair remuneration for your own profit, or that you may not suffer, and call it charity. I have held some such arguments as these with various assurance offices, and many years ago refused the glitter of the New Equitable's two guineas, because under it there was an arrangement about less fees on the smaller sums insured. I have steadily declined to have anything to do with them, and shall treat this new government insurance and annuity society, whilst their present plan continues, in the same way. This act of the Postmaster-General will confirm the various insur-

ance societies who have acted on this principle, and embolden them to proceed yet further in this direction.

I hope some means may be devised, by memorial or otherwise, by which a few thousand opinions may be sent to the Postmaster-General to meet the seven hundred letters of consent to his proposal. The measure of government insurance and annuities is a good one, and deserves to be well carried out, but not at the expense of, or injustice to, the medical profession. I am, etc.,

JAMES REID.

11, Bridge Street, Canterbury, March 21st, 1865.

Medical News.

APOTHECARIES' HALL. On March 23rd, 1865, the following Licentiates were admitted:—

Griffith, Griffith, Edeyrn, Pwllheli, Carnarvonshire
Griffith, Thomas, Merthyr Tydvil
Orton, George Hunt, Narborough Hall, Leicestershire
Worthington, James Vince, Ulverstone, Lancashire

At the same Court, the following passed the first examination:—

Burn, William Barnett, St. Bartholomew's Hospital
Ellis, William Henry, St. Bartholomew's Hospital
Quick, John, St. Bartholomew's Hospital

APPOINTMENTS.

DUCKWORTH, Dye, M.D. Edin., elected Assistant-Physician to the Royal General Dispensary, Bartholomew Close.

ROYAL NAVY.

GRIGG, Joseph, Esq., Assistant-Surgeon, to Greenwich Hospital.
JAMESON, Thomas, Esq., Assistant-Surgeon, to the *Victory*.
REDMOND, William, Esq., Assistant-Surgeon, to the *Asia*.
STEWART, William H., Esq., Acting Assistant-Surgeon, to the *Royal Adelaide*.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.= Rifle Volunteers):—

HORGSON, F., Esq., to be Honorary Assistant-Surgeon 5th Yorkshire A.V.
NASON, R. B., Esq., to be Assistant-Surgeon 1st Administrative Battalion Warwickshire R.V.
TREED, F., Esq., to be Surgeon 1st Administrative Battalion Flintshire R.V.
THOMPSON, A. B., Esq., to be Honorary Assistant-Surgeon 19th Essex R.V.

DEATHS.

BROWN, Robert, M.D. (Staff-Surgeon Royal Army, and Medical Superintendent of Quarantine at Standgate Creek), at Strood, near Rochester, aged 84, on March 25. His full-pay service extended over sixty-two years.
BULLER, R., Esq., Surgeon, at Bampton, Oxfordshire, aged 84, on March 12.
HARDEN. On March 20, at Brixton, Maria, wife of Charles Harden, Esq., Surgeon.
*HILL, John, Esq., at South Cave, Yorkshire, on February 22.
JOLLYE, Edward W., Esq., Surgeon, at Norwich, on February 20.
LORD, James, Esq., Surgeon, at Fleetwood, Lancashire, aged 45, on March 16.
MCCOLLAR, John R., Esq., Surgeon, at Beeth, Yorkshire, aged 51, on March 8.
MAXWELL, Robert, Esq., Surgeon, at Millport, Isle of Cumbrae, on March 19.
MORRISON, C. H., Esq., Surgeon, at Dumanway, County Cork, on March 14.
OLIVER, T. H., Esq., Surgeon, at Southdown, aged 92, on March 4.
RIBBON, G., M.D., at Kingstown, Dublin, on March 17.
RILEY, John, Esq., Surgeon, at Maidstone, Australia, aged 86, on December 18, 1864.
SIMPSON, T., M.D., at Old Calabar, on January 4.
WILLEY, Thomas, Esq., Surgeon, at Littlethorpe, Leicestershire, aged 41, on March 10.
WYNN. On March 22nd, aged 49, J. Teresa Elvira, wife of J. M. Wynn, M.D.

MR. JUSTICE WILLES, at York, thanked a medical witness for calling a black eye a black eye, instead of an ecchymosed one!

CONVERSAZIONE AT GUY'S HOSPITAL. On Tuesday last, a *conversazione* was given by the Treasurer of Guy's Hospital.

ROYAL COLLEGE OF SURGEONS. In future the museum, like the library, of the College of Surgeons will be kept open until five o'clock from March to August. Heretofore it has been closed at four o'clock.

APOTHECARIES' HALL. The Court of Master, Wardens, and Assistants of the society, have appointed Dr. William Perrin Brodribb secretary to the Court of Examiners, *vice* Alfred Mayor Randall, Esq., F.L.S., resigned.

CALCULOUS DISEASES are said to be almost unknown in the neighbourhood of the Moselle; but in other districts very frequent—in Upper Swabia, in the lime-districts of the Jura Mountains, in Dauphiny, etc.

THE LATE DR. J. DICKENSON. Professor Chevalier is, we hear, about to produce a biography of the late Dr. John Dickenson, who accompanied the missions of Oxford, Cambridge, and Durham, into Central Africa, and then perished in discharge of his duty.

THE ORDER OF THE BATH. The Queen has appointed to be Knights Commanders of the Most Honourable Order of the Bath, *inter alios*, J. B. Gibson, M.D., C.B., Director-General of the Army Medical Department; and W. Linton, M.D., C.B., Inspector-General of Hospitals.

THE LATE DR. FALCONER. Upwards of £1,000 have already been subscribed towards the proposed memorial of this gifted man of science. The proposed memorial will be a scholarship founded in connexion with the University of Edinburgh. A bust of Dr. Falconer will also be placed in the rooms of some London Society.

SIR RUTHERFORD ALCOCK, the late minister in Japan, served as surgeon with the British Legion in Spain, under Sir De Lacy Evans. He was successful on two occasions as Jacksonian Prizeman of the College of Surgeons. The subject of one prize was Concussion of the Brain; and of the other, Injuries of the Thorax, etc.

JERKED BEEF. At a meeting of the Commissioners of Sewers, Dr. Letheby said he had carefully examined the dried beef which is being brought from South America, and found that all the fat it contained was rancid; but with regard to the lean portion, although he had eaten none of it himself, he considered it was perfectly wholesome as human food.

AN INDIAN PHARMACOPOEIA. The sanction of Government authorities has been given to the publishing of a special Pharmacopoeia for India. The object is to call the attention of Indian medical officers to the indigenous plants and drugs of India. The carrying out of the work has been given to Mr. Waring, the author of a work on therapeutics. Sir Ranald Martin and other medical men in London have been formed into a committee to superintend the publication.

ASYLUM FOR IDIOTS. At the eighteenth annual festival of this institution, it was stated that the benefits were conferred upon 400 inmates of the asylum at Earlswood. Amongst other things taught were reading, writing, and reckoning. There was also a shop in the institution, at which buying and selling were carried-on, so that the children might be exercised in carrying on business. The estate, which belonged to the subscribers, was worth £50,000, and there was not a shilling owing. It was proposed to double the size of the asylum. The amount of subscriptions was about £2,000.

UNIVERSITY COLLEGE HOSPITAL. The annual report stated that during last year 28,000 sick poor had been relieved, and that the indoor patients had numbered 1,457, against 1,258 in the preceding year. The yearly expenditure of the charity was £6,936, of which only £3,000 is derived from fixed sources of income. Mr. E. Yates had bequeathed to the charity, in reversion, the residue of his estate, valued at about £40,000; and Mr. A. W. Jaffray had left a legacy of £2,000 free of duty.

THE ROYAL SOCIETY. The following are the names of the medical candidates for election into the Royal Society. A. L. Adams, M.B., A. Armstrong, M.D., W. Baird, M.D., J. C. Bucknill, M.D., Professor Robert Grant, W. A. Guy, M.B., G. Harley, M.D., B. Hobson, M.B., E. C. Johnson, M.D., Henry Letheby, M.B., W. A. Lewis, M.B., R. McDonnell, M.D., Charles Murchison, M.D., Sir J. P. Olliffe, M.D., C. B. Radcliffe, M.D., J. R. Reynolds, M.D., E. H. Sieveking, M.D., and A. T. H. Waters, M.D. There are fifty-three candidates of all classes; and only fifteen appointments inclusive of medical men to be made.

CONTAGIOUS DISEASES PREVENTION ACT. In the committee of supply in the House of Commons on March 24th, Mr. Ayrton complained of a sum of £5,000 being devoted to rendering the soldiers the great disservice of ministering to their immorality. He wished to know what towns were to benefit by this disreputable appropriation. Mr. Locke defended the vote, which he said was for the protection of the soldier. The Marquis of Hartington said the £5,000 would be spent principally in the wards of lock hospitals in several garrison towns; in erecting new lock hospitals where such wards could not be obtained, and specially at Aldershot for such a hospital. The vote was then agreed to.

CLOSE QUARTERS. It is calculated by the Registrar-General, allowing for increase of population since the Census, that the borough of Liverpool contains on an average 93 persons to an acre of ground, the city of Glasgow 84 persons, of Dublin 67, of Manchester 79, and the borough of Salford 21. The borough of Birmingham has 42 persons to the acre, the city of Edinburgh 39, of Bristol 34, the borough of Leeds 10. The metropolitan district (122 square miles) has an average rather below 39 persons to the acre. The ten towns together have an area of 219 square miles, and an average of 25,216 persons to a square mile. Placing a person on each square yard, 3,097,600 persons would occupy a square mile.

CHEMISTS' AND DRUGGISTS' BILL. On Wednesday last Sir F. Kelly moved that the Chemists' and Druggists' Bill be read the second time. He observed that the public had at present no protection whatever against unqualified persons carrying on the business of chemist and druggist, and this Bill enacted that hereafter persons commencing such business and compounding prescriptions shall be examined and passed by examiners under the Pharmacy Act, and be registered. He alluded to another bill, with the same title, introduced by Sir J. Shelley, which proposed that the examination should be made by a council of the trade, to be elected from the general body, and he stated his objections to this scheme of examination. Sir J. Shelley pointed out the distinctions between the two measures, and urged the greater advantage of placing the examination under the United Chemists' Society, instead of the Pharmaceutical Society, as regarded the interests of the trade, as well as those of the public. He suggested that both bills should be read the second time, and referred to the same select committee. Mr. Brady

supported the present bill, panegyrising the Pharmaceutical Society, and placing its pretensions in very favourable contrast with those of the Chemists' Society. Mr. Kinglake remarked that the Pharmaceutical Society had already a machinery for conducting examinations, whereas the Chemists' Society had none, and must create one. The bills were read a second time and referred to a select committee.

MEDICAL SOCIETY OF LONDON. The ninety-second anniversary meeting of this Society was held on March 8th. The following gentlemen were declared to be elected officers and Council for the ensuing year:—*President:* I. Baker Brown, Esq. *Vice-Presidents:* T. Davidson, M.D.; W. Harding, Esq.; G. D. Gibb, M.D.; and H. Smith, Esq. *Treasurer:* P. Marshall, Esq. *Librarian:* J. Palfrey, M.D. *Secretaries in Ordinary:* E. S. Thompson, M.D.; and E. A. Hart, Esq. *Secretary of Foreign Correspondence:* V. de Méric, Esq. *Council:* F. E. Anstie, M.D.; T. Bryant, Esq.; W. Camps, M.D.; W. Cholmeley, M.D.; R. P. Cotton, F.R.C.P.; W. J. Coulson, Esq.; R. Greenhalgh, M.D.; C. J. Hare, M.D.; C. H. Rogers-Harrison, Esq.; W. Harvey, Esq.; E. Head, M.D.; J. Jones, M.D.; A. Leared, M.D.; F. Mason, Esq.; H. P. Roberts, Esq.; W. R. Rogers, M.D.; W. Smiles, M.D.; W. A. Smith, M.D.; J. L. W. Thudichum, M.D.; J. Soelberg Wells, M.D. *Orator:* T. C. W. Cooke, Esq.

THE CASE OF DR. PRICHARD. The authorities in Glasgow have received a communication from Professor MacLagan, stating that antimony has been found abundantly in the liver, the spleen, intestines, and blood of the late Mrs. Pritchard. We believe we are correct in stating that steps are now in progress for committing the prisoner for trial. Our Glasgow correspondent says that the result of the analysis is looked upon as having given to the case a decidedly unfavourable aspect for the prisoner. With regard to the late Mrs. Taylor, the mother of Mrs. Pritchard, we believe the exhumation of her body is considered necessary, on account of an allegation that there was something peculiar about the registration of her death. It is said that, when the registrar applied to Dr. James Paterson, who attended Mrs. Taylor, he declined to give a certificate regarding the cause of death, at the same time intimating that he considered there was something in connexion with her decease which called for investigation. It is further stated, that Dr. Pritchard registered the death himself, and stated that deceased was seized with paralysis, and that an hour's attack of apoplexy supervened; whereas Mrs. Taylor's illness only lasted for four hours in all. (*Scotsman*.)

THE SANITY OF CRIMINAL LUNATICS. It may seem hard that those who are restored to comparative sanity should still be condemned to the darkest and most terrible of all dooms—that of perpetual incarceration in a madhouse—with the very worst class of maniacs. Yet this rule is necessary. There are several now in Broadmoor who years ago were only saved by accident from completing murder, and who afterwards passed two or three years in lunatic asylums. There in course of time quiet and careful medical treatment at last succeeded in restoring them to apparent sanity, and they were set at liberty. But the mind which seemed sane in the quiet good order of a well-regulated asylum, soon lost its balance when returned again to struggle with all the nervous excitements of the world. Some such who have been once liberated are now at Broadmoor—committed to its never-ending confinement, not for having attempted, but this time for having completed, sometimes one, sometimes more murders under circumstances of peculiar cunning and premeditation. Some

of these are still as bad as ever; some have been restored again to almost sanity for the second time. Neither will evermore be trusted at liberty. A commitment to Broadmoor for murderous madness is as final as regards the chances of return to the world as death itself.

THE MEDICO-PSYCHOLOGICAL SOCIETY OF PARIS, AND TOWNLEY. The *Derby Reporter* says: We last week inserted what we had reason to believe was a truthful statement respecting certain proceedings of the Medico-Psychological Society of Paris in reference to its opinion as to the mental state of G. V. Townley. We find, however, on the authority of Dr. Lockhart Robertson, the able editor of the *Journal of Mental Science*, and himself a member of the French Medico-Psychological Society, that we, in common with the entire provincial press, have been made the dupes of charlatanism, and the unconscious advertisers of an indirect falsehood. This gentleman alleges, in the most positive manner, that the Medico-Psychological Society has made no report; and therefore the communication which we had received from London in all good faith is a dishonourable ruse to bolster up a professional mistake, and to throw discredit on opinions given by such able and honest men as Drs. Bucknill, Hood, and Meyers. In order not to be entangled in the meshes of professional pique, and to justify us in the statements we have now made, we publish in full two letters by Dr. Lockhart Robertson, which appeared in the *BRITISH MEDICAL JOURNAL*.

CORK MEDICAL PROTECTIVE ASSOCIATION. The annual meeting of the County and City of Cork Medical Protective Association was held on the 16th inst., in the Royal Cork Institution; Dr. Harvey, President, in the chair. The following resolutions were unanimously adopted:—"That in conjunction with the metropolitan and other associations, we persevere in our efforts in impressing on the Executive and Legislature the justice of a retiring allowance or compensation to Poor-law medical officers, when incapacitated by old age or loss of health in the performance of their duties as public servants. That we value the expressed opinions of Poor-law Guardians, who, from their long experience in the working of the Medical Charities Act, deem less than £100 a year insufficient payment for the dispensary medical officers, and that we exercise every legitimate influence to insure this sum as the *minimum*. That we reiterate our conviction, that the Medical Council, under the Medical Reform Act, has failed in its duty to the profession and the public, in not prescribing, as they had power to do, a *maximum* standard of education for candidates about to enter the profession; and also for not taking more stringent measures to prevent the assumption of medical titles by unqualified persons. That it is much to be desired that some fixed principle on the part of the Army Medical Department, as to the rank and pay of medical officers, be adopted, so as to insure the best qualified men for appointments in her Majesty's service. That an approaching general election for members of Parliament will place in the hands of the profession (which is virtually unrepresented) a power to influence the several candidates to support in the House of Commons the legitimate claims of a body of men whose services to the public have been overlooked, and that we call on our brethren throughout the kingdom to exercise their franchise subject to this condition. That we feel deeply the valuable services rendered by the press of Ireland whenever the interests of the profession have called for its advocacy."

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TUESDAY.... Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.

WEDNESDAY.. St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.

THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.

FRIDAY..... Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

SATURDAY.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Medical Society of London, 8 P.M. Mr. Walter J. Coulson, "On Lithotripsy"; Dr. E. Day, "On Menstruation during Pregnancy";—Epidemiological Society, 8 P.M.—Entomological.

TUESDAY. Pathological Society of London, 8 P.M.

WEDNESDAY. Obstetrical Society of London, 7 P.M., Council Meeting, 8 P.M., Dr. Meadows, "Case of Moustrosity"; Mr. Truman, "Extrauterine Fœtation"; and other Papers.—Geological.

THURSDAY. Harveian Society of London, 8 P.M. Dr. Camps, "In what Class of Cases and under what Circumstances may we reasonably hope for Cure in Epilepsy."—Royal.—Chemical.—Linnæan.

FRIDAY. Western Medical and Surgical Society of London, 8 P.M. Practical Evening for the Narration of Cases and the Exhibition of Specimens.—Astronomical—Royal Institute.

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

DR. RICHARDSON'S papers will be continued in an early number.

THE PRESIDENT OF THE MEDICAL COUNCIL gives a *conversazione* at his house in Cavendish Square on April 5th.

BLISTERS IN RHEUMATISM.—The practice of applying blisters to the joints in acute rheumatism was, it is said, practised many years ago on a large scale at the Whitworth and Hardwicke Hospitals in Dublin.

THE ARMY MEDICAL EXAMINATIONS.—The highest number of marks, we are told, which can be obtained by army medical candidates, is 6900; not 6000, as was stated in this JOURNAL. The highest number obtainable at Chelsea, is 3400; and at Netley, 3500—making together 6900.

THE GRIFFIN TESTIMONIAL FUND.—Sir: The following subscriptions have been further received on behalf of the above Fund:—C. Spurgin, Esq. (Stratford St. Mary), 10s.; R. Slemman, Esq. (Tavistock), 5s.; H. T. Woodd, Esq. (Tavistock), per Mr. Slemman, 5s.; J. Pearce, Esq. (Tavistock), per Mr. Slemman, 5s.; W. C. Northey, Esq. (Tavistock), per Mr. Slemman, 5s.; R. Willis, Esq. (Tavistock), per Mr. Slemman, 5s.; J. G. Doidge, Esq. (Tavistock), per Mr. Slemman, 5s.; J. H. Willis, Esq. (Tavistock), per Mr. Slemman, 5s. From Lower Norwood, 5s.

Amount previously announced, £11s:10s:0. Received at the Lancet office, £7:17:6.

I am, etc.,

ROBERT FOWLER, M.D.,

Treasurer and Hon. Sec.

145, Bishopsgate Street Without, March 23th, 1865.

IRISH ARMY SURGEONS.—(F. P.)—The standard of general education required by the Dublin College of Surgeons, is lower than that of any other Examining Board in the United Kingdom. Of course, therefore, we may fairly conclude that the Irish medical candidates who are now flocking into the army are the worst educated, as regards general education, of all the candidates who apply for military honours. Whether a low style of general education is likely to advance the credit of our profession in the army, is a question which we will leave for the consideration of the Director-General and the Netley examiners.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following notice has been issued.

The Council of the Faculty have had the subject of *ad eundem* licences under consideration, and have resolved not to grant a diploma to any candidate who has not been examined and found qualified in all the branches of medical and surgical science comprehended in the curriculum of the Faculty. The circumstance of our *ad eundem* diploma having been granted, in a very few instances, to members of the Royal College of Surgeons of England who have not been examined on our full curriculum, arose from an inadvertent oversight. JAMES PATERSON, M.D.,

Faculty Hall, Glasgow, March 14th, 1865.

Registrar.

IODINE AS A PREVENTIVE OF SUPPURATION.—SIR: In your issue of March 11th, you state that M. Pétrequin has recently proposed a new method of preventing suppuration after the removal of tumours; namely, by means of the tincture of iodine. I beg to inform you that this method has for many years past been employed here by Mr. Spence, Professor of Surgery in the University. He has been in the practice of stating in his lectures, that he has sometimes, in amputations, used methylated spirits brushed over the flaps; and in cases where there have been abscesses in the soft parts included in the flaps, he has brushed the pyogenic surface—occasionally, even the whole surface of the flap—with strong tincture of iodine; this treatment being followed by decidedly beneficial effects.

Professor Spence, moreover, recommends in the case of chronic abscess requiring evacuation, that a free incision be made, and their inner surfaces painted with tincture of iodine. This treatment, practised in the Professor's wards in the Royal Infirmary, has been attended always with success, and is now invariably employed in cases of the above description. I am, etc.,

A PUPIL OF PROFESSOR SPENCE.

Edinburgh, March 15th, 1865.

[If our correspondent will again peruse the article to which he refers, he will see that we have not stated M. Pétrequin's idea to be *new*. It has no doubt arisen out of the known fact of the antipyogenic influence of iodine. But, if we understand our correspondent rightly, he tells us that Professor Spence uses iodine in cases where suppuration has already occurred, to retard the further formation of pus; whereas M. Pétrequin uses iodine to prevent suppuration altogether. EDITOR.]

COMMUNICATIONS have been received from:—PROFESSOR SIMPSON; DR. GILCHRIST; DR. DURANT; THE HON. SECRETARY OF THE HARVEIAN SOCIETY OF LONDON; DR. RADFORD; DR. JOHN THOMPSON; MR. H. E. NORRIS; DR. D. NORRIS; MR. CHRISTOPHER HEATH; DR. CRUISE; DR. HENDERSON; MR. SOUTHAM; AN OLD MEMBER; DR. DAVIS; THE HON. SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; MR. WINDSOR; DR. FREDERICK J. BROWN; DR. R. FOWLER; DR. DUCKWORTH; THE HONORARY SECRETARY OF THE OBSTETRICAL SOCIETY; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; MR. A. B. STEELE; DR. HUGH NORRIS; and MR. BROADBENT.

SUBSCRIPTIONS.

The following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

T. WATKIN WILLIAMS, *General Secretary.*

Birmingham, April 1865.

ADVERTISEMENTS.

8vo. with Coloured Lithographs and 48 Woodcuts, price 15s.

The Surgical Diseases of Children.

By J. COOPER FORSTER, Assistant-Surgeon to and Lecturer on Anatomy at Guy's Hospital, and Surgeon to the Royal Infirmary for Children.

London: LONGMAN & Co., Paternoster Row.

Just published, in fcap. cloth.

Druitt's Surgeon's Vade Mecum:

A MANUAL OF MODERN SURGERY. The Ninth Edition, thoroughly corrected, much enlarged, carefully brought up to the present time, and illustrated by 375 highly finished wood engravings.

London: HENRY RENSHAW, 356, Strand, and JOHN CHURCHILL and SONS, New Burlington Street.

Weiss's Illustrated Catalogue,

containing nearly 800 engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price, 6s. 62, Strand, London.

"This catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced, and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour which we are glad to see strictly observed in this catalogue."—*Lancet*, September 12th, 1863.

Death Vacancy for immediate

transfer, with Succession to a good Middle Class Practice in a large Market Town. The average on bills sent out for the last three years was £132 per annum; and there is every likelihood of obtaining an Union Appointment worth £100 per Annum.—Address H. P. L. Bourne, N. Devon.

Resident Clinical Assistants.—

A VACANCY Having occurred in the HOSPITAL for CONSUMPTION and Diseases of the Chest, three Gentlemen who are desirous of becoming Candidates for the vacant office are requested to send in their applications, with testimonials, on or before MONDAY, the 10th of April, and to attend the Medical Committee on the following day, at 4 o'clock. Testimonials as to moral character as well as to medical qualifications are required. Further particulars may be obtained at the Hospital.

Brompton, March 29th, 1865.

PHILIP ROSE, Hon. Sec.
HENRY DOBBIN, Sec.

Classical and Mathematical.—

Dr. STEGGALL prepares Gentlemen for their Examinations in Classics and Mathematics at all the Medical Boards, viz., the Preliminary Examination at Apothecaries' Hall; the Matriculation Examination of the London University; Preliminary and Fellowship Examination at the Royal College of Surgeons, etc.

Dr. STEGGALL continues his instruction for all Medical and Surgical Examinations during the summer months.—Address DR. STEGGALL, 2, Southampton Street, Bloomsbury Square, London.

ESTABLISHED 1848.

Mr. J. Baxter Langley, M.R.C.S.
Eng. (late of King's College, London), PROFESSIONAL AGENCY, 50, Lincoln's Inn Fields, W.C.

Competent Assistants provided

without delay, free of expense to the Principals. No gentlemen recommended whose antecedents have not been inquired into. Apply to Mr. Langley, 50, Lincoln's Inn Fields, W.C.

Locum Tenens can be despatched

by an early train, after receipt of letter or telegram, stating terms, duties, and qualifications required.—Fee, 10s. 6d. Address Mr. Langley, as above.

In a good Market Town.—For

Transfer, in a prosperous town, containing 10,000 inhabitants, with a populous district around, a well established General Practice. Average receipts £500 a year; present year about £600. Capable of immediate increase, as the holder has declined midwifery. Appointments £180. Excellent family residence, with large garden, stables, etc.; rent £42. Family reasons for leaving. Efficient introduction. Address "S. 1055," Mr. Langley, as above.

Partnership. — In a thriving

Town in Hants, within 40 miles of London, there is an opening for a well qualified gentleman to join a well established professional connexion, from which one of the Partners is retiring. Income upwards of £800 a year. House rent £45. Furniture optional. The opening secures a certain income of £100 a year. Address "S. 1130," Mr. Langley, as above.

Devonshire.—In a good Market

town, in one of the healthiest localities in England, in a district enjoying the sea breeze, a genuine Family Practice, with high-class patients. No parochial appointment. Dispense, but charges for visits only. Midwifery fees from £1 1s. to £5 5s. Average receipts for the last three years, £600. Expenses small, one horse only being required. Twelve months introduction, if required. Address "S. 1131," Mr. Langley, as above.

Society for Relief of Widows

AND ORPHANS OF MEDICAL MEN. Instituted 1788. Incorporated by Royal Charter, 1864. The SEVENTY-SEVENTH ANNIVERSARY DINNER of this Society will take place on Wednesday, April 26th, at the Albion Tavern, Aldersgate Street.

MARTIN WARE, Esq. (President), in the Chair.

Tickets. One Guinea each, to be obtained from the Stewards, from the Secretary, or at the Tavern. Dinner to be on table at half-past Six o'clock precisely.

Any registered Member of the Medical Profession residing in the County of Middlesex, or within the limits of the London District Post, is eligible as a Member of the Society, at a Subscription of Two Guineas a year. Widows and Orphans of Members of not less than two years standing are eligible for relief, and to such applicants relief was granted last year to above £2150.

S. W. J. MERRIMAN, M.D., Secretary.

53, Berners Street, W.

National Orthopædic Hospital,

GREAT PORTLAND STREET, REGENT'S PARK.
Consulting Physician—H. GUENEAU DE MUSSY, Esq., M.D., 4, Cavendish Place, Cavendish Square.

Consulting Surgeon—HOLMES COOTE, Esq., 13, Queen Anne Street, Cavendish Square.

SURGEONS.

T. CARR JACKSON, Esq., 3, Weymouth Street, Portland Place.
HENRY DICK, Esq., M.D., 59, Wimpole Street, Cavendish Square.
LOUIS STROMMEYER LITTLE, Esq., 31, Brook Street, W., and 2 West Street, Finsbury.

The Surgeons attend daily at 2 p.m. Operations, Tuesday, 2 p.m. Lectures on the Pathology and Treatment of Deformities will be given during the year by the Surgeons in rotation. The Practice of the Hospital is open to all members of the profession and Students of Medicine.

Bass's East India Pale Ale.—

BARCLAY'S PORTER AND STOUT.
In 16-Gallon Casks, Bottles, Half-bottles and Imperial Pints.
Also DEVONSHIRE CIDER.
BERRY BROS., & CO., 3, St. James's Street, London, S.W.

A Description

OF THE

MODE OF TREATING CONSTITUTIONAL SYPHILIS BY SYPHILISATION: AND ITS RESULTS.

BY

PROFESSOR W. BOECK, M.D.,
CHRISTIANIA.

If space can be given me in this JOURNAL, I will take the liberty of briefly describing the process of syphilisation, and state the results which I have observed up to the present time.

I feel the more called upon to take this step, as I perceive, by Mr. Lee's letter in the JOURNAL of February 18th, that medical men in England are totally unacquainted with the whole proceeding. I know nothing of Mr. Lee's own experience in syphilisation, and possibly he has not tried it; but he says that Dr. Marston has informed him that he has lately carried it to the extent of forty to sixty inoculations without any satisfactory result. From these words, it is evident that Mr. Lee has not studied the principles of syphilisation. What Dr. Marston has done has been simply to inoculate a few times with syphilitic matter; but inoculation is not entitled to the name of syphilisation unless it be continued until the syphilitic matter will no longer take. It is necessary to continue inoculating as long as the virus has any visible effect on the system. Mr. Lee will perhaps answer, that the virus never ceases to have a visible effect, for this assertion has been made by some; but I know for certain that it does, having myself observed such to be the case in every one of the seven or eight hundred patients whom I have had under treatment.

The virus seldom loses its power on the system earlier than at the end of three months, and seldom later than at the end of four months and a half. However, after the lapse of some time, it will be possible, by inoculating with syphilitic matter, to produce on the patient a pustule or a sore; and in proportion to the time which has elapsed after syphilisation, a greater or less number of pustules can be produced; but these pustules and sores are never so large, and it will never be possible to produce such a series of inoculations as take place during the first syphilisation.

With regard to the syphilitic virus, the body never returns to the state in which it was before syphilisation. And here lies the turning-point or gist of the whole matter. Here we discover the striking analogy between syphilisation and vaccination. From this point of view the matter must be considered; and when syphilisation has been practised in strict conformity with this theory, the same astonishing results will be seen which for a long course of years I have been able to produce by this method. But people have not cared to consider the matter in this light. The French Academy knocked syphilisation in the head without knowing practically anything about it; and everybody has blindly followed the French Academy. The whole affair has been considered as a chimera. What I am most surprised at is,

that practical Englishmen should have allowed themselves to be led away by mere words, instead of examining the hard facts for themselves.

Mode of Syphilisation. In syphilising, I take matter from an indurated chancre, and inoculate each side of the chest with three different punctures. After the lapse of three days, I take matter from the pustules which by that time have made their appearance, and inoculate the sides also with three different punctures on each side, always extracting matter from the last matured pustule for the next inoculation, until this matter no longer takes on the sides. I then extract matter from the sides, and in the same manner as before inoculate the arms, where it again takes for a few successive times; and proceed in the same manner as before on the sides. When it ceases to have any effect on this part, I take the matter from another patient under treatment for syphilisation. This matter will take for a few successive times; and with it I inoculate the sides of the chest and the arms at the same time. When this matter (from the other patient) loses its effect on these parts of the body, I transfer the matter from the arms to the thighs, where it again will take for a few successive times; and, when it no longer produces a satisfactory result, I introduce new matter extracted as before from another patient under treatment for syphilis with syphilisation. I now continue on the thighs until the matter becomes inoperative. When the virus ceases to have any effect on the thighs, the patient will either be cured, or every symptom of the disease will in a short time vanish. One or two mucous tubercles will sometimes remain, or an exudation in the throat, etc.; but these soon disappear on the application of caustics.

With regard to the mode of inoculation, it is necessary to be careful to make every group of punctures at some distance from the one previously made; otherwise large confluent sores may result. I would likewise draw particular attention to the necessity of first inoculating on the sides, as chancres on this part of the body are seldom large, and have never, in the course of my experience, become phagedenic. If we begin with the thighs, the chancres will be large, and may possibly become phagedenic, and leave a bad cicatrix. If we finish with the thighs, susceptibility will to a great extent have ceased to exist, and the sores which then arise will neither be large nor deep.

The different degrees of development which we observe chancres to reach on the different parts of the body, according to the part which has been first inoculated, must be the surest proof that syphilisation does not only act locally, but also produces absorption into the system; and that the whole body is influenced by this treatment.

Syphilisation must be adopted in cases of *Constitutional Syphilis* only, it being often difficult or impossible to tell whether constitutional syphilis will follow a chancre; and syphilisation ought to be adopted chiefly or only when mercury has not been previously given. Even after mercurial treatment, syphilisation is certainly the best method that can be followed; but in that case there will not unfrequently be a relapse; and as long as the doctrine of syphilisation meets with such strong opposition, the mercurial treatment previously adopted is liable to be forgotten, and the cause of the relapse to be assigned to syphilisation. In fact, syphilisation must be the first method resorted to in constitutional syphilis, and not the last.

Results of Syphilisation. I will now state the results of syphilisation as practised by me in my public ward in the hospital in Christiania. From October 1852 to the end of February 1865 there have been 502

patients subjected to the treatment of syphilisation, of which number 429 had not been under mercurial treatment. Of these latter number, 38½ were cured completely, and 45 have returned to the hospital with a relapse, 28 of whom were not subjected to any new constitutional treatment. In these, external remedies have been alone applied, and in the greatest number of cases only for a few days. Thirteen of the forty-five were resyphilised; and four of them were treated with iodide of potassium.

Of the 429 there were 42 children suffering from hereditary syphilis. Many of these had atrophy; but I wished to see to what extent syphilisation might be practised. Of these 42 children, 22 died. This may perhaps be considered a high rate of mortality; but whoever knows anything of the treatment of hereditary syphilis in new-born children will not find this result unsatisfactory. Moreover, of the aforesaid 429 individuals, one child, who was suffering from acquired syphilis, died of croup, and a woman, aged forty, of dysentery. The state of the patients' health after treatment has been most satisfactory. Apoplexy, paralysis, and the numerous internal affections, which are an every day occurrence after mercurial treatment, have never, as far as my experience goes, followed syphilisation. Tertiary symptoms have been confined to slightly developed affections of the bones; and of these cases I have seen four.

In my private practice I have had at least 250 persons under treatment, who, whilst the treatment was proceeding, were able to transact their daily business. The results of syphilisation in my private practice have been still better than in the hospital, these patients having been in easier circumstances. But as their case did not come under the observation of any one but myself, I will say no more regarding them.

If the results of syphilisation be compared with those of mercurial treatment, the difference will be found so extraordinary that the most zealous advocates of the latter must yield their opinion to the force of facts. There is, however, one point in which these two modes of treatment do not differ so widely; and that is, with respect to their several results upon the offspring.

The effect of mercurial treatment on the offspring has long been known. It is acknowledged as a fact that, when the mother has been treated for syphilis with mercury, the first children have been either in a state of putrefaction, or still-born or syphilitic; and there is no certainty that she will ever give birth to healthy children. I have, however, shown, in my statistical work entitled *Recherches sur la Syphilis* (Christiania, 1862), that when a female patient has been treated for syphilis previously to the age of puberty, she almost always gives birth to healthy children. If a male patient have been treated for constitutional syphilis with mercury, his children will generally be healthy. With but very few exceptions, they will be free from the disease; and even with the exceptions, they will not have it in so high a degree as those born of a mother who has been syphilitic. With regard to syphilisation the case is similar; but my experience, which on this subject is not trifling, would seem to justify the idea that the mother sooner begins to have healthy children after syphilisation than when the parent has been subjected to mercurial treatment; and if a mother, after syphilisation, has given birth to a healthy child, the children born afterwards will not be syphilitic, which they sometimes are after mercurial treatment.

An attempt has been made to throw obstacles in the way of syphilisation by pointing to its results where children are concerned, and alleging its inferiority in such cases to mercurial treatment. It has also been attempted to prove that so-called "deriva-

tion" is not a cause of disease in the offspring; but this is not true, for the case is precisely the same after derivation as after syphilisation.

I have now given a brief description of syphilisation as I practise it, and its results; and it would be indeed gratifying to me if its vast superiority over the mercurial system were to be recognised; and, if this is ever to be recognised anywhere, it must be by the most practical of all nations. With regard to syphilisation, there are many trifling points to be noticed, in order that the different stages of the process may follow with regularity, and produce the desired result. By long experience I have learned that, wherever syphilisation has been tried, it has been rejected on account of inability to surmount the small impediments connected with the system.

It has been asked in what way syphilisation acts on the system; and I must confess that I do not know. The results are plain enough; but how they are brought about I am unable to explain. But do we know more of vaccination and of many other great facts in the science of medicine? It is easy to construct a theory; and it would be strange if I had not formed one after having practised this method for nearly thirteen years; but it will make little difference to me if my theory should be proved a false one, for the facts will remain as strong as ever.

I consider syphilis to be a disease which has to go through a certain cycle. We often see that it vanishes when left to take its own course; but we are unable to say how often at a later date it may return. I think that all I can say with certainty is, that relapses after the "expectative method" are less frequent than after the use of mercury. I have shown, in my statistical work above referred to, that no treatment is followed by so many relapses and gives generally such bad results as the mercurial. The reason of this, I believe to be very simple. Mercury interrupts the cycle which the disease has to pass through; it is not able to break out on the skin and the mucous membranes, and it consequently attacks other organs at a later period. By means of syphilisation, syphilis is made to pass through an artificially produced cycle; the course of nature is not interrupted, but, on the other hand, assisted, and sometimes hastened.

In the course of my practice, I have been compelled, by childbirth or some other illness, to stop syphilisation; and, in such cases, relapses have often occurred. The cycle which has commenced is interrupted; and this, I believe, often happens when the disease is left to take its own course; for, during the time that the disease will have taken to pass through its several stages, many circumstances may arise to produce an injurious effect.

I will say no more of my theory. What I have written is essentially practical. What we have to look to in this case are facts. There will be plenty of time for disputation when the main point is settled.

If fifty patients in one of the London hospitals, suffering from constitutional syphilis, were placed under my treatment, I would show that what I have stated is in conformity with nature. I only request that five gentlemen should be appointed to watch my mode of treatment; and whether they be advocates of, or opponents to, the system, would be immaterial to me.

SANITARY REFORM. Sunday, March 12th, was by agreement appropriated by many of the clergy of New York to sermons relating to the unhealthy condition of that city, and the duty of taking vigorous methods for its improvement.

Observations

ON THE

CÆSAREAN SECTION AND ON OTHER OBSTETRIC OPERATIONS.

BY

THOMAS RADFORD, M.D.,

F.R.C.P. EDIN. AND F.R.C.S. ENG., ETC.,

HONORARY CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL,
MANCHESTER.

CHAPTER VII.

The Means of Delivery by Destructive Operations.

I.—*The Induction of Abortion.* The induction of abortion has been proposed for the purpose of superseding the necessity of the Cæsarean section; but, in general, the woman has passed the period when it could be advantageously performed. In the great majority of such cases, she has arrived at the full period of pregnancy, and in many cases labour has actually commenced before the obstetrician has become acquainted with the malconformation of the pelvis. Sometimes he becomes acquainted with the pelvic deformity from the difficulty he has experienced in a former labour. It occasionally occurs, although very seldom, that the presumptive evidence of a malformed pelvis may be so strikingly observable in the early months of a first pregnancy as to induce the woman or her friends to apply to an obstetrician. But tumours of different kinds and exostosis may exist in the pelvis, without affording any indications whatever which might lead to a suspicion of their existence.

Whenever it is ascertained, after a most careful investigation in a first pregnancy, that the pelvic capacity is either positively or relatively too small to permit a viable infant to pass, then it would be justifiable, if possible, to perform this operation. But, if the woman again become pregnant, a question arises, whether it is justifiable again to adopt this plan. My opinion (which I submit with great deference to the profession) is, that it ought not a second time to be performed. If such a practice be admitted as sound, it establishes a principle totally at variance with the laws of God and man. The remarks to be made hereafter on the comparative value of maternal and fetal life will, I hope, be fully considered before such steps are a second time followed.

It has been remarked, that some teachers of midwifery in this country have asserted that this operation should be only once performed, after which the wretched woman should be left to take the fearful chance of the Cæsarean section. To say this, was to assume the position of the Supreme Judge. Just as well we ought to cure syphilis once only. It is said to be "a moral dogma, absurd and immoral, to prefer an ovum of four or five months, dependent for its existence on the mother." I shall not attempt to refute these remarks; but, after I have fully put my opinions before the profession, I shall content myself to leave the subject in their

hands, with a desire that they will carefully weigh all the contingent circumstances, and consider whether there is any validity in my observations.

It is not on moral grounds alone that I object to the induction of abortion in order to supersede (as it is said) the Cæsarean section. It is not so safe an operation as it is usually represented. On the contrary, sometimes great danger has succeeded, and in some cases even death has ensued. Great difficulty has frequently been experienced in its performance, and in some cases it could not be accomplished. When the pelvis is highly distorted by mollities ossium, its entire character is changed; its cavity becomes altered in its shape, and all its diameters are very much diminished, whilst the depth anteriorly is very considerably increased. The position of the viscera which are normally contained within the pelvis is changed according to the degree of distortion. The uterus is especially altered in its relative position; it stands obliquely above the brim; and, in most cases of extreme deformity, the os uteri cannot be felt. (See preceding remarks.) Under such circumstances, it is utterly impossible to perform this operation; and, in many cases, great risk is incurred by making the attempt. It is true that, by rash and rude manoeuvres, so much mischief may be done that the expulsion of the ovum follows, although there has been no direct entrance into the os uteri, but solely in consequence of the injury inflicted upon the uterus or upon some contiguous organs, which is succeeded by great constitutional irritation, fever, etc., and sometimes by death. An experienced practitioner unsuccessfully attempted to destroy the ovum. The woman died from the effects. The pelvis is in my possession, and is an example of very great distortion from mollities ossium. Similar cases are also elsewhere recorded. In pelvis distorted from the effects of rickets, in which the brim is elliptical, and the cavity and outlet comparatively more capacious, the difficulties above mentioned would be found considerably less.

I may be told that the difficulties and risks of attempting to induce abortion by passing an instrument through the os uteri, for the purpose of destroying the ovum, may be almost altogether avoided by the employment of the douche. From all the information which I have been able to obtain upon this subject, this measure has very frequently failed to produce any effect when employed in the early months of pregnancy.

II.—*Craniotomy.* Craniotomy is recognised in these kingdoms as an operation of election, and is most extensively and frequently performed. It is employed in those cases of difficult labours in which the women cannot be delivered by the forceps, long or short, by the vectis, or by turning. It is also often had recourse to in many contingent accidents which happen during parturition, as in some cases of accidental and unavoidable hæmorrhage, in some cases of convulsions, in some cases of rupture of the uterus, and also in those cases of protracted labours in which, from the neglect or ignorance of the practitioner, the pelvic organs and tissues are brought into such a state from pressure as to render delivery by other means hazardous to the life of the woman.

It has been proposed in cases of osseous deposits in the pelvis, on the grounds that it is impossible to estimate their density, and that most likely the structure would yield or even break down under the

pressure made upon it during the extraction of the reduced head. This is, however, an unwise proposition, and ought not to be entertained upon such a presumption alone.

Now, when we contemplate the aggregate amount of infants destroyed by craniotomy in these countries for one year, the thought must be truly appalling. The facts of such a case cannot be, unfortunately, accurately arrived at. Reports of lying-in hospitals may in some degree show the force of this remark. Dr. Collins reports that, during his mastership at the Dublin Lying-in Hospital, 16,414 women were delivered, during which time craniotomy was performed in seventy-nine cases. Dr. Joseph Clarke reports that, in 10,387 cases of labour, craniotomy had been performed forty-nine times.

Now, assuming, in the first place, that craniotomy was performed relatively as frequently in the aggregate amount of labours in England and Wales which occurred in one year, as it was under Dr. Clarke's management in the aggregate of his cases, we should have $2,831\frac{1}{2}$ infants annually destroyed by this operation: and, by making a similar relative computation of Dr. Collins's cases, there would be $2,887\frac{3}{4}$ infants destroyed in one year. But, if a true statement could be obtained of the number of craniotomy operations which are annually performed in these kingdoms, the aggregate amount would far exceed either those of Dr. Clarke or those of Dr. Collins.

As it is so difficult—nay, I would say, quite impossible—to ascertain with arithmetical accuracy the real condition of the apertures and the cavity of the pelvis, we ought, in all cases of slighter degrees of distortion, as far as possible, to endeavour to save the infant, by first making a cautious and judicious trial of the forceps or turning, before we have recourse to craniotomy.

Then, as we have craniotomy performed in all cases in which the pelvic apertures or its cavity are either relatively or positively diminished, so as not to allow delivery by other means; as we know that most of the obstructing causes to labours progressively increase in size,—it must be evident that craniotomy must be much more difficult and dangerous to perform in some cases than it is in others. On this account, I shall treat of it under two heads.

The first division includes those cases in which there is relatively no very great disproportion between the pelvic measurements and those of the head of the infant. In some of these cases, the mere perforation of the skull will suffice to set it free. In others, it will also be necessary to break up the brain, and then either partially or entirely to remove it from the cranial cavity; after which, it may be expelled by the uterus, or drawn out by the hand alone, or by the aid of the crotchet, or by that of the craniotomy-forceps.

The second division embraces those cases in which there is relatively greater disproportion between the pelvis and the infant's head. There is, however, even in these cases, more difficulty experienced, and more danger attending the operation, in some than is found in others.

The pelvis may be distorted by malacosteon or rickets, or its cavity may be so much diminished by exostosis or tumours that a question may arise whether a mutilated child can pass through it. The opinions of different writers vary as to the space necessary to exist in the pelvis in order that a crani-

otomised infant can be dragged through it. Some state that a free space of one inch and a half in the antero-posterior diameter of the pelvis is quite sufficient; others say an inch and three-quarters is required; whilst others, again, affirm that, unless there be a space equal to two inches in this diameter, a mutilated infant cannot be drawn through the pelvis. One writer, however, has had the boldness to declare that he has delivered a woman when there was only one inch and a quarter space in the antero-posterior diameter.

These discrepancies of opinion as to the required space for crotchet-delivery are difficult to understand; but the different characters which pelves assume may in a measure account for them. But there has, doubtless, been some mistake made in either the accuracy of the measurement or in the age and development of the infant, as it is quite impossible to deliver a full-grown infant when such a contraction of the pelvis exists as the minimum above mentioned. There is an unchangeable mechanical law which cannot be averted in these cases; that is, a body of a definite or given size cannot be drawn through an opening whose diameters are less than itself. Then, in order to reduce the infant's head, the vaulted part of it must be removed by taking away the two parietal and the frontal bones. Dr. Osborne reduced the head of the infant as far as possible, and then placed the base in (as he thought) the most favourable position by turning it so as to bring it sideways first through the pelvis. He succeeded after great efforts, and delivered the woman, whose pelvis measured at the brim, in its antero-posterior diameter, only (as he says) one inch and a half. Dr. Osborne was doubtless mistaken in his conclusions, which has been so ably and clearly proved by Dr. Hull and Dr. A. Hamilton.

The measurement of the side of the base of the skull corresponds with Dr. Osborne's estimation of it; but, in his anxiety to astonish the profession, and to prove his great achievement, he overlooked the fact that the other side of the head had to follow; and that the bulk must, therefore, be necessarily greatly increased by the addition of the cervical vertebræ and the soft part of the infant's neck, which must lie upon it and pass at the same time.

Now Dr. Hull has experimentally and indisputably proved the fallacy of this assertion; and has shown that the least measurement of the head, when it has been reduced to the utmost, after dragging away the frontal and the two parietal bones, is from the root of the nose to the chin; and, therefore, in order to bring the head (after craniotomy) through the smallest possible pelvic space, the face must be brought first. Dr. Hull, in Plate xii, Fig. 1 (*Observations*, etc.), gives a representation of the reduced head, placed over a sketch of the brim of a distorted pelvis; as well as the outline of that of Eliz. Sherwood. So that, in such cases, it is most desirable to convert the case from a vertex, if that were the original presentation, to a face case. After this change has been accomplished, the crotchet should be fixed in that situation, so as to turn the chin towards the pubes; and the extractive force should be directed so as to draw down and keep the chin in the anterior part of the pelvis, as the natural flexion of the head with the vertebræ facilitates the passage of the chin under the arch of the pubes. Great care should be taken to prevent injury being

done to the uterus or the vagina by the sharp edges or points of the bones of the skull, by placing over them the scalp-integuments.

Dr. Davis says the necessity for Cæsarean section may be reduced to zero by craniotomy; and, using his osteotomist, he asserts that he has succeeded in bringing the reduced skull of the infant through the space existing in the pelvis of Elizabeth Thompson.

This operation was undertaken on a block of wood, in which the pelvis was carved, etc. I had (now in St. Mary's Hospital) similar blocks; but I could never accomplish the extraction. However, it is one thing to operate on an inanimate machine, however accurately formed, and another to operate in the pelvis of a living woman. I had different preparations made of the base of the cranium, with the vertebrae lying over the side and over the occiput, to show their relative measurement to the brims of different sized pelves, which were cut in wood.

But a practical question suggests itself: Will the performance of craniotomy meet all the difficulties arising from distortions of the pelvis? or can a woman be delivered by this operation, however greatly contracted the brim of the pelvis may be? Notwithstanding the great reduction which may be made in the head of the infant, and however favourably its base may be placed, I most unhesitatingly assert that it is sometimes utterly impossible by any means whatever, either by the use of the osteotomist or of the cephalotribe, to deliver the woman. We ought never to disguise from ourselves that, in a great number of cases of extreme distortion, it is not possible to attempt delivery, as neither the os uteri nor the presentation of the infant can possibly be felt. This was found to be the case in many of the women whose cases are tabulated. (*Vide* remarks on the necessity.)

But, in many cases in which this information has been obtained, the head of the infant has been opened, and in some instances it has been reduced to its utmost limits, and yet the practitioner has been unable to drag it through the pelvis. Dr. Hull states in his *Defence* (p. 222) that ten women, upon whom embryulcia had been performed, lost their lives. He also relates three other cases, in which both the mothers and the infants perished. In one, neither the os uteri nor presentation could be reached; the uterus ruptured, and the infant escaped into the abdominal cavity. In another, after great difficulty, the breech was found to present. An attempt was made to pass the hand to lay hold of this part; but it failed, on account of the great pelvic contraction. After a second trial, the blunt hook was with great difficulty fixed; but, "notwithstanding all my exertions, the presentation could not be brought lower than the brim of the pelvis." She, therefore, died undelivered. In the third case, Ellen Gyte, who had been in labour sixty hours, the head was opened, and the crotchet applied; but, after the most strenuous exertions, it could not be brought through the pelvis. The vagina ruptured, and the infant escaped into the abdominal cavity. The pelvis was highly distorted; the diameter of the largest circle that could be formed in the superior aperture was two inches and one-twelfth. The pelvis now belongs to me.

In a case in which the pelvis was highly distorted, under the care of the late Mr. R—, the head was perforated; but, after the most powerful efforts, he was unable to bring it down. The uterus ruptured,

and the child escaped into the abdomen. She died undelivered. A cast of the pelvis is in my possession. The cause of distortion in all these cases was mollities ossium. I have known several other cases in which the same melancholy events happened; and doubtless, if the grave could unfold the mysteries contained within it, very many more horrible terminations of pregnancy would be brought to light.

But, even granting that, in some extreme cases of distortion, there may exist sufficient pelvic space to permit an infant, whose head has been reduced to the utmost, to be dragged by great force through the pelvis, yet it must not be forgotten that such an operation must be extremely hazardous to the life of the mother. It is one thing to deliver the woman, and another to do so safely. It is much to be deplored, that this operation is still permitted to be so unconditionally performed; especially so when the injuries which are frequently inflicted on the pelvic organs, and when its comparative mortality, are considered.

The statistics of craniotomy are in a very unsatisfactory state. After a very minute search, I have been quite unable to draw out such tables as I wished. Feeling strongly the importance of deductions which are to be drawn from an accumulation of well authenticated facts, I published a letter (*Provincial Medical and Surgical Journal*, vol. xviii, p. 494, 1849) requesting that the members of the Association would transmit me a statement of all the cases which had happened in each of their practices; but my appeal did not elicit much information. Not having been successful in this attempt, I could only avail myself of the statements already published by my worthy and esteemed friend Dr. Churchill of Dublin, in his *Theory and Practice of Midwifery*. The following is a copy of his tables.

Authors.	No. of cases.	Mothers died.
Dr. Smellie	44	4
Mr. Perfect	3	0
Dr. Joseph Clarke	49	16
Dr. Granville	3	3
Dr. Ramsbotham	34	5
Dr. Maunsell	5	2

Or about 1 in 5.

"Independently of the abuse of this operation (craniotomy)—of its unjustifiable frequency—let us for a moment look at its relative fatality, when compared with the Cæsarean section.

"According to the above" (Dr. Churchill's) "statistics, British practitioners resort to craniotomy once in 219 cases; the French, once in 1,205 $\frac{2}{3}$ cases; the Germans, once in 1,944 $\frac{1}{3}$. The average, therefore, of these three nations, will be one in 896 $\frac{1}{3}$. In 252 cases, 50 mothers died, or about one in every five. As regards the Cæsarean section, the same author states that he has collected 321 operations since 1750, from which 149 mothers recovered; and in 187 cases, where the result is mentioned, 130 children were saved, and 57 lost.

"Hence, then, we have a calculation showing that in craniotomy, where of necessity all the children must be sacrificed, one woman out of every five died; while, in the Cæsaean section, one mother recovered out of two and a fraction, and the success to the child was certainly most fortunate."

The destruction by craniotomy of a number of infants in different women, in successive labours, both in the practice of other obstetricians, as well as those which happened to myself; the ignorant and groundless adoption of this operation: the unprofessional and disgraceful manner in which I have known it performed (in one case, the head was opened by a pair of scissors, which were obtained from some part of the family; in another case, by a penknife); and the operation being frequently performed without a consultation,—these circumstances, and deep reflection on the social and moral right to destroy life, convinced me that the present recognised practice in these cases ought to be modified.

In a course of lectures delivered to the members of the profession, I strongly denounced craniotomy as an operation of election; and I recommended it to be performed generally as an operation of necessity, and that it should only be conditionally accepted as one of election. These opinions I then expressed, and have ever since advocated and in every way promulgated. (*Provincial Medical and Surgical Journal, and British Obstetric Record, etc.*)

Such, then, was my proposition in 1843; and now, in 1865, after long reflection and matured experience, I am, if possible, more strengthened in my convictions. The remarks of Dr. Bedford, which I afterwards found in his translation of Chailly, bear so forcibly upon the subject, that I do not hesitate to quote them. He says:

"The Cæsaean section is undoubtedly a dread alternative for the accoucheur to choose; but I cannot agree with Dr. Chailly, that its fatality is so great as he represents; nor am I disposed to adopt the opinion (unfortunately too general) that craniotomy is always to be preferred to the Cæsaean section. In truth, it needs some nerve, and, for a man of high moral feeling, much evidence as to the necessity of the operation, before he can bring himself to the perpetration of an act which requires, for his own peace of mind, the fullest justification. The man who would wantonly thrust an instrument of death into the brain of a living foetus would not scruple, under the mantle of night, to use the stiletto of the assassin; yet how often has the foetus been recklessly torn from its mother's womb piecemeal, and its fragments held up to the contemplation of the astonished and ignorant spectators as a testimony undoubted of the operator's skill. Oh! could the grave speak, how eloquent, how momentous, how damning to the character of those who speculate in human life, would be its revelations!"

The facility of its performance has led to its abuse. Its recognition in the British obstetric code reflects no credit on the country, especially when its frequent performance is compared with the practice in France and Germany. It cannot be denied that craniotomy is a cruel operation; for surely no obstetrician ought to be so ignorant as to suppose that the infant *in utero* is void of sensibility. Yet there are some parties (if judged by their estimate of its life) who either professedly or actually believe it does not feel. This is, however, either a moral or a physiological

fallacy; for there is not a doubt that it is endowed with this faculty in a very eminent degree, and consequently it must endure great bodily suffering from this practice. There are some practitioners who admit the existence of this principle; and, with the view of avoiding the infliction of pain caused by the perforator, delay opening the head until after its death. Craniotomy and embryotomy are the only operations which are recognised and justified by the British profession for the purpose of destroying life; but, although they are admitted into our obstetric code, they are not to be found in that of the law, and are only sanctioned by custom, and, through this usage, considered as "justifiable homicide".

There is no difficulty in understanding why so low an estimate of foetal life is entertained, when we consider what the doctrine is which is taught *in cathedrâ* and *extra cathedram*—"that, to save the life of the mother, it is justifiable to destroy the infant." From the early inculcation of this principle, the student becomes hardened to the performance of this dreadful task, and does it without compunction, and, no doubt, sometimes without reflection. My experience warrants me to make the above declaration, having met with many cases in which this operation has been most unnecessarily, and in some cases has been most unprofessionally, nay, most unjustifiably, performed.

Having now very fully expressed my objections to the recognition of craniotomy as an operation of election, I shall proceed to state my opinion in what cases it might be considered right to perform it.

When the infant is ascertained by the stethoscope to be dead, and the time for delivery has arrived, then craniotomy is justifiable; but the labour ought never to proceed a moment longer after delivery is required, in expectation of this event happening. The destruction of the infant from procastination differs very little in principle from taking its life by the perforator; and, therefore, timely and other appropriate measures should be employed to prevent this event. Such are the long and short forceps, turning, and the Cæsaean section.

When some serious accident happens, such as rupture of the uterus, it would sometimes be admissible to perforate the head; and little compunction need be felt, as the infant is nearly if not always dead.

In a first labour, in which the pelvic cavity is so diminished that a mature ununited infant cannot be delivered, and also in those cases in which this mischief has taken place after the woman has naturally borne one or more children, the operation may be performed.

Embryotomy is justifiable in cases in which turning is quite impracticable. In these cases, the infant is nearly always dead.

In some cases of protracted labour, in which the pelvic organs or tissues have already sustained such great injury from pressure, and in which it would be extremely hazardous to the woman's life to deliver with the forceps, embryotomy may be practised. This event, however, will seldom or never happen in the hands of a judicious practitioner.

In some cases of hydrocephalic enlargement of the head, its size must be diminished by letting out the water by means of the perforator, or by a trocar. If this latter instrument can be successfully used, it is to be preferred.

Original Communications.

THE ENDOSCOPE AS AN AID TO THE DIAGNOSIS AND TREATMENT OF DISEASE.

By FRANCIS R. CRUISE, M.D. T.C.D., one of the Medical Officers to the Mater Misericordiae Hospital, and Lecturer on Medicine in the Carmichael School, Dublin.

[Read before the Medical Society of the King and Queen's College of Physicians in Ireland, March 15, 1865.]

MR. PRESIDENT AND GENTLEMEN,—I shall not occupy the time of the Society very long by the communication that I am about to make, although I feel convinced that its importance justifies me in trespassing upon your patience and attention.

I believe it will be granted by all, that one of the most important characteristics and improvements of modern medicine, consists in the direct exploration of organs, for the elucidation of their physiology and pathology.

This tendency to rest our knowledge upon physical rather than on rational signs, is one of by no means recent date; although, of latter days, it has become more obvious and better appreciated. Undoubtedly, within the last fifty years, it has made gigantic progress.

Percussion, methodised by Avenbrugger and popularised by Corvisart, seems but to have paved the way for Laennec's discovery of the immeasurable practical value of auscultation. Again, other portions of the body, lending themselves even more freely to examination than the thoracic organs, in due course have come to be objects of research with special observers, who, from time to time, have devised means and instruments for their more satisfactory investigation and study. Without delaying upon this point at the expense of the valuable time of the Society, I may quote, in illustration, the revival by Recamier of the long forgotten speculum uteri; also, the speculum auris, originated, I believe, by Newburg; the ophthalmoscope of Helmholtz; the laryngoscope of Czermak; and, though last certainly not least, the endoscope of Desormeaux; which latter instrument I have, on the present occasion, the honour of publicly exhibiting for the first time, I believe, in Ireland.

Agreeably to the old adage, that "Nought is new under the sun", as each of these valuable additions to our means of diagnosis has been brought under the notice of the profession, claimants have sprung up to dispute the honour and credit of invention.

I fear it would be very unprofitable, were I at the present time to discuss at length the precise merits of the competitors in each case; I shall, therefore, pass by that question; merely observing, in order to justify the quotation of the above-mentioned names, that I have endeavoured to associate with each method and instrument the name of that individual who has done most to demonstrate and extend its practical utility.

With respect to the endoscope in particular, I may observe that Desormeaux, in the introductory chapter of his recent valuable memoir, candidly acknowledges that the idea of an instrument capable of throwing light into deep cavities, such as the bladder and urinary passages, was not original with him.

He accords to M. Segalas the merit of originating the thought; and alludes to his unsuccessful attempt, as well as to the fruitless labours in the same direction of the late Mr. Avery of London and Dr. Hacken of Riga. He is in error in giving the palm of ori-

ginality to M. Segalas; for in 1806 Burrini of Frankfurt invented an instrument for the purpose; and others shortly afterwards followed up the matter, including the celebrated Dr. Fisher of Boston, U.S. Withal, it must be acknowledged that to M. Desormeaux alone is due the credit of patiently working at endoscopy, working for more than thirteen years, until he has at last produced a mass of facts so important and interesting that it is impossible for the profession any longer to ignore the subject.

A propos to the slight shewn towards the endoscope, a long and amusing history might be written of the opposition which has greeted every improvement in the science and art of medicine from its earliest days. Such a history would, I conceive, be out of place here. Frivolous objections avail nothing at the time when they are advanced, and only afford material for merriment and ridicule in the future. The practical commentary upon all such opposition lies in the contrast between medicine as we now see it, and medicine as our fathers knew it little better than half a century ago.

I shall not trespass on the valuable time of the Society by recounting a detailed history of my own labours at endoscopy. Suffice it to say, that it has been a dream with me since I became a student, and a pursuit after which I continually hankered. Years ago I tried to work with Desormeaux's endoscope; but, finding the light insufficient, gave it up in despair; and it is only of late that I resumed the study. Quite recently, a modification of the illuminating portion of the instrument occurred to me. I carried it out; and believe I have thereby succeeded in obtaining as much light as is needful for practical purposes. Since then I have worked assiduously, and have lost no opportunity of extending my experience of the endoscope. For my own part, I am quite satisfied that it is a most useful instrument; and I now venture to bring it publicly forward to receive the criticism and judgment of others.

The endoscope is an instrument devised and constructed for the purpose of throwing light into certain regions of the human body entirely out of the range of natural vision. That it is a most unquestionable success, I am satisfied; and I feel justified in stating, that I am convinced its field of practical utility is almost illimitable. I would venture to hope that, in the course of time, it may work as complete a revolution in our knowledge of many obscure diseases, as the stethoscope has wrought in the diagnosis of affections of the lungs and heart.

I hope, at no distant period, to bring before the profession a *résumé* of the work which it has already accomplished in certain branches of pathology; and to point out the principal new facts which it has brought to light, and the facilities it affords in the treatment of many ailments.

On the present occasion, I shall but briefly allude to its manifold capabilities.

The endoscope at its birth met with but little favour, and for many years was absolutely slighted and passed by. Desormeaux tells us how one of his teachers, unable to deny the reality of the instrument, merely asked him a question—"Of what use is it?" The answer to that query conveys its whole worth; namely, it enables us to see parts which, without its aid, are invisible.

Let us for a moment contrast the predicament of the physician called upon to treat a malady which it is possible for him to see, and one hidden from his view. For example, let us take a case of diseased eye, and a case of diseased urethra.

He will not content himself by calling the former an ophthalmia, without ascertaining what structure is engaged and wherefore. He will examine the lids,

the conjunctiva, the cornea, lens, and, if need be, will take his ophthalmoscope and investigate the vitreous humour and retina. It is needless to say how much information he may obtain from this simple inspection, both of the seat of the disease and of its nature, whether traumatic, catarrhal, arthritic, syphilitic, scrofulous, or others. His correct diagnosis lays the foundation for a truthful prognosis and rational treatment.

What, in contrast, is his position with respect to a case of blennorrhœa? In many, perhaps in most, instances, he can only guess out, by uncertain symptoms and unreliable antecedent history, whether the discharge arise from simple catarrh, from chronic inflammation, from relaxation of the mucous membrane, from syphilitic ulceration, from herpetic excoriation, from a granular condition of a segment of the canal, from disease of the prostate, and so on. In his uncertainty, his treatment must be empirical, and his prognosis unreliable; because he can neither tell the nature of the disease—whether communicable or not; nor can he foresee whether it will prove harmless in its results, or likely to lay the foundation of organic constriction.

However, the endoscope alters the case materially, and, as I think, for the better. By its aid, the urethra can be minutely examined, from its orifice to the neck of the bladder. Each single speck of disease can be ocularly demonstrated, and, if need be, subjected to precise local treatment.

I shall reserve for a future communication a detailed exposition of the symptoms of these several diseases of the urethra, as demonstrated by the endoscope; and shall now merely quote, for illustration's sake, a few cases recently seen by myself and others.

A few days ago, Dr. Fleming, of the Richmond Hospital, kindly invited me to examine for him a case of traumatic stricture now under his care. With the endoscope, I was able to exhibit the stricture with the utmost clearness, although it was situated four inches and a half from the glans. I was, moreover, able to point out the exact situation of the orifice, below and to the left hand side, and to introduce a probe into it. Dr. Fleming and Professor R. W. Smith were perfectly satisfied with the clearness of the demonstration.

I need not dilate upon the practical value of such an opportunity. Desormeaux mentions the case of an impassable stricture, in which Civiale, whose skill as a catheterist is undoubted, failed, after repeated efforts, to introduce an instrument, and finally called upon him to try what assistance the endoscope could give. By its aid the stricture was easily seen, and an instrument passed into the bladder.

An organic stricture, in a patient of my own in the Mater Misericordiæ Hospital, was, with equal facility, demonstrated, and, although previously quite impassable, I succeeded this morning in introducing a probe with the aid of the endoscope. Dr. Hayden, who is now present, did me the favour of examining this case, and will bear me out in what I state regarding it.

I do not wish to anticipate my intended communication upon the utility of the endoscope in various situations; but I cannot leave the subject of urethral stricture without alluding to its incalculable value in those cases in which urethrotomy is required.

With the endoscope the stricture may be divided in the sight of the operator, who can select, according to the circumstances of the case, the direction and extent of his incision. He is thus enabled to divide the callous parts alone, without trenching upon the healthy structures; and we shall see how important this is in a practical point of view, both as

regards the immediate and the ultimate consequences of the operation.

I may mention another out of many instances of disease of the urethra in which I lately obtained precious information from the endoscope.

A gentleman, aged about 24 years, of strumous and delicate habit, contracted blennorrhagia fifteen months ago. When partly cured of it, he caught a second infection some months later. The disease proved obstinate; and, despite a vast amount of treatment, he retained a chronic discharge with some scalding, and latterly was annoyed by slight dysuria and by a swelled and tender testicle. Recently, he placed himself under my charge. I carefully examined the urethra with the endoscope, from the neck of the bladder to the orifice. The condition of parts which I discovered was as follows.

The prostatic portion of the urethra was injected and slightly inflamed. The membranous portion was nearly quite healthy. The bulbous portion was *ulcerated and granular*; while the anterior four inches of the passage were perfectly healthy. In this case, I take it that the *real disease* is the ulcerated and granular condition of the bulbous portion of the urethra; that the congestion of the prostate is consecutive thereto, in consequence of the obstruction in passing urine; and that the orchitis is consequent upon the prostatic affection. Apart from the satisfaction of a precise diagnosis, the endoscope is doing good service by enabling me to apply concentrated caustic solutions to the granular ulceration; and, under this treatment, the patient is getting well. I do not know what other treatment could avail. A granular condition of the urethra will no more yield to mild injections than a similar state of the conjunctiva; and I could not use strong injections without damaging the anterior segment of the passage, which is at present sound. Of the importance and necessity of treatment in this case there can be only one opinion. This granular ulceration, according to the experience of Desormeaux, if left to itself, is sure to end in organic stricture; and the discharge from it is most undoubtedly contagious, as M. Thiry of Brussels has proved experimentally.

Time forbids my entering upon many other interesting points in the pathology of the urethra, which are cleared up by the endoscope; such as the connexion between its diseases and those of the testicle; the causes of the difficulty of healing urinary fistulæ; and so forth. In fact, I have delayed so long upon the subject, that it may, perhaps, be erroneously supposed that the sole use of the instrument is confined to those diseases. Far from it; there is no portion of the human body, into which a straight sound can be introduced, in which it will not be found of service. With it the interior of the bladder may be thoroughly investigated; tumours, ulcerations, and sacculi recognised; calculi examined and measured; and information gained respecting them as to form, number, position, whether encysted or loose, and so on. The rectum, beyond the reach of the finger and speculum, can be searched for ulcerations, constrictions, tumours, etc. The cavity of the uterus can be demonstrated; and it is needless for me to dilate upon the practical importance of this advantage. So also may the auditory meatus, the nasal fossæ, the pharynx, the larynx, and, I should even hope, the œsophagus. So recently as yesterday, I obtained most valuable information from an endoscopic examination relative to the precise attachment of a huge nasal polypus. Wounds, especially those suspected to contain foreign substances, may be searched with the endoscope; likewise abscesses; the cavities of ovarian cysts after paracentesis; etc. In a word, I may safely assert that it is utterly im-

possible, in the present state of our knowledge, to affix limits to the usefulness of the instrument.

[Dr. Cruise, having read the foregoing paper, proceeded to exhibit and explain the construction of the endoscope which he uses, and to point out the means by which he obtains a light possessing the requisite qualities of *intensity, steadiness, and facility in adjustment*. These details will form part of another communication. A discussion followed the exhibition of the instrument, in which many present bore testimony to its value.]

A CASE OF ASCITES.

ACCOMPANIED WITH OVARIAN DISEASE, IN WHICH
PARACENTESIS ABDOMINIS WAS PERFORMED
FIFTY-FIVE TIMES.

By HENRY HEMSTED, M.R.C.S., Whitechurch, Hants.

M. B., AGED 23, living at Hurstbourne, Hants, came under the care of my father, Mr. T. R. Hemsted, on April 10th, 1859. For the preceding six months, she had suffered from frequent attacks of pain in the abdomen, with vomiting and retching. On each occasion, leeches were applied with relief for a time. She had been a patient both in the Southampton and the Winchester Infirmaries.

Upon examination, the abdomen was considerably distended, with distinct signs of fluctuation. In the right iliac region, upon deep pressure, a tumour was discovered, hard, and of about the size of an orange. The distension continued to increase, and such discomfort was thereby produced, that on July 14th, 1859, paracentesis abdominis was performed, and five gallons of liquid drawn off. No unfavourable symptom followed. But in a short time, the abdomen began again to increase; and within five weeks, the operation was again performed, when an equal amount of liquid was withdrawn. During the succeeding eighteen months, the operation was performed sixteen times.

In the spring of 1861, the friends became anxious to have the opinion of some eminent London surgeon. She was recommended to University College Hospital, and became a patient under Mr. Erichsen, on April 17th, 1861. He gave the opinion that the liquid was situated in the peritoneal cavity; but that there was superadded a small tumour, in the pelvis. He did not recommend any operative procedure, other than the withdrawal of the liquid as it was required. She was tapped twice during her stay in the hospital, a week intervening between the operations. The ordinary amount (five gallons) was obtained the first time, but only three the second. On May 20th, 1861, she returned to Hurstbourne, and again became a patient of my father's. From this time, it was necessary to perform the tapping every four, three, or two weeks, up to January 29th, 1863, when the operation was performed for the fifty-fifth and last time. She became greatly depressed, never rallying, and died in February 1863.

At the *post mortem* examination, the peritoneal cavity contained more than a gallon of liquid, clear, without any shreds of lymph. The membrane itself was much thickened; in some places resembling moist wash-leather. The viscera were all firmly adherent to each other. On the under surface of the liver, there was a layer of coagulable lymph, which could be torn off in shreds. In the pelvis, there was a tumour, of about the size of a child's head, partly occupying the right lumbar region. This tumour was connected with the broad ligament of the uterus, and proved to be the right ovary enlarged. After removal, its weight was eleven pounds. It was afterwards examined by Professor Harley of Univer-

sity College, who stated that it was an ordinary ovarian tumour, made up of numerous cysts. The other organs of the body were all healthy.

I have been induced to record this case, from the time it continued under observation—forty-seven months—for the number of times the operation of paracentesis was performed—in all fifty-five times; and from the large amount of liquid withdrawn, at the lowest estimation, two hundred and seventy-five gallons.

The history of the case clearly pointed to some localised inflammation of the peritoneum, limited to the region of the right ovary, and having, as its cause, some irritative action of the organ. The ovarian tumour, in all likelihood, was never punctured; but at every time the trocar was introduced, the liquid was obtained from the cavity of the peritoneum.

Reviews and Notices.

HANDBOOK OF SKIN-DISEASES FOR STUDENTS AND PRACTITIONERS. By THOS. HILLIER, M.D. Lond., Member of the Royal College of Physicians; Physician to the Skin Department of University College Hospital, etc. Pp. 367. London: 1865.

HERE is another book on skin-diseases; and, like other writers on the subject, the author makes a classification of his own. This classification is a mixed one; partly founded on the natural affinities of the diseases, and partly on Willan's principle of elementary lesions. Dr. Hillier arranges all skin-diseases under four main divisions—Acute Specific Infectious Diseases; Parasitic Diseases; Syphilides; and Other Diseases. The last division includes the exanthems, vesicular, pustular, papular, squamous, hemorrhagic, and pigmentary diseases, diseases of the sebaceous glands, and of the nails and hairs, gangrenous inflammations, hypertrophies and degenerations, and heteromorphous exudations. Those who would study more closely the merits of this classification must consult the book itself. For ourselves, we most heartily wish that dermatologists would come to some agreement as to the best method of arrangement, and use it until something better, and allowed generally to be better, shall have been found. There is, however, one consolation: that, whatever be the classification, whatever the place in a system which a disease may assume, the variety of opinion as to this has comparatively little influence on the most important question at issue—that of its treatment. Skin-disease physicians treat skin-diseases—eczema, herpes, impetigo, tinea, or whatever they may be—according to the nature of the case and by their best judgment thereon.

It is, then, principally as a practical book that we have to regard this manual of Dr. Hillier's; and here we find much merit in it. Among the preliminary chapters, there are some very useful ones, concisely but clearly written, on definitions and other general matters. Thus, the fourth chapter contains a definition of the terms Exanthemata, Papules, Tubercles, Vesicles, etc. In the fifth chapter, *Ætiology* is discussed; and here the author shows how in some cases skin-diseases depend sometimes on affections of the general system, sometimes on diseases of individual internal organs; how skin-diseases

may arise from want of cleanliness, from irritation, occupation, or contagion; how their production may be influenced by age, hereditary transmission, diet, climate, etc. At the end of this chapter, are some remarks on the popular notion of vaccination being the cause of skin-diseases.

"No doubt" (says Dr. Hillier) "many children become eczematous very shortly after vaccination; but then it must be remembered that vaccination is usually performed at an age when eczema is very apt to occur without vaccination. In many families, nearly every child is liable to eczema during the whole period of primary dentition, whether it is vaccinated or not. The slight febrile disturbance attending dentition brings out eczema, and the slight disturbance of health caused by vaccination is also sometimes sufficient to determine the occurrence of an attack of eczema in children naturally predisposed to it." (P. 27.)

In like manner, Dr. Hillier has seen strophulus, impetigo, pemphigus, and pityriasis rubra, connected, or apparently so, with vaccination.

"There is nothing improbable in the notion that the introduction of virus like that of vaccinia into the blood of an unhealthy person may so unsettle the health as to lead to subsequent cutaneous eruptions; just as an attack of measles, an attack of variola, or even of varicella, may have this effect. The cases in which this occur are, however, so few as to form no argument against the general adoption of vaccination; but probably supply sufficient reasons for attending to the health of the subjects submitted to vaccination, as well as to be careful not to take vaccine virus from children of unhealthy constitutions. On this latter head the evidence is not very clear; but it would tend to show that the blood at any rate of a syphilitic child, if not the vaccine lymph from it, may lead to syphilis, although *a priori* one would be loath to believe in the possibility of such an occurrence. There is no evidence that scrofula or rickets can be inoculated; but it is better to err on the side of caution, and to avoid taking vaccine from children decidedly scrofulous or rickety." (Pp. 27-28.)

The sixth chapter is on Diagnosis and Therapeutics. Here Dr. Hillier describes the course which should be followed in examining a patient, especially in doubtful cases; and shows how it is often important to examine the whole body by daylight, to note the temperature at which the examination is made, to ascertain whether the patient have recently taken a cold or a warm bath, to note the condition of the skin, hairs, and nails, the age, sex, occupation, general health, of the patient, etc. This chapter contains also an outline of the principal therapeutic means employed in the treatment of skin-diseases.

The remainder of the book is occupied with a description of the various skin-diseases and their appropriate treatment. In his remarks on these, Dr. Hillier carries out the principle of attending to the constitutional as well as to the local conditions of the case.

Dr. Hillier, as physician to the skin department of a large general hospital, has had the duty devolved on him of instructing others in nature and treatment of cutaneous affections. For their guidance, he has written this work, using in its production both his own experience and the information which he has derived from the study of leading works on dermatology. He has thus produced a very useful

book, simple, practical, and well adapted, in our opinion, to give students and practitioners a good idea of the characters of skin-diseases and of the treatment which they require.

A MANUAL OF PRACTICAL THERAPEUTICS, considered chiefly with Reference to Articles of the Materia Medica. By EDWARD JOHN WARING, F.R.C.S., F.L.S., Surgeon in Her Majesty's Indian Army. Second Edition. Pp. 956. London: 1865.

THIS is the second edition of a very useful work which first appeared about eleven years ago; and it has undergone a thorough revision at the hands of the author.

After an introduction, Mr. WARING, in the first part, takes up the articles of the materia medica in alphabetical order; and, having given a brief note of the physical and other general properties of each, notices the medicinal properties and action, the official preparations, doses, etc. He then gives, under the head of "Therapeutic Uses", a statement of the conditions in which the employment of each medicine has been recommended by various writers. This part of the work must have cost the author a great deal of research through periodicals, etc.; and we can well understand how difficult he must have found the task when he was preparing the first edition in a remote station, rarely visited by ships, and where books were procurable only with much difficulty and delay. This edition has, we believe, been brought out under much more favourable conditions; and is very complete.

In the second part, the author treats of Medicinal Agents and Classes of Medicines, *e. g.*, Acids, Acupuncture, Affusion, Alkalies, etc. He gives also an Index of Diseases, for the purpose of directing attention to the paragraphs in which are mentioned the several remedies for each.

We can strongly recommend this work to the busy practitioner who has not time to search through numerous books and periodicals to find out what has been recommended in the treatment of any particular disease. Mr. Waring has gone through the laborious task of arranging for him all information of this kind, we believe, that was of any value when the book was written; and he has done it in such a way as to be at once available for use.

INDIAN SANITARY MOVEMENTS. The disclosures of Lord Herbert's Sanitary Commission made a reform in our Indian cantonments and hospitals imperative. Lieutenant-Colonel Crommelin prepared able reports on the subject, on which the government of India has issued orders. Miss Nightingale will be delighted with the orders issued by the government of India as to the structure and size of the barracks for both married and unmarried soldiers. Not more than from 44 to 66 men are to be massed under one roof; not more than from 16 to 20 single men are to sleep in the same room, and that must always, except in the hills, be on the upper floor; each man in the Plains will have 90 superficial feet of space and 1,408 cubic feet of air; all lavatories and other conveniences will be in detached buildings; the married quarters will be grouped in blocks according to troops and companies, and each couple will have one large room.

The Medical Council.

REPORT OF PROCEEDINGS, APRIL 1865.

THE Medical Council commenced its session on Tuesday last, April 4th, at the College of Physicians. There has been no change in its constitution since last year.

TUESDAY, APRIL 4TH.

G. BURROWS, M.D., President, in the Chair.

All the members were present, except Dr. Alexander Wood of Edinburgh and Dr. Allen Thomson of Glasgow.

THE PRESIDENT, in opening the proceedings, said that the peculiar nature of the business to be transacted rendered it necessary for the Council to meet somewhat earlier than usual. He regretted that the time fixed had not been altogether in accordance with the wishes of several members; but when he saw how the meeting was attended by men who occupied public positions and had other important duties to perform, it was plain that there would be a difficulty at any period in finding a time for meeting which should not be somewhat inconvenient. He referred to the difficulty in which, as President, he was placed, in having to fix the time of meeting; and had observed with pleasure that it was probable that some modification of the present plan would be suggested. He believed that the Irish Branch Council would propose a plan by which the several Branch Councils should be consulted as to the time of meeting; but, looking to the diversity of opinion which had been manifested in the present instance, he feared that this plan would not meet the difficulty. As for himself, he had allowed no personal considerations of his own to influence him as to the time of summoning the Council. The Council would have two main questions for discussion; viz., the amendments of the Medical Act, and the Report of the Select Committee on Medical Education. He was glad to see a notice of motion on the business paper for bringing forward the first of these subjects at once; and he hoped that the question of Medical Education would be found ripe for settlement. He concluded his remarks by expressing his confidence on the support he would receive from his colleagues in the Council.

Appointment of Committees. The *Business Committee* was appointed, to consist of Dr. Andrew Wood (chairman), Dr. Alderson, Dr. Embleton, Dr. Corrigan, and Mr. Rumsey. The *Finance Committee* was appointed, to consist of Dr. Sharpey, Mr. Arnott, Dr. Fleming, Dr. Aquilla Smith, and Dr. Quain.

The Medical Act. Dr. ANDREW WOOD moved—“That the consideration of the question of the Amendment of the Medical Acts shall take precedence of all other business.”

He urged on the Council the necessity of moving in regard to the amendments of the Medical Acts, if they would not be superseded by bodies outside. The medical profession were dissatisfied, and, if the Council did not act, would in all probability bring in a Medical Bill. He regretted that the Medical Council had not followed the recommendation of the Scottish Branch Council to meet at an earlier period—in January or February. If they had done this, they would have been able to have the Bill drafted and read a first time in Parliament before Easter. It would not be necessary, after the able exposition given last year by Dr. Corrigan, to recapitulate the

proceedings of the Medical Council in regard to the Medical Acts up to that time. He reminded the Council of the proceedings which took place last year. (See *BRITISH MEDICAL JOURNAL*, May 7th, 1864, p. 517; May 14th, pp. 535, 539, and 540.) The Council have before them the resolutions of the three Branch Councils; and it was now for them to decide on the basis of a Bill, to arrange the details, to send these to a solicitor to be drafted, and to remit the whole to the Executive Committee with very full powers.

Dr. CORRIGAN seconded the motion; but he did not expect any useful result from the deliberation of the Council this session. He proceeded to defend the Irish Branch Council from the charge of obstructiveness which, he said, had been brought against it. The Irish Council had indeed wished to postpone the time of meeting, not from any wish to obstruct business, but because Parliament would not be sitting during a considerable part of the present meeting of Council. He called attention to the fact that he had last year proposed, and Dr. Apjohn had seconded, that there should be an early meeting of the Council for the purpose of considering the Medical Act; and three other of the Irish members had voted with him. He considered that more obstruction had been offered to the amendment of the Medical Acts by the English Branch Council than by the Irish.

Mr. ARNOTT would not vote either for or against the motion. He feared that if the Council were to demand more compulsory powers, the question might be raised whether it was worthy of such powers; and also, whether its constitution was the best that could be adopted for the good of the public. He was not altogether satisfied with the constitution of the Council: it was too numerous.

Mr. HARGRAVE considered that the Council could not be charged with having done nothing; as it had effected a system of registration, had insisted on preliminary education, and had issued a Pharmacopoeia.

Dr. AQUILLA SMITH thought that the power of the Council had been tried; but that it had accomplished very little.

Dr. PAGET was of opinion that the time of meeting should have been earlier. The English Branch Council had not intended by their proceedings any discourtesy towards the Irish Council.

Dr. ANDREW WOOD, in reply, urged the necessity of an early application to Parliament for increased power to be given to the Council.

The motion was then put to the vote, and carried *nem. con.*

Dr. ANDREW WOOD moved, Mr. HARGRAVE seconded, and it was resolved—

“That the communications which have been received relative to the amendment of the Medical Acts, be referred to a Committee, with instructions to report upon them to the Council; the Committee to consist of Dr. Embleton (chairman), Dr. Paget, Dr. Fleming, and Dr. A. Smith.”

Dr. ANDREW WOOD moved, Dr. EMBLETON seconded, and it was agreed—

“That the resolutions of the Branch Councils on the subject of the amendments of the Medical Acts be now read.”

The resolutions were accordingly read, as follows.

RESOLUTIONS RELATIVE TO SECTION XX OF THE MEDICAL ACT.

Branch Council for England. Resolved—“1. That, consistently with the existing provisions of the Medical Act, the Medical Council may make known what they consider to be requisite as a sufficient course of education and examination, and may, if needful, represent cases of deficiency to the Privy Council, for correction; and that the Medical Council has, further,

the power of supervising examinations, with a view to their efficiency; that hitherto these provisions of the Act have not been proved by actual trial to have failed of their purpose, and that it would be impolitic to apply to the legislature for other powers until those already conferred shall have been practically shown to be insufficient.

"2. That whilst the Council have already a means of correcting proved deficiency, they would probably meet with serious difficulty in framing a body of positive regulations to be sanctioned by the Privy Council as universally and rigorously obligatory; that, on the one hand, a scheme of education, which should carry such general assent in the Council as to obtain the sanction of higher authority, might be so general in its provisions as to involve no material alteration of existing regulations, and, if so, would be superfluous and nugatory; that if, on the other hand, it were rendered more specific and rigorous, it would be liable unduly to trammel the free action of licensing bodies and schools, and stand in the way of variations of procedure which might be salutary and convenient. Lastly, that a particular scheme having been once fixed by the Privy Council, no modification or re-adjustment could be obtained without recourse to the same authority; and that, although a system of rules were framed by the Medical Council, cases of alleged contravention would still have to be brought before the Privy Council to be construed and decided."

Branch Council for Scotland. "To confer on the Medical Council definite powers to issue to the various licensing bodies regulations on the subjects of preliminary and professional education and examination.

"In order to carry out this object, the Branch Council recommend clauses to the following effect.

"That it shall be lawful for the General Medical Council, from time to time, to issue to the various licensing bodies such regulations respecting the preliminary and professional education and examination of persons desirous of obtaining any of the qualifications mentioned in Schedule (A) to the Medical Act, as may appear to the Council fitted to secure, on the part of such persons, the requisite knowledge and skill for the efficient practice of their profession.

"That all such regulations as shall have been passed by a majority of two-thirds of the General Council shall be obligatory on all Universities, Colleges, and other bodies enumerated in Schedule (A) to the Medical Act of 1858.

"That, in the event of any of the said bodies not conforming to such regulations, it shall be lawful for the General Council, if they see fit, to intimate to the said body that it has not conformed to such regulations; and to direct that, in the event of the said body not conforming within six months after such intimation, the qualification granted by such body, after the lapse of the said period of six months, shall not be registered.

"That it shall be lawful for any body, in regard to which such direction shall have been given, to appeal to the Privy Council, who shall have power, if they see cause, to disallow the direction of the Medical Council.

"That it shall be lawful for the General Council to restore any right to registration which may have been suspended by them, when they shall be satisfied that their regulations have been conformed to."

Branch Council for Ireland. Resolved—"That the following be approved of as the amendment of Sect. xx, the words 'preliminary and professional' being inserted before the word 'education' in line 3.

"SECT. XX. It shall be lawful for the General Council to lay down such regulations respecting the preliminary and professional education and examina-

tion of practitioners in medicine, surgery, and pharmacy, as may appear to them fitted to insure adequate knowledge and skill in the several departments of the profession; and the said General Council shall then submit said regulations to Her Majesty's Most Honourable Privy Council. And the said regulations, if sanctioned by the said Privy Council, shall then be obligatory upon all Universities, Colleges, and other bodies enumerated in Schedule (A) to this Act."

RESOLUTIONS RELATIVE TO SECTION XXXI OF THE MEDICAL ACT.

Branch Council for England. Resolved—"That, whereas the legal effect of this section is to require the great majority of persons about to enter the medical profession to possess qualifications in medicine and surgery from two different bodies, to obtain which, such persons are repeatedly re-examined in the same branches of knowledge, and thereby subjected to superfluous and irksome labours and to serious embarrassment in the progress of their studies, as well as to extra expense, it is highly expedient that every means should be taken by the General Council to promote the adoption by qualifying bodies of the provisions of Sect. XIX of the Medical Act."

Branch Council for Scotland. It was resolved: "That the Scottish Branch Council, having considered the propriety of amending Clause XXXI of the Medical Act, are of opinion that what is objectionable in it would be obviated were the combination and cooperation of the licensing bodies, as provided for by Clause XIX, encouraged or even made obligatory, so that facilities may be given to medical students for acquiring the complete or double qualification, without having to pass repeated examinations on the same subjects, which is at once irksome and unnecessary; and in order that the public may be best provided with general practitioners, who have been educated and tested in every branch of the profession, as well physic as surgery."

Branch Council for Ireland. Resolved: "That the following be approved of as the Amendment of Section XXXI; the words, 'notwithstanding anything to the contrary in any other Act or Acts,' being inserted after the word 'Act,' in line 1:

"SECTION XXXI. Every person registered under this Act, notwithstanding anything to the contrary in any other Act or Acts, shall be entitled, according to his qualification or qualifications, to practise medicine, or surgery, or pharmacy; or medicine, and surgery, and pharmacy, as the case may be, in any part of Her Majesty's dominions, and to demand and recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients: Provided always, that it shall be lawful for any College of Physicians to pass a bye-law to the effect that no one of their Fellows or Members shall be entitled to sue in manner aforesaid in any court of law, and thereupon such bye-law may be pleaded in bar to any action for the purposes aforesaid commenced by any Fellow or Member of such College."

RESOLUTIONS RELATIVE TO SECTION XL OF THE MEDICAL ACT.

Branch Council for England. Resolved: "That, in the opinion of this Branch Council, Section XL of the Medical Act should be amended as follows:

"Any person practising medicine or surgery, or being engaged in the treatment of diseases or injuries, for gain, not being registered under this Act, nor being able to give evidence of being qualified to be registered under this Act, who shall take or make

use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any professional title, name, or distinction commonly used by, or used to distinguish, duly educated or qualified practitioners in medicine or surgery, shall, upon a summary conviction, be liable to a penalty not exceeding £ for each offence."

Branch Council for Scotland. "To amend Clause xl, so as to render it more efficient than it has hitherto been, for enabling the public to distinguish between qualified and unqualified practitioners, and for preventing unqualified practitioners from assuming medical titles to which they have no right.

"In order to carry out this object, the Branch Council recommend a clause to the following effect:

"It shall not be lawful for any person, unless registered under this Act, to practise any branch of the profession, taking or using the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical Practitioner, or General Practitioner, or Surgeon-Apothecary, or Licentiate or Practitioner in Midwifery, or Professor of Medicine, or Professor of Surgery, or any other medical or surgical title; and every unregistered person so offending shall, upon summary conviction for such offence, forfeit or pay a sum not exceeding £20."

Branch Council for Ireland. Resolved: "That the following be approved as the Amendment of Section XL:

"SECT. XL. On and after the day of 186 , it shall not be lawful for any person, unless registered under this Act, to pretend to be, or to take or use the name or title of Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, or Surgeon, or Apothecary, or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other medical or surgical name or title; and any unregistered person so offending shall forfeit and pay a sum not exceeding £20, to be recovered in a summary way before the justices of the peace."

Dr. ANDREW WOOD moved:

"That the Council now proceed to consider the expediency of amending Clause xx of the Medical Act; and that the following resolution be adopted:

"That the amended Bill shall contain clauses conferring on the Medical Council definite powers to issue to the various licensing bodies regulations on the subject of preliminary and professional education and examination; and that, in order to carry out that object, clauses to the following effect be adopted, viz.:" (Dr. Wood here introduced the resolutions of the Branch Council for Scotland.)

He urged that the present plan, according to the Medical Act, of reporting contumacious bodies to the Privy Council, was difficult of operation, and involved an invidious exercise of power. The Irish Branch Council had proposed to amend this by providing that the regulations issued by the Medical Council should receive the sanction of the Privy Council before coming into operation; but with this plan there would be a difficulty in subsequently altering resolutions. The alteration proposed by the Scottish Branch Council would give the Medical Council the power of remonstrating and otherwise dealing with refractory corporate bodies; there, however, being the right of appeal to the Privy Council.

Mr. SYME seconded the resolution, observing that it had in the course of time become apparent that the compulsory powers given to the Council by the Medical Act were ineffectual. The Council had last year

been informed of numerous instances in which their recommendations had been departed from.

Mr. ARNOTT said that the College of Surgeons of England had carried out the recommendations of the Council in regard to preliminary education. He considered that moral suasion was more likely to effect good than was compulsion.

Mr. COOPER and Mr. HARGRAVE also made some remarks.

Dr. CORRIGAN proposed, as an amendment—

"That the whole Medical Act be taken into consideration, clause by clause, for approval or amendment; as the taking into consideration of only three clauses must lead to an imperfectly considered Bill, which would not command attention from the Legislature."

If a Bill were brought before Parliament, the first question asked would be, whether the Medical Council had considered and agreed on all the clauses. In order to be able to go before the Secretary of State with any weight, the Council ought to be able to say that they had examined the whole matter from beginning to end. He thought that the powers proposed to be given to the Council by Dr. Andrew Wood's resolution were very arbitrary; and he knew no other instance, at least in Ireland, in which a board had such arbitrary power given to it.

Dr. SHARPEY seconded the amendment. It would be important to have considered the bill throughout: it would not be necessary to discuss every clause, and those which required amendment would come under notice in their turn. He believed that there was an erroneous notion prevailing in the Scottish Branch Council as to the necessity of bringing about uniformity of practice in medical education and examination; but this, even if desirable, could not be effected in the present constitution of the Council. The power of the Council was not, he thought, intended to be exercised in a direct manner, but through the medium of the licensing bodies. It was not intended by the framers of the Act that the Council should fuse all medical education and examination into one mould, but that they should see that none of the licensing bodies fell in their requirements below what was a safe standard for the practice of medicine and surgery. It was only in general points, such as the subjects of study, the division of examination, preliminary examinations, and registration, that any attempt at assimilation could be successful. Beyond this, as, for instance, in regard to the order of study, and the question whether or not education should be conducted by lectures, any attempt to make absolute regulations must prove unsuccessful. He referred to the different institutions of the University of London and of the Scottish Universities, in illustration of the impossibility of issuing regulations which should be universally applicable. In these discussions, the power of visiting examinations had been lost sight of. He believed that this, if carried out, would have a very good effect. The objection of expense had been raised; but he thought that inspectors might be appointed, to be paid out of the monies raised under the Medical Act, and from any further source to be provided by Parliament.

Dr. CHRISTISON agreed that it was advisable to consider the whole Act; and would support Dr. Corrigan's amendment.

Dr. PAGET suggested that the clauses on which amendments were proposed should be discussed first, and the remainder of the Act examined afterwards.

Dr. STORRER said that the Council had never tried its powers in regard to the licensing bodies, and therefore it would be absurd to ask for greater power.

Dr. AQUILLA SMITH agreed with these remarks, and said that the disregard by many licensing bodies

of the recommendation of the Council afforded a good opportunity of testing the powers of the latter body.

Dr. QUAIN supported the suggestion of considering the more important clauses of the Act in the first place.

The amendment was then put to the vote, when there appeared, For, 7; Against, 11. It was consequently lost.

The original motion being put, 3 voted for it, and 14 against it; so that it also was lost.

WEDNESDAY, APRIL 5TH.

G. BURROWS, M.D., President, in the Chair.

The same members were present as on Tuesday, with the addition of Dr. Allen Thomson.

The minutes of the last meeting were read and confirmed.

The Medical Acts. Clause xx. Dr. ANDREW WOOD moved the following resolution—

"That the following be adopted as an amendment of Clause xx of the Medical Act:—'It shall be lawful for the General Council to lay down such regulations respecting the education and examination of practitioners in medicine and surgery as may appear to them fitted to ensure adequate knowledge and skill in the practice of their profession. And the said General Council shall submit said regulations to her Majesty's most honourable Privy Council. And the said regulations, if sanctioned by the said Privy Council, shall then be obligatory upon all universities, colleges, and other bodies enumerated in the Act. And it shall be lawful for the Privy Council, upon its being represented to them that any university, college, or other body enumerated in the Act does not comply with such regulations, to declare that any qualification granted by such university, college, or body shall not confer any right to be registered under the Act. Provided always, that it shall be lawful for her Majesty, with the advice of her Privy Council, when it is made to appear to her, upon further representation from the General Council or otherwise, that such college or body has made effectual provision, to the satisfaction of such General Council, for the improvement of its course of study or examinations, or the mode of conducting its examinations, to revoke any such order.'"

He observed that the votes of the previous day did not foreclose the further discussion of the amendments of Clause xx; and he considered it right that there should be an opportunity of deciding on a resolution based on the recommendation of the Irish Branch Council. This resolution provided for the Medical Council less power than the Scottish resolutions; but it would relieve them from a difficulty which had impeded them for years. It was perhaps better not to increase the power of the Council; but the existing power should be made more definite. Hitherto the Council had been accustomed to represent certain proceedings as "desirable," and to "recommend" them; and the result had been that the licensing bodies had not felt themselves bound to attend to the recommendations. This was wrong; for if three or four boards followed the recommendations of the Council and the others did not, those which obeyed were placed at a disadvantage. He would here observe, that the College of Surgeons of Edinburgh, having protested against the proceedings of the Council, had decided on obeying in future the recommendations as to preliminary education. It would be better if, after the resolutions were agreed to by the Council, they were strengthened by the authority of the Privy Council before being sent to the licensing bodies. There should be no fear in granting this power. The time had come when the

Council ought no longer to be met with the charge of not having power to enforce its regulations.

Dr. LEET seconded the motion.

Mr. SYME moved as an amendment—

"That Clause xx shall stand as at present; and that if any of the bodies mentioned in Schedule (A) should decline or neglect to comply with the recommendations of the Council, in regard to education—whether preliminary or professional—the Council shall, if they see fit, express their disapprobation."

He was in favour of the exercise of moral suasion rather than compulsion.

Mr. HARGRAVE seconded the amendment.

Dr. CORRIGAN supported the original motion.

The amendment was put to the vote, when there appeared, for, 10; against, 11. It was consequently lost.

Dr. EMBLETON proposed, and Mr. RUMSEY seconded, as a further amendment—

"That Section xx of the Medical Act of 1858 stand as at present."

Dr. FLEMING believed that it was the intention of the legislature in passing the Medical Act that some power should be given to the Council; and he considered that the Council ought to endeavour to obtain more power than it at present possessed. If the resolutions of the Medical Council were sent to the Privy Council for approval they would be referred to some member of the medical profession, who would thus be placed in a position superior to the Council.

Dr. CORRIGAN said that the power of the Medical Council had never been tried, and he believed it never would be. There were plenty opportunities of trying it at once—even within the next two days.

After some remarks from Mr. ARNOTT and Mr. HARGRAVE, the votes were taken for Dr. Embleton's amendment with the following result: For, 11; against, 9.

The amendment was now about to be put as a substantive motion, when

Dr. PARKES moved as a third amendment—

"That Section xx be amended as follows:

"'That it shall be lawful for the General Medical Council, from time to time, to issue to the various licensing bodies such regulations respecting the preliminary and professional education and examination of persons desirous of obtaining any of the qualifications mentioned in Schedule (A) to the Medical Act, as may appear to the Council fitted to secure, on the part of such persons, the requisite knowledge and skill for the efficient practice of their profession.

"'That all such regulations as shall have been passed by a majority of three-fourths of the General Council shall be obligatory on all Universities, Colleges, and other bodies enumerated in Schedule (A) to the Medical Act of 1858.

"'That, in the event of any of the said bodies not conforming to such regulations, it shall be lawful for the General Council, if they see fit, to intimate to the said body that it has not conformed to such regulations; and that, in the event of the said body not conforming within six months after such intimation, a representation be made to the Privy Council, to authorise the suspension of the registration of the degrees or licences of such body.

"'That it shall be lawful for any body, to which such an intimation shall have been given, to appeal to the Privy Council, who shall have power, if they see cause, to disallow the direction of the Medical Council.

"'That it shall be lawful for the General Council to recommend the restoration of a right to registration which may have been suspended by the Privy Council, when they shall be satisfied that their regulations have been conformed to.'"

It was wrong to prejudge the possibility of obtaining an amended Act this session; the Council should frame as good a bill as they could and endeavour to get it passed. He did not agree with the depreciatory opinions that have been expressed as to the utility of the Council.

Dr. FLEMING seconded the amendment.

After some remarks from Mr. SYME, Dr. CORRIGAN, and Dr. ANDREW WOOD, the amendment was put to the vote and lost; 5 voting for and 12 against it.

Dr. EMBLETON's amendment was now put as a substantive motion and carried by a majority of 12 to 8.

Clause XXXI. Dr. QUAIN moved—

"That the Clause remain as at present."

Dr. ALDERSON seconded the motion.

Dr. EMBLETON moved as an amendment, and Dr. PAGET seconded—

"That the consideration of Clause XXXI be deferred until the Council is made acquainted with the provisions of the Pharmacy Bills at present before Parliament."

The amendment was carried; 11 voting for and 7 against it. It was also carried as a substantive motion.

Clause XL. The resolutions passed by the three Branch Councils in reference to this Clause, were read.

Dr. QUAIN said that hitherto the Clause had failed in carrying out the object expressed in the preamble of the Act—that of enabling the public to distinguish between qualified and unqualified practitioners of medicine. He considered that the amendment proposed by the English Branch Council was sufficient. There was one point in which it diverged from those of the Branch Councils of Scotland and Ireland; these required that every one in practice should be registered. But he feared that it would be impossible to bring about compulsory registration. He did not think that the universities would consent that their graduates should be prevented from using the title of M.D. unless registered. Again, the resolutions of the other Branch Councils would prevent doctors of divinity, or of laws, from using the title of doctor. He proposed the adoption of the recommendations of the Branch Council for England, omitting the words "for gain" (in the third line of the paragraph).

Dr. PAGET seconded the motion. The resolutions of the Branch Council for Ireland would act harshly on persons holding degrees but not intending to practise. He referred to a distinguished member of the University of Dublin who was in this position; and also to the Professor of Anatomy at Cambridge, who, although he had no intention of practising, had and used his university title.

Dr. ANDREW WOOD said that the cause of the failure of Clause XL had been, that the penalty was laid, not on practising or taking a title, but on wilfully and falsely pretending to be registered. It was necessary to amend the Clause so as to render very little evidence necessary for conviction. He would propose the adoption of the Clause recommended by the Branch Council for Scotland; and observed that the rights of those who had titles but did not intend to practise were saved by it. If it were necessary he would be content to sacrifice the few for the good of the many; but by the Scottish amendment no sacrifice was required. As to the suppression of quackery, this would be impossible; before it could be done, it would be necessary first to put down all who would be quacked. But it was altogether a different thing, whether persons should be allowed to impose on the public by the assumption of titles which they did not possess. That there were good reasons for endeavouring to suppress this, the records of the past year alone gave ample proof. The object of the Council

was to benefit the public, not themselves; but so long as the *Register* was incorrect, the legislation was against the public. Dr. WOOD remarked that he was glad to see that the chemists and druggists were endeavouring to organise a system of registration; but he found that in their analogue of Clause XL they were falling into the error from which the Medical Council was endeavouring to escape. The schoolmasters in Scotland were also endeavouring to obtain registration.

Some conversation having taken place, Dr. Andrew Wood said that he would not propose the resolutions of the Branch Council for Scotland, but those of the Branch Council for England with some alterations. He therefore proposed as an amendment:

"Any person practising medicine or surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or any professional title, name, or designation commonly used by, or used to distinguish, duly qualified practitioners in medicine or surgery, shall, upon a summary conviction, be liable to a penalty not exceeding £20 for each offence."

Dr. CHRISTISON seconded the amendment. He could not understand why qualified persons should not register.

Dr. ACLAND remarked, that the compelling of persons to be on the *Register* if in practice would give rise to complaints of being obliged to pay a fee in addition to that of their licences.

Dr. SHARPEY would support the amendment, because, if it were admitted that persons might practise medicine without being registered, the *Register* would represent only a fraction of the medical profession of the country.

Dr. QUAIN said that no one was more in favour of compulsory registration than himself; but he felt that it would not be practicable to obtain it from Parliament.

The amendment was then put to the vote; when there appeared—for, 14; against, 4.

It was then put as a substantive motion; when

Dr. CORRIGAN moved, as a further amendment, the adoption of the recommendations of the Irish Branch Council, omitting the word "Doctor" after "Bachelor of Medicine". There was apparently very little difference between this resolution and that of the Scottish Branch Council; but the Irish Council provided that conviction should depend on the assumption of a title recognised by law, whereas the Scottish Council required also proof that the person accused was engaged in practice. As to the hardship alleged to be inflicted on those who would be forced to register though not practising, the number of such persons would be but small; and it must be remembered that the Council had to provide legislation for the many, and not for the few. He thought that the few holders of degrees, not in practice, would willingly enter their names on the *Register*, if they knew that their doing so would be for the public good.

Dr. STOKES seconded the amendment.

Dr. PAGET could not agree with the amendment. The Medical Act was not passed for the purpose of acting penal against persons who do not practise nor intend to practise.

After some observations from Dr. Apjohn, Dr. A. Thomson, Dr. Quain, Dr. Christison, and Dr. Andrew Wood, the amendment was lost by 15 against 3.

Dr. ANDREW WOOD's amendment was now put as a substantive motion, and carried *nem. con.*

The Army and Navy Medical Departments. Dr. PAGET moved, and Dr. APJOHN seconded—

"That the communications from the Directors-General of the Army and Navy Medical Departments be printed, for the use of Members of the Council."

Dr. STORRER moved as an amendment, and Dr. ACLAND seconded—

"That the communications from the Medical Departments of the Army and Navy be read."

The amendment was carried; and, on being put as a substantive motion, was again carried.

On Thursday, certain reports from the Directors-General of the Army and Navy Medical Departments as to the candidates who had presented themselves during 1864 were read and ordered to be printed.

The same course was also followed in regard to some communications made to the Council on the amendments of the Medical Acts.

The Council then resolved itself into a Committee on education; and, after a long discussion, agreed on a scheme for the visitation of examinations.

British Medical Journal.

SATURDAY, APRIL 8TH, 1865.

MEDICAL EVIDENCE.

A CASE reported in the *Times* of the 1st inst. contains a striking illustration of the remarks lately made by us touching medical evidence in cases of injury from railway accidents. Nothing seems to have astonished judge, jury, and audience more in this case than what the reporter calls "one of the most extraordinary conflicts of medical testimony ever witnessed in a court of justice." What the Chief Baron thought of the medical evidence may be gathered from what he said of it in his summing up of the case.

"As to the medical evidence, it certainly was as opposed as that of valuers in railway compensation cases. One set of witnesses said that there was 'lesion' or organic injury; the other, that there was not. On one side, they stated that there was paralysis caused by the organic injury; on the other side, that there was a mere derangement of the nervous system, by reason of the concussion and the consequent shock."

Our readers, no doubt, well know what is meant by the conflicting evidence of valuers in railway compensation cases; and it is to such a level that medical evidence was brought in this case, in the opinion of the Chief Baron! In railway compensation cases of the kind referred to by the Chief Baron, the most prominent item is what is called the "hard swearing" of the valuers!

In the case referred to, the injured man, it was admitted, had received injury; and

"The question was as to the nature and extent of the injury, and whether it had caused a 'lesion' or organic injury to the brain. On the part of the company, this was disputed. There could be no doubt that symptoms resembling paralysis of the leg and arm on one side to some extent had supervened; but

what was disputed was, whether this was paralysis which arose from an actual 'lesion' of the brain or spinal cord, or was the mere effect of a shock to the nervous system, which might in course of time be cured and removed. The accident, it is to be observed, was in December; and it was beyond all doubt that he was still in a bad state, though it was disputed whether he was better or worse. Mr. Quain, the eminent surgeon, gave strong evidence as to the condition of the plaintiff, and declared that he believed it would have been dangerous to bring him into court. Galvanism had, he stated, been applied as a test so recently as Monday—using the galvanic current on the two limbs said to be paralysed; and the result was that, as a matter of fact—not of mere opinion—the right arm and right leg were paralysed. He declared that, in his opinion, the plaintiff was suffering from disease of the brain and nervous system. Dr. Walsh, with Mr. Richardson, Dr. R. Reynolds, and Mr. Hulke, were called to confirm the case on the part of the plaintiff. The accident having occurred in December, he had been, it was stated, getting worse ever since, and was now reduced almost to utter imbecility. Mr. Adams, Mr. Skey, Mr. Solly, Dr. Headland, Dr. Ratcliffe, and Mr. Critchett, were called on the part of the company. The effect of their evidence was, that there was no actual 'lesion' or organic injury to the brain, and that the symptoms of paralysis were the mere results of the shock to the nervous system. Indeed, one of them said he thought that they had been a great deal aggravated by the inquiries and examinations made by the numerous medical men (some ten or twelve) who had examined the plaintiff on the one side or the other. The strength of the evidence of the medical men on the part of the company was, in a word, that if there had been actual 'lesion' or organic injury, there would have been other symptoms not observable in this case; and that those which were observed were equivocal, and equally referable to a paralysis arising from disease or from shock to the nervous system; and, on the other hand, the value of the galvanic test was not admitted, and by some was disputed or denied. They denied, in short, altogether paralysis either of the brain or of the spine, and only admitted the effects of a severe shock to the nervous system; and the practical result of their evidence was, that in the course of a year, with entire cessation from labour, he would recover."

The jury eventually, notwithstanding the efforts made by the railway medical witnesses, gave the plaintiff £5,550 damages. But who shall assess the damage and injury sustained, through this trial, by medical evidence? This much every one of us must see, that, under such a process as this, medical evidence in courts of law becomes a mere byword—a *ludibrium* both before the public and justice. One of two things the public will argue, and reasonably argue. The public will say: "Either you medical gentlemen are incapable of coming to a definite opinion on a matter of fact—on a case of injury lying before you; you can come to no agreement between yourselves; you differ *toto celo*, six on one side and six on the other, in the matter; and, therefore, medical evidence in such a case is worth nothing: or we can only regard your evidence as of the same worth and character as that of the railway compensation valuers; and must conclude that doctors are at the service of a railway company to give

evidence, *pro* or *con*, just as surveyors and architects are. And of course, so concluding, we shall know in future what sort of credence is to be given to what you call your scientific evidence!"

Such, we take it, is the low estate into which medical evidence naturally and very properly falls by exhibitions of the kind here referred to.

THE Medical Council has passed a resolution to amend Clause XL of the Medical Act, which is, in our opinion, certain to prevent their proposed new Medical Bill passing through Parliament. Such a resolution really seems the condemnation of the Council as men of progress and business. It will be seen that the Council are about to call upon Parliament to give them powers summarily to prosecute and subject to fine, not only quacks and pretenders who call themselves doctors, surgeons, etc., but every qualified doctor of medicine, physician, surgeon, apothecary, etc., in practice, who shall assume any of those titles, unless he be registered. No doctor, or surgeon, or apothecary, the Council say, shall practise their art in this country—notwithstanding their legal right to practise as such—unless they pay us down hard cash, and have their names down on our *Register*. The Council seem to have completely forgotten that such a proposition is equivalent to a positive repealing of the Act of Henry VIII to the Royal College of Physicians, and of the Apothecaries' Act, and of other Acts of Parliament. This proposed clause is, in fact, actually a calling upon the Royal College of Physicians, Apothecaries' Hall, etc., to give up the right of granting powers to their Licentiates, etc., to practise medicine. Surely this is legislation run wild with a vengeance. Or have the Council forgotten all this, and been desirous only by such a proposed clause to throw a sop to the profession; and thinking that the proposition will expiate their little doings and much talkings in the eyes of the profession at large? We believe our medical brethren are too much alive to the facts of the case to be blinded by any such impossible a bait; and we sincerely trust they will themselves strenuously oppose it. The attempt to carry into Parliament such a clause is of itself sufficient to be fatal to their new Bill. Do the Council really believe that the Royal College of Physicians (within whose walls the resolution was passed) would allow their ancient legal rights to be thus summarily disposed of? that they would allow the privileges to practise granted by them to their Fellows, Members, and Licentiates, to be abrogated at the pleasure of the Medical Council? And what will every enemy of the Council say of it but this—the Council seems to care, above all, for one thing; viz., how to secure the funds necessary for carrying on their meetings.

MR. SOLLY complains, and most fairly, that his compulsory retirement from St. Thomas's Hospital in May next would be a hardship and an injustice. We fully agree with the propriety of limiting the time of service and the age of retirement of hospital medical officers, and have on many occasions strongly advocated the modern practice in this respect. But no laws or regulations of the kind can be justly made retrospective. The existing holders of office have a fair claim to hold office on the terms on which they entered upon the performance of its duties. Mr. Solly undertook his surgeoncy at St. Thomas's Hospital, under the terms of a tacit agreement with the Governors that he should hold office as his predecessors had done, and as the office was then held. Besides this, there is no pretence in the way of incompetency for Mr. Solly's retirement. We are sure, therefore, that the voice of the profession will go with us in this, that Mr. Solly ought, in all fairness, to be allowed to continue office up to the completion of his twenty years of surgeoncy.

POTTER, the murderer, to whose case we lately made special allusion, has been respited, and sent to Broadmoor Lunatic Asylum. After his condemnation, he was visited by Lunacy Commissioners; and, in consequence of their report, this decision was arrived at.

THE Report of the Committee appointed some months ago by the Royal College of Physicians, to inquire into the condition of the Army and Navy Medical Services, will be brought before the College on the 10th inst. The Committee have, we understand, thoroughly investigated the subject and completely satisfied themselves of the injustice inflicted on their brethren in the army and navy; and if we are rightly informed, the Committee will ask the College to take up the cause of the army and navy surgeons, in order to have their griefs sifted by Parliamentary inquiry; and they will also ask the College to request all the other medical corporations in the country to assist in the endeavour. We may add, as we do with much pleasure, that we have good reason to know, that if the Royal College of Physicians should decide on making application to Parliament, its application will receive the highest support both in Scotland and in Ireland. Our brethren in the army and navy, in the meantime, should be prepared to give their own strenuous support to the College, in the case of its making application to Parliament.

THE epidemic which is now raging in St. Petersburg and other parts of Russia, is evidently neither plague, nor any new disease, but the plain, old-fashioned, famine-fever, typhus, with its companion, relapsing-fever.

Our readers will have observed that in the recent K.C.B. honours (if so they can be called) recently distributed to the heads of the Army Medical Department, our naval brethren have been completely forgotten. We may remark, as a *solatium* to those who may consider themselves as thus overlooked in this matter, that the distribution of these honours has given no satisfaction to the combatant officers. The *Army and Navy Gazette* indicates that merit and service have had very little to do with the selections of combatants made for receiving such very dubious honours, whatever it may have had to do with the non-combatant selection.

IN *L'Imparziale* is an interesting account of the Vienna School of Medicine, addressed to the editor by Professor Sigmund of Vienna.

"For more than a quarter of a century pathological anatomy has been especially studied here. We have specialties, oculistic, obstetrical, and syphilitic, children's diseases, dermatology, etc. The medical men of the modern school are all made of new stuff. In our great hospitals—and too great they sadly are—every ward is, as it were, opened for special instruction; and every day we see increased the number not only of our own but of foreign students, who come to take advantage of the immense mass of scientific materials placed at their disposal. The dissecting-rooms, the two museums of anatomy, the new clinical and pathological laboratory, and the microscopical rooms, are always crowded, thanks to the liberal institution, which grants a ready admission to them; thanks, also, to the new system of electing professors without regard to their country or their religion. You may find in the Faculty of Vienna, by the side of Catholics, Protestants, Jews, and even Greeks! Annual and half-yearly examinations have been done away with. We have now only the examination for the doctorate. The thesis has also been abolished.

"In a few days will be opened a new hospital containing 800 beds. Vienna will then possess more than 4000 beds for the sick; viz., in the General Hospital, 2000 beds; in the suburb *Wieden*, 850; in the new Rudolph's Hospital, 800; in the Infants' Hospital, 100; in the Brothers of Charity Hospital, 350. To these may be added—the Hospital of the Sisters of Charity, with 200 beds; the Children's Small Hospital, 50; the Merchants' Hospital, 40; and the Jews' Hospital, with 60 beds—making altogether 4430 beds. Besides these, we have Military Hospitals containing 1500 beds; a Hospital for the Parturient with 250; a Foundling Hospital with 200; and Lunatic Hospital with 500. You may imagine, therefore, the immense pathological riches accumulated here. We shall, moreover, soon require another large hospital to meet the wants of the growth of the city.

"March 12th will be the five hundredth anniversary of the foundation of the University, and we shall then have a grand festival. It is not, however, yet decided whether the festival will be held on that day, or later, in August or October.

"Pathology occupies now a veritable palace by the side of the hospital; and with it are united magnificent rooms for pathological chemistry and legal medicine. One of our richest treasures is the Museum—by far the finest I have seen in any school. Here, also, you will find close at hand, a splendid collection of *matéria medica*, and a new institution, the Physiological Laboratory. And all these esta-

blishments flourish, notwithstanding the law passed fifteen years ago, which obliges the student to pay for his courses, etc. The payment of an *honorarium* increases the zeal of the student; and, under all circumstances, renders the condition of the medical man more honourable.

"Syphilis increases with us, as in all other large cities. Notwithstanding the separation of prostitutes, properly so called, I had under my charge in the year 1864 more than 2000 syphilitic patients, and my 275 beds are always full. I have concluded my fifty-fifth course; and you may, therefore, believe that I must soon give up this work, and leave it to younger and more vigorous shoulders."

"A BRIEF Sketch of the Past and Present Condition of the Bengal Medical Service, by a Surgeon of the Bengal Army," gives a very full historical, and, we believe, impartial account, of the subject with which it is concerned. The writer's opinion is, that Sir Charles Wood has not done justice to the Indian army medical officers. If strict justice be done, he says,

"We are entitled to expect the revocation of that clause in the Indian Warrant which confers upon assistant-surgeons *brevet* instead of *substantive* promotion for distinguished service; to expect that the scale of invaliding pensions granted to the British Army Medical Department by the Warrant of 1858 should be extended to our service; to look forward to receiving pensions on retirement more strictly in accordance with our army rank; and to claim for surgeons and surgeons-major in charge of regiments a staff allowance, in addition to the pay of their rank, more nearly proportioned to the responsibilities of their position than that which has been accorded to them by Sir Charles Wood's recent order. In addition, I believe we have a right to look for a speedy increase to the emoluments of civil and non-regimental charges based upon the increased pay granted to regimental officers; and also to hope for a speedy declaration on the part of Government of the exact meaning of their guarantee for maintaining the Service Funds, which are all of them rapidly verging towards insolvency, as a necessary result of the diminished number of subscribers consequent on the abolition of compulsory subscription from the period of the transfer of India to the Crown. This declaration has now been withheld, in spite of constant protest, for nearly six years; and the state of uncertainty which is the inevitable result has become almost unbearable."

THE plan of the future Hôtel-Dieu of Paris has been decided. The buildings will occupy the Quai Napoléon, the Rue St. Christophe, Rue de la Cité, and Rue d'Arcole. The buildings will extinguish some eight or nine small streets behind those above mentioned.

L'Union Médicale complains that, at a recent discussion at the Royal Medical and Chirurgical Society, on the Inhalation of Atomised Fluids,

"The name of the ingenious French inventor was not once mentioned. Every experimenter who has succeeded, who has either confirmed or disproved the fact of the penetration into the lungs of the pulverised liquid, was referred to. The discoverer's name alone was omitted; no doubt, on account of its being so well known!"

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
WEST SOMERSET. [Quarterly.]	Clarke's Castle Hotel, Taunton.	Wednesday, April 12, 7 P.M.
BATH AND BRISTOL. [Ordinary.]	Victoria Rooms, Clifton.	Thursday, April 13, 7 P.M.

WEST SOMERSET BRANCH.

A QUARTERLY Meeting of this Branch will be held at Clarke's Castle Hotel, Taunton, on Wednesday, April 12th, at 7 P.M.

Notice of papers or cases to be communicated should be sent to the Honorary Secretary previous to the meeting.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, March 11th, 1865.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETING.

THE third meeting for the eighth session, 1864-65, was held at the Infirmary, Gravesend, on March 31; C. J. PRINCHING, Esq., in the Chair. Seventeen members and visitors were present.

Communications. The following communications were read:—

I. Ophthalmic Cases. By M. A. Adams, Esq.
1. Diphtheritic Conjunctivitis. 2 and 3. Successful Extraction of Cataract in Diabetes. 4. Anophthalmos. (The patients were exhibited at the meeting, with the exception of one suffering from diabetes.)

II. Case of Embryotomy. By J. V. Bell, M.D.

III. Some interesting cases, inmates of the Infirmary, were brought before the meeting. 1. Railway injury in a young man; lower end of tibia removed; result satisfactory: viz., foot straight, with some degree of flexion and extension preserved. 2. Bullet lodged in lower jaw of a young man; sinus and some thickening, but no certain indication of the situation of the ball.

Next Meeting. Flaxman Spurrell, Esq., was elected chairman of the meeting to be held at Dartford in April.

Dinner. The members and visitors adjourned to dinner at the Yacht Club House.

HYDROPHOBIA. In connection with the bill for lessening the mischief occasioned to flocks in Ireland by vagrant dogs, Professor Gamgee publishes some interesting remarks on the spread of the hydrophobia and other evils from the number of dogs roaming about at will. He says: "It is impossible to estimate the serious amount of loss of life and property incurred by the people in Ireland from the dog nuisance. Swarms of parasites infest the bodies of cattle, sheep, and pigs, which they derive from dogs. Many animals are doubtlessly worried, and a very considerable number of men and animals are annually bitten and inoculated with the rabid virus." Hydrophobia in man is increasing in Ireland. For the ten years ending 1841 31 cases of death from this cause are reported. In 1851 the number had risen to 57, and in 1861 to 61. This is very different from what we find in England, where the deaths from hydrophobia have gone down year by year from 25 in 1851 to 3 in 1860. In Scotland, even allowing for the smaller population, the number is still smaller.

Special Correspondence.

DUBLIN.

[FROM OUR OWN CORRESPONDENT.]

Two cases of great interest have lately occurred here, which, I think, it will be worth your while to record. Therefore I send you brief notes of them.

The first is that of a Fracture of the Spine, in which the operation of Trephining was performed. The patient was a man named Joseph Collins, aged 38 years, who entered Jervis Street Hospital December 28th, 1864, suffering from an injury of the spine. Dr. Robert McDonnell, who saw him immediately after his admission, and under whose care he remained, at once diagnosed a fracture of the spine corresponding to the last dorsal or first lumbar vertebra. The symptoms were those of pressure on the spinal cord.

At a consultation held the same day, Dr. McDonnell advocated the immediate performance of trephining. His colleagues, however, not taking his view of the case, the proceeding was negatived.

The idea of trephining was then given up until January 30th, 1865, when Dr. Brown-Séquard, happening to be in Dublin, saw him with Dr. McDonnell. He supported his view, and advocated the operation as a *dernier ressort*. Accordingly, it was performed February 3rd, 1865.

Previously to the operation, sensation existed normally in the thigh and calf of each leg. In the feet, sensibility was much impaired, the sole being quite anæsthetic. Paralysis of motion was almost complete in both lower limbs; no reflex movements could be excited. The bladder and rectum were absolutely paralysed; the urine was alkaline. The penis and scrotum were swelled, and the prepuce ulcerated. Bed-sores existed over the sacrum; and the left foot and leg were œdematous.

After the operation, sensation became normal every where. There was a marked increase of motor power in the muscles of the thigh; the patient, however, did not regain the power of moving his toes. After some days, the reflex phenomena as regards movements of the muscles of the thigh reappeared. The most remarkable improvement, however, was in the penis and scrotum, etc. The ulcerations improved; the swelling diminished; and the œdema of the left leg disappeared.

A fortnight after the operation, the bladder had regained considerable power, and the urine could be expelled with some force. However, the patient sank on the seventeenth day after the operation, when it was found that inflammation had extended from the bladder to the kidneys, purulent depositions having been found in one of those organs.

On *post mortem* examination, a displacement was found to have taken place between the last dorsal and first lumbar vertebrae, with fracture of a portion of the body of the latter. The theca vertebralis was uninjured; the cord compressed, but not lacerated.

The operation consisted in the removal of the posterior arch of the first lumbar vertebra; and there is little doubt, had it been performed at an earlier period, there would have been a fair chance of interrupting the chain of sequences which led to a fatal result in this case.

The above is a mere sketch, as the whole details will soon be published in full by Dr. McDonnell.

The second case is one of no less importance than that just described, being the cure of an aneurism implicating the femoral and iliac arteries by compression applied to the common iliac and femoral vessels. The case occurred in the practice of Dr. Mapother of St. Vincent's Hospital, and presented extraordinary difficulties in its management. Among others, I may mention the fact of the treatment being carried out while the patient was under chloroform, and the combination of distal and proximal compression, so as to prevent complete emptying of the sac. This device is the suggestion of Mr. O'Farrell of St. Vincent's Hospital, and is a most valuable one. The prolonged chloroform inhalation was also most remarkable, having been sustained on one occasion for twelve hours. The cure of the disease was complete.

Reports of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 14TH, 1865.

JAMES ALDERSON, M.D., F.R.S., President, in the Chair.

ANEURISM BY ANASTOMOSIS OF THE SCALP, TREATED SUCCESSFULLY BY SETONS AND LIGATURE OF THE COMMON CAROTID.

BY GEORGE SOUTHAM, F.R.C.S.

THE patient, a married female, aged 28, had been suffering from the disease for upwards of eight years. She became an in-patient of the Manchester Royal Infirmary in May 1864. The temporal artery and its branches, with the exception of those distributed around the eye and forehead (which, though visibly distended, were not pulsatile), were much enlarged, some of them almost to the size of the little finger, and communicated to the hand a distinct arterial thrill. The occipital artery and its branches were also similarly affected in a less degree. Pulsation was only slightly checked by pressure on the trunks of these vessels, but was completely suspended by compression of the common carotid. An ulcer had formed over the parietal protuberance, which had bled rather freely on several occasions. An attempt was made to remove the lint from the ulcerated surface; but arterial hæmorrhage supervened to so great an extent that the bandages were immediately replaced. On the following day, having taken the precaution to have the requisite appliances for the arrest of hæmorrhage at hand, the compress was removed in the presence of several members of the hospital staff. Profuse hæmorrhage followed from the ulcerated surface, which occupied a space of about an inch and a half in diameter. Pressure with the fingers failed to stop the effusion of blood, escaping as it did from countless sponge-like orifices.

Lint steeped in a solution of perchloride of iron was also applied, and the carotid compressed; but the blood continuing to flow, Mr. SOUTHAM, with the consent of his colleagues, placed a ligature on the trunk of the common carotid, which had the desired effect. Seven days after the operation the vessels of the scalp were soft, flaccid, and apparently bloodless; but very feeble pulsation could be felt in the course of the temporal artery. Four setons of worsted, about four inches in length, were now passed through the vessels, one across the temporal fossa, the others through the parts of the scalp where the vessels were most distinct. The week following, some of the vessels near the original sore were found distended, and slightly pulsatile. Three setons were inserted through them, and another about a fortnight afterwards at the posterior part of the occiput, where a vessel about an inch and a half in length could be distinctly traced pulsating slightly. From this period the case proceeded satisfactorily, and on August 12th she left the hospital quite well, with the exception of a small ulcer at the back of the ear, which was the remains of a slough that had taken place in that part. At the end of December there were no signs of any return of the disease.

The author remarked that the success of the plan of treatment adopted in the above case afforded a prospect of bringing this hitherto unmanageable complaint more effectually under the control of the surgeon. At the time of the patient's admission into the hospital, the disease had arrived at a stage when prompt measures were absolutely necessary for the preservation of life. Accordingly, on the supervision of hæmorrhage, ligature of the carotid was immediately resorted to. But the unfavourable results which have frequently followed deligation of the carotid for aneurism by anastomosis of the scalp induced the author not to rely solely on that method of treatment; and the further progress of the case showed that if other means in addition had not been employed, no permanent benefit would have resulted from the operation. This need excite no surprise, for the operation to be successful must either permanently cut off the circulation through the diseased vessels, or lead to their obliteration—conditions which, however probable when the disease is confined to a single vessel and assumes the ordinary form of aneurism, are not likely to follow when several are affected, as in the present case, involving the entire temporal system, with its arteries, veins, and capillaries. For the blood in the vessels after deligation does not coagulate, but readily finds its way into the general circulation, and the vessels remaining unchanged, become again distended as soon as the circulation through the anastomosing branches is re-established. But, despite these drawbacks, deligation, even when not required for the suppression of hæmorrhage, has its advantages; for the temporary interruption which it causes to the circulation through the diseased structures affords a favourable opportunity for the application of other remedies. Setons were therefore resorted to as soon as there were indications that the scalp was supplied with blood sufficient for reparative purposes. They were applied at intervals wherever any return of pulsation showed itself.

Setons have so repeatedly failed, that their success in the present instance must be attributed to the quiescent state of the circulation produced by the ligature of the carotid. In confirmation of this view, the author referred to the case of a young lady who was under his care several years ago, whose index finger and thumb had become, through enlargement of the vessels, twice the natural size. Some of the vessels were in circumference as large as goose-quills,

and gave a livid-bluish appearance to the fingers. Not the least pulsation or arterial thrill could, however, be discovered; and the vessels could be partially emptied of their blood by pressure. Three fine worsted setons were passed from the hand to the apex of the finger. Others were inserted at intervals. At the end of six months all evidence of the disease had disappeared. Deligation of the arteries, therefore, prior to the insertion of setons, does not appear necessary in all cases of aneurism by anastomosis. The disease is an affection of arteries, veins, and capillaries, varying in its characters according to the extent to which each of these structures is implicated. Deligation, therefore, seems to be required where the arterial tissue is principally involved, or where the enlargement of the capillaries has taken place to such a degree as to enable the force of the heart's action to communicate its impulse through the capillaries to the blood circulating in the veins. Similar considerations will also determine the extent of deligation, which, except where severe hæmorrhage occurs, need, in the majority of cases, only be applied to the smaller arteries.

Though setons were employed in the case now related, yet galvanism, the injection of perchloride of iron, and other similar agents, may, in some instances, perhaps, be advantageously substituted; and even the risks attending ligature of the arteries may, by instrumental or digital compression, be occasionally obviated.

The PRESIDENT said that tying the carotid seemed a severe operation for a disease so limited. He considered that photographs shewing the character of the disease before and after the operation would have been of value.

Dr. SIBSON regretted that Mr. Southam was absent through illness; and observed that the carotid was tied, not to cure the disease, but to arrest hæmorrhage. The operation was successful, and the treatment by setons thereby much advanced.

Mr. C. H. MOORE also observed that the tying the artery was to arrest arterial hæmorrhage, and not to cure the disease. For some aneurisms of this kind, ligature of the vessels would not be necessary; while in others, the abundance of large arteries might demand this proceeding. A case which he had seen, under Mr. De Morgan's care, had been healed by setons passed by needles, over which were placed caoutchouc rings, and by threads charged with perchloride of iron. The result was the cure of the patient; who, five years afterwards, had no trace of the aneurism, but an abscess occupying its site. In vascular tumours of the scalp in children, which sometimes attained a very large size, if a large vessel were open and could not be tied, it would be necessary to apply a ligature to the main artery.

Mr. SAVORY said that the success of Mr. Southam's case would encourage surgeons to tie a vessel at a distance when the injured point could not be reached.

CONGENITAL HYDRONEPHROSIS, IN A BOY FOUR YEARS OLD, REPEATEDLY TAPPED: RECOVERY.
BY THOS. HILLIER, M.D.

The patient was born with great enlargement of the abdomen, simulating ascites, for which it was mistaken till he was nearly four years old. It was then ascertained to be an enormous cyst springing from the right lumbar region. From its great size it caused difficulty of breathing and prevented his walking. The cyst was tapped in front, and 102 fluid ounces of clear non-albuminous fluid were drawn off, having all the characters of dilute urine. The fluid rapidly re-collected, and on a second tapping was found to be albuminous and purulent, but still to

contain a considerable quantity of urea. Attempts were made to establish a permanent fistula anteriorly, and then posteriorly; but on each occasion the fluid after a time ceased to flow. Much irritation and depression followed the several tapplings, so that the patient's life seemed to be endangered. After one of the operations a quantity of fluid was passed from the bladder exactly similar to that from the cyst, and quite unlike what was usually passed from the urethra; a temporary communication thus obviously being established between the cyst and the bladder. The patient has now been left without operation for some months, and has regained his strength; but the cyst remains, varying from time to time in size, and his urine is often purulent and fetid. It is presumed that there is some congenital malformation of the right ureter which renders it liable to occlusion, but admits, under some circumstances, of the passage of fluid.

Cases of congenital hydronephrosis due to obliteration of the ureter were quoted, proving fatal in infancy; one a case of an enormous cyst, apparently a dilated kidney, from obliterated ureter, in a woman who lived to the age of twenty-three years; and one of double hydronephrosis in a youth who lived to the age of seventeen years. In the latter case the ureter on one side was much constricted, and on the other entered the pelvis of the kidney obliquely, and was guarded by a valvular obstruction.

Expectant treatment, the author observed, seems to be the only measure indicated. Extirpation of the cyst is inadmissible from the dangers of the operation, owing to proximity to the sympathetic ganglia, and to the liability to hæmorrhage and peritonitis. Tapping was recommended in case of distension so great as to endanger life. It would seem that when the distension reaches a certain point, the ureter allows of fluid to pass down it.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, FEB. 3RD, 1865.

G. POLLOCK, Esq., President, in the Chair.

ON SYPHILITIC DISEASES OF THE SKIN FOLLOWING VACCINATION. BY G. NATLER, ESQ.

THE author commenced by stating that syphilitic diseases of the skin were to be determined rather by the character of the affection than from information to be obtained from the patient; and that these affections deviated more or less from the true type of the diseases to which they belong, the imperfectly formed scales in the squamous diseases being an instance. The diagnosis, also, was assisted by the consideration that these diseases appeared at three periods of life; first, a few days or weeks after birth—the congenital form; secondly, at the period of the second dentition; and thirdly, at puberty.

After a few remarks regarding the transmission of syphilis by vaccination, and the arguments of Mr. Simon against its probability, three cases were related of this disease.

The first patient was aged 22 years, the youngest of seven—all in good health. Her father died of phthisis. After three months, she was vaccinated in the left arm; but the pustule did not heal. Inflammation ensued, and subsequent ulceration, which spread, exhibiting the characters of syphilitic lupus. In the front of the arm, numerous cicatrices were to be seen, of an irregular form; and there were tubercles in various parts, including the face, to which latter place the disease spread eight or nine years since. She derived great benefit from the bichloride

of mercury and iodide of potassium, and from the local application of arsenical escharotics. The patient was exhibited to the Society.

The second patient, E. M., 15 years of age, was the youngest but one of five. She was vaccinated a year ago. The pustule remained in a healthy state for some time, leaving a large and deep scar after healing. Psoriasis soon afterwards made its appearance on the lower extremities and upper parts of the body. It assumed the form of psoriasis guttata; but, the scales being badly formed, it was diagnosed as being of a syphilitic origin. She was benefited by the same treatment as in the first case.

The third case, 19 years of age, was exhibited to the Society. The scalp had been a mass of ulceration, and portions of bone had been removed in a necrosed state. At the present time, there was some offensive discharge and the remains of extensive disease, and there were soft tubercles about the ears and bridge of the nose. She had evidently been much improved by treatment. She had never menstruated, and had been much out of health. Her history was, that she had been vaccinated when three months old; that the pustules ulcerated, and did not heal for twelve weeks. At 14 years of age, a serpiginous ulceration first attacked the scalp. In this, as in the other cases, no trace of syphilis could be found in the parents. She was treated with mercurial vapour-baths, iodide of potassium, and sarsaparilla.

After referring to the Rivolta cases, and the previous good health of the above patients before vaccination, with the appearance of the scars left by it, and after examining all the sources from which the syphilitic poison could be derived, the author terminated by saying, that perhaps nothing had left the point at issue so long in abeyance, or contributed to cast such discredit on the idea of syphilis being received from vaccination, as its rarity and the acknowledged difficulty of maintaining unbroken the chain of evidence between the effect of syphilis and its real origin. Admitting the results stated to be occasionally dependent upon vaccination, they yet scarcely affected the more general question of its utility.

THE NIGHTINGALE FUND. The trustees of the Nightingale Fund are well satisfied that money need not stand in the way of the training of any number of young women for service in hospitals or anywhere else. The demand is so great that money for the purpose is always forthcoming, if the candidates can be got, after the fund has distributed its income. That fund at present maintains and trains in St. Thomas's Hospital 18 women between the ages of 25 and 35 for at least a year each. Thus far the eagerness to secure them at the year's end has been such that all have been immediately placed, and may be considered provided for for life. As many more are received as can be employed and trained in proportion to the number of patients; and of these the expenses are paid by private patrons. In the last report of the Nightingale Fund it is stated that the lowest salary received by any hospital nurse of their pupils is £20 a year, and maintenance in everything but clothes. This lowest pay is certainly not high, being about equal to that of a provincial cook, or a good housemaid; but it is the lowest, while it includes an amount of personal comfort, and a permanence and security of employment, which the humble governess and the milliner's journeywoman can never hope for. In private practice a skilled nurse may evidently demand her own terms; and a rich field of enterprise remains for those who, being trained, become the trainers of others in the new schools which will be rising up everywhere. (*Cornhill Magazine.*)

Correspondence.

SYPHILISATION AS A MEANS OF CURING CONSTITUTIONAL SYPHILIS.

LETTER FROM PROFESSOR BOECK OF CHRISTIANIA.

No. II.

SIR,—In reference to the gentleman cured under my care of tertiary syphilis by syphilisation, let me further observe that Mr. Lee, imagining he has shown that this patient has never had syphilis at all, supposes, of course, that I did not inoculate him with matter from an indurated syphilitic chancre. On this point, also, I am compelled to differ in opinion from Mr. Lee. During the last eight years, I have used *matter taken from indurated sores alone* for my treatment by syphilisation. Mr. Lee will perhaps answer to this, that matter from a hard chancre cannot produce pustules on a person suffering from constitutional syphilis. It is true, that this opinion is at present entertained by many surgeons; but it is not, therefore, a correct one; and in various places this doctrine is beginning to be abandoned. My experience proves it to be erroneous. I do not intend to dwell on the history of this doctrine, which is well known to the readers of your JOURNAL. I shall only state what has been done here in Christiania towards answering this question.

Dr. Bidenkap has for several years inoculated with the discharge from indurated chancre, and has found that when the chancre does not secrete pus there is no result, or that, after a long time of incubation has elapsed, a papula appears, which afterwards becomes excoriated. If, on the other hand, the chancre be brought to suppuration by means of an irritant, it may be possible, by inoculating with the matter thus obtained, to produce pustules in a short time. In both cases, it is often necessary to repeat the inoculation several times before any result takes place. Mr. Lee is himself well acquainted with the manner of performing these inoculations. The idea of irritating the chancre to make it produce pus, has also occurred to him, and he had done so previously to Dr. Bidenkap's attempting it; but Mr. Lee, by his inoculations, only caused adhesive inflammation, and, having once produced a pustule, imagined he had inoculated from a "*chancre mixte*". Dr. Bidenkap was the first to produce pustules and chancre-sores with matter both from indurated chancres and from mucous tubercle; and to use the matter from these sores to continue inoculation. Melchior Robert of Marseilles has done the same; as also Köbner of Breslau; and, as I have heard, Hebra of Vienna.

As before stated, the matter which I have used during the last eight years for syphilising my patients, has been taken *solely* from indurated chancres. It was with this matter that the patient who has given rise to this discussion was inoculated. It was by means of these inoculations that this gentleman, who, when he came here, appeared to be at death's door, daily

improved, so that in two months he was able to go out shooting.

Instead of endeavouring to reason away such a plain fact, and blindly running down syphilisation, it would have been better had Mr. Lee sought for reliable information respecting this mode of treatment, which can do more with syphilis than all the mercury and iodine in the world.

I am, etc.,

W. BOECK.

Christiania, March 4th, 1865.

SYPHILISATION.

LETTER FROM HENRY LEE, ESQ.

SIR,—Professor Boeck has been good enough to send a first letter on the subject of syphilisation, and to refer to some observations made by me in your JOURNAL of the 4th of February. The objections of Professor Boeck to the observations in question have already been either directly or indirectly answered in my reply to Dr. Simpson published in the JOURNAL for February 18th. It appears, therefore, unnecessary that I should at present occupy your attention further than to state that Dr. Boeck has fallen into the mistake of supposing that I had given it as my opinion that the patient who was under his care was suffering from "softening of the bones". This formed, certainly, no part of the opinion which I expressed.

I am, etc., HENRY LEE.

2, Savile Row, April 1st, 1865.

MEDICAL EVIDENCE IN RAILWAY ACCIDENTS.

LETTER FROM DANIEL NOBLE, M.D.

SIR,—Your leading article in this day's number of the JOURNAL, on "Medical Evidence on Railway Accidents", is very opportune, particularly as supplying the occasion for some discussion on the right position which members of our profession should take, when forensically occupied in reference to these cases.

Having myself for some years been much consulted in circumstances of this kind, sometimes by the plaintiff in actions for compensation and sometimes by the defendant, I have naturally been led to reflect upon this question in most of its bearings; and, for this reason, I must solicit a portion of your space for the expression of such practical views as I have been led to form.

Concerning the duties and the position of railway medical officers, I have but little to say; I was never one of their body, and their ability to speak for themselves is beyond dispute. It may yet be observed that the heavy responsibilities of railway companies, and their liability to become the victims of imposture or of culpable exaggeration, renders it imperative that they attach to their interests skilled medical men, without whose professional services the shareholders would have but little protection against subtle attorneys who have mendacious clients.

But concerning the position of independent members of the profession having to do with railway accidents in their legal consequences, I would respectfully offer a few practical suggestions as to the duties devolving upon them, and as to the course in detail which it may be alike just and expedient for them to take under the circumstances in question.

However the distinction may sometimes be lost sight of in practice, it will, of course, be conceded that no medical man, summoned as a witness, can rightly give his evidence in the spirit of an advocate.

When such evidence is called for by the requirements of justice, the medical witness, whether stating facts or opinions, has simply to tell the truth; and if, during examination, he suppress information within his knowledge, or wilfully exaggerate or extenuate, in a way to affect unduly the question at issue, he may compromise himself very painfully. The position itself, in many instances, furnishes, undoubtedly, some temptation to a sort of semi-conscious wrongdoing in these particulars; but this temptation, I conceive, would be removed, or greatly lessened, by adopting the course which has always been my own, and which, whilst very simple, is obviously the just and prudent one.

When a medical man is consulted in cases likely to become the subject of litigation, he soon has intimation that he may be required to give evidence; and lawyers, from a certain fashion of speech, will sometimes talk to a medical man about "engaging his services as a witness." Now, plainly enough, the right proceeding in these circumstances is to repudiate such a position, whether expressed or only implied. You may profess yourself ready to give your opinion of a case in writing; but that, as to giving evidence, your opinion may or may not promote the interests which the lawyer has in his keeping. Now is the time, before the feelings have become much engaged in the legal conflict, for making a calm and dispassionate record of your professional judgment; and if, after doing so, you are summoned as a witness, the way is plain. You have to communicate in court what you have already set forth under less formidable circumstances; the party that calls you knows what he has to expect; and the medical witness need to have no apprehension, as to what may be thought of his evidence in its effects upon the case.

Your readers, I trust, will acquit me of egotism, if I say a few words as to the way in which this proceeding has worked in my own experience. Actions have sometimes been settled upon the best terms that could be procured, when my reports have not corroborated the expectations set up by the representations of a plaintiff; and when cases have proceeded to trial, it has several times happened that, although summoned, I have not been called as a witness, because the "side" would not be benefited by any evidence that I should give.

Now, there is a concerted action that can often be taken, which, whilst it is most conducive to the ends of justice, is, at the same time, conservative of the honour and the dignity of our profession. It is this: for the medical men regarded as being in the interest of both plaintiff and defendant, frankly to meet for discussion of the whole state of affairs, so far as medical; to exchange the results of their common experience, and to balance probabilities as to the issue of the case. In a proceeding of this kind I have many times shared, and almost invariably with a complete conciliation of any primary difference of opinion, and a consequent avoidance of that unhappy discordance of medical judgment so grateful to "outsiders", but so humiliating to the profession itself. Of course, to render this last suggested course practicable, there must, with all persons engaged, be mutual respect and confidence, no foregone conclusions, no assumption either of "undoubted importance" on the one side, or of "disastrous mischief" on the other; but the same courtesy, and the same reciprocal concession of honesty of purpose, as we find to obtain in ordinary medical intercourse under circumstances of professional consultation.

But the subject I find is a very extensive one—one, indeed, that is susceptible of indefinite expansion. Not wishing further to encroach upon your space, I

will conclude by the expression of a hope that the question may receive some adequate discussion in future numbers of the JOURNAL.

I am, etc., DANIEL NOBLE.

Manchester, March 25th, 1865.

PROSECUTIONS OF MEDICAL MEN.

SIR,—I have been waiting some time, from one at least of your many correspondents, for a scheme or method whereby the constantly recurring prosecutions of medical men and impeachment of professional character may be more readily met and effectually dealt with, and by which the profession at large may be able to know, from authoritative sources, the exact nature and extent of injury sustained in any case, as well as the amount of pecuniary aid and exertion necessary to vindicate the injured party and protect him from loss. At present, this question is in the utmost uncertainty and irregularity of action, with but little opportunity of the profession being fully informed of the circumstances calling for its attention and interference.

A plan, therefore, to remove these difficulties, and secure other objects of greater magnitude to the commonwealth of medicine, is an important desideratum. This, I conceive, will be attained by each Branch of the Association appointing an Ethical Committee, to be elected yearly with the other officers, and chosen, if possible, from distant localities in the Branch; so that any transaction or occurrence demanding professional notice or inquiry would be immediately known to one of them, and communicated to his colleagues. Whether the parties concerned were members of the Association or no, should not be a matter of import; if they were not members, the offer of friendly interference or defence would be a strong incentive to their becoming so. The number of five or seven for each Branch might suffice; and each Committee should meet where and as often as might be deemed requisite, and have power to call a meeting of the Branch for its advice and counsel in any emergency.

This method of procedure, it will be seen, will at once relieve that most embarrassing and painful position to an upright man—the necessity of standing alone in self-vindication against a false and grievous charge. The task of defence being undertaken or supported by his brethren will be proof that the brotherhood of the profession is no longer a name. The Committee of the Branch will see any member protected as far as possible from wrong or unjust accusations, and will be always near to give him advice in difficulty or trouble. Had such machinery been in existence in the Metropolitan and Lancashire and Cheshire Branches when the distressing cases of Mr. Adams and Dr. Waters were before us, how much perplexity and painful embarrassment would have been saved to these gentlemen! and, in the instances which have since transpired, how much trouble, difficulty, and probably expense, avoided!

It is needless here to allude to the comparative disadvantage of private Committees, formed to defend or sustain the character of a friend; for, however well supported by zealous and well directed exertions, with the aid of social influence and great personal sacrifice, they too often issue in disappointment and inefficiency. The knowledge, besides, that the public will immediately have, that the rights of an injured and unjustly accused member of the profession will be defended by the whole body, will be the strongest check and restraint against those attacks which have of late become so alarmingly frequent. The same Committees would likewise devise the best means of creating a protection fund; and,

no doubt, more economically to the profession than by the special appeals often made to it.

This is not the first time the value and policy of forming Ethical Committees for many important purposes have been suggested, if not urged, upon the Association; but the present would seem a most favourable one for their adoption. By these simple measures, the reconciliation and adjustment of misunderstandings, and of the unhappy collisions, too frequently occurring among medical men, will often be effected and kept from public notice, and will enable the profession at all times to defend itself, without individual prominence or responsibility, against great outrage or misrepresentation, from whatever quarter it may come.

Lastly, these Committees will best consider and settle, by correspondence, the *vexata questio* of medical charges; and by the same powerful agency, carried to its legitimate end, will be able, in due time, to produce a comprehensive code of medical polity and ethics.

Hoping the members of the Association may see this subject in the same light with me,

I am, etc., AN OLD MEMBER.

Manchester, March 25th, 1865.

TREATMENT OF HERNIA.

LETTER FROM H. E. NORRIS, ESQ.

SIR,—Mr. Steel's two most interesting cases of hernia remind me of cases which have occurred in my own practice, as well as of the treatment which of late years I have found to be most successful in that of strangulated hernia generally.

Having frequently noticed the good effect arising from the administration of large doses of tincture of opium in cases of enteritis, I determined to try the same remedy in cases of hernia where strangulation existed, as I believed the good effect to depend on the degree of quietude in which the inflamed part was kept by the sedative influence of the laudanum on the muscular coat of the bowel.

Accordingly, when such cases arose, having in vain tried the taxis, and the symptoms of strangulation being urgent, I gave the patient (an old woman of seventy and upwards) a mixture containing drachm doses of tincture of opium; one dose to be taken every hour till three doses had been taken. I directed the medicine to be given at intervals of two hours, if the third dose did not produce the desired effect—viz., the reduction of the tumour. On calling to inquire for the patient some hours afterwards, I was told that the third dose had relieved her, and that she was quite easy and comfortable. On examination, I found the hernia, which was femoral and small, quite reduced; and the operation, which I had looked forward to as almost certain, was thus rendered unnecessary.

I have on several occasions found the like treatment equally successful, and give you the result of my experience, hoping it may prove of the like benefit to others.

Even when the vomiting has been constant and distressing, perseverance in the use of the medicine has proved effectual, being in the end retained on the stomach; and this in cases where the taxis had quite failed to relieve the patient. The application of cold (ice, if procurable) is a most useful auxiliary to the above treatment. The dose of laudanum given above is the largest I administer, and is most suited to old patients. For the young and middle-aged, I should recommend a smaller dose.

I am, etc., H. E. NORRIS.

Charmouth, March 24th, 1865.

Medical News.

BIRTH.

COLLINS. On March 31st, at Chew Magna, Somerset, the wife of *Charles Howell Collins, Esq., of a son.

MARRIAGES.

ALEXANDER—BORTHWICK. At Greenside, Leslie, by the Rev. John Logan, of the Free Church, James Alexander, Esq., Surgeon, Leslie, to Janet, second daughter of the late Hugh J. Borthwick, Esq., Kirkcaldy.

DAVIS—LOW. On March 29th, at the Parish Church, Wrexham, by the Rev. James Dixon, assisted by the Rev. T. J. Jones, Incumbent of Minera, Edward Davis, Esq., M.D., to Alison Paxton, eldest daughter of William Low, Esq., Lloftwen, near Wrexham. No cards.

ROYAL INSTITUTION. On Saturday, April 8th, at three o'clock, Professor Marshall will deliver a lecture On the Nervous System.

TESTIMONIAL TO MR. SPENCE. The pupils of Mr. Spence, the successor of Professor Miller in the chair of Surgery in Edinburgh, have recently presented him with an album containing the photographic portraits of the gentlemen who had attended his class.

UNIVERSITY OF LONDON. The election of examiners for degrees, etc., in the University of London, is fixed for Wednesday, the 26th inst. Amongst others, the following vacancies are announced:—One in experimental philosophy; one in chemistry; one in botany and vegetable physiology; two in geology and palæontology; one in physiology and comparative anatomy; two in midwifery; one in materia medica and pharmaceutical chemistry. The other examiners offer themselves for re-election.

THE HOLBORN UNION. The Committee of the Guardians of Holborn Union appointed to consider Mr. Farnall's recommendations have reported to the effect: That the salary of the medical officer should be raised from £100 to £135; that a paid nurse should be appointed by way of experiment; that the medicines and drugs are as good as need be; and that the Guardians should supply cod-liver oil. The report has been adopted with one exception—the salary of the medical officer being raised to £125, and not to £135.

MEDICINES FOR THE POOR. In the House of Commons lately, Sir J. Shelley asked the President of the Poor-Law Board whether the Poor-Law Board intended in this session to take any, and if any what, steps to carry out the recommendation of the Select Committee on Poor Relief, that in future cod-liver oil, quinine, and other expensive medicines should be provided at the expense of the guardians, and not as heretofore by the parochial medical officers. Mr. Villiers said the subject referred to was one to which the board had given much consideration, and on which they had communicated much with guardians in different parts of the country, and they did not despair of inducing them very generally to adopt the recommendation of the committee in question. There were difficulties in the way, however, owing to the existing contracts with the medical men, which were made on the other system. These contracts usually were made for life, and there had sometimes been an unwillingness to revise them; but in certain cases the doctors did not live in the union, and were then selected annually, and in all these cases there was reason to hope that the recommendation would be adopted. The Poor-Law Board in such cases would use all its authority to induce the guardians to adopt it.

MORTALITY IN EMNETH. On Friday week, Dr. Brady asked the Secretary of State for the Home Department if his attention had been directed to a statement made by the coroner at an inquest held at Emneth, in the county of Norfolk, and reported in the *Lynn Advertiser* on the 25th ultimo, directing attention to the extraordinary mortality among children in Emneth, amounting to 80 per cent. of the population, which the parish surgeon attributed to gross and culpable neglect, the children dying from starvation. Sir G. Grey said he had received a letter from the coroner, stating his belief that the great mortality among the children was attributable to the neglect of the mothers. The letter had been forwarded to the High Constable of the county, who would inquire into the facts.

OPERATION DAYS AT THE HOSPITALS.

MONDAY......Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

ESTABLISHED 1849.
MEDICAL TRANSFER & PROFESSIONAL AGENCY.
50, Lincoln's Inn-fields, W.C.

Mr. J. Baxter Langley, M.R.C.S.

(KING'S COLLEGE), has now upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements, and no expense incurred (except in special cases) unless a negotiation be completed.

The General Partnership and Commercial Agency business lately recently conducted by him at his City offices, and his experience in the management of large commercial undertakings, combined with his professional acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned.

Mr. Langley can refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers, and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.
Office Hours, from 11 till 4; Saturdays from 11 till 2.

Competent Assistants provided

without delay, free of expense to the Principals. No gentlemen recommended whose antecedents have not been inquired into. Apply to Mr. Langley, 50, Lincoln's Inn-fields, W.C.

Locum Tenens can be despatched

by an early train, after receipt of letter or telegram, stating terms, duties, and qualifications required.—Fee, 10s. 6d. Address Mr. Langley, as above.

In a good Market Town.—For

Transfer, an excellent Practice, income £500, increasing. No Midwifery at present, but the receipts could be raised to £800 or £1000 by a gentleman competent to undertake obstetric practice. Terms very moderate, the vendor being compelled by family circumstances to remove. Address "S. 1055," Mr. Langley, as above.

Birmingham General Dispensary

—The Office of JUNIOR RESIDENT SURGEON is now vacant by the resignation of Mr. GEORGE ELKINGTON, Jun.

Candidates for the Appointment are required to send in their Diplomas and Testimonials, addressed to the Secretary, on or before Friday, the 25th of April next.

The Election, which is vested in the Committee, will take place on Wednesday, the 3rd day of May next.

Salary £100 per annum, with Furnished Rooms, Fire, Lights, and Attendance. In consequence of the extension of the district, the keep of a horse will be allowed.

The Committee will, on the same day, appoint an additional JUNIOR RESIDENT SURGEON at a Salary of £50 per annum, with Furnished Rooms, Fire, Lights, and Attendance.

Candidates are required to send in their Diplomas and Testimonials on or before April 25th.

LAW XXXIII.

The Resident Surgeons shall each possess a Registered Qualification or Qualifications from some corporation or corporations in the United Kingdom examining in Medicine, Surgery, and Midwifery.

A preference (*caeteris paribus*) will be given to such Candidates as will undertake to continue in office at least two years.

JOHN GARNER, Senior Resident Surgeon and Secretary.
March 15th, 1865.

Diabetes. — Blatchley's Bran

BISCUITS, prepared according to Dr. CAMPLIN's prescription, are perfectly free from starch and sugar, very nutritious, and easily digested. See CAMPLIN on "Diabetes," third edition. Price 1s. 6d. per lb.; or in boxes at 5s., 10s., and 20s. each.

EDWARD BLATCHLEY, CONFECTIONER, 362, OXFORD STREET, three doors from the Pantheon, London.—Orders to be accompanied by a remittance.—E. BLATCHLEY supplies the London, Guy's, St. Thomas's, the Royal Free, Charing-cross, Cambridge, Nottingham, Bury St. Edmund's, Ashton-under-Lyne, Liverpool, Royal Naval, Oxford, Norwich, Suffolk, Lynn, Royal Isle of Wight, Gloucester, Haslar, the German, and other Hospitals.

Royal College of Physicians.—

LECTURES will be delivered at the COLLEGE, Pall Mall East, at Five o'clock on each of the following WEDNESDAYS and FRIDAYS.

DR. ODLING....APRIL 26, 28; MAY 3, 5, 10, 12.
ON THE CHEMISTRY OF TISSUE-METAMORPHOSIS.

DR. HYDE SALTER....MAY 17, 19, 24.
ON THE DIAGNOSTIC VALUE OF THE VARIOUS FORMS OF DYSPNEA:

An inquiry into the laws of the perturbations of the respiratory movements; with an account of an instrument for rendering those movements and their perturbations self-registering.

DR. LIONEL BEALE....MAY 26, 31.
AN INQUIRY INTO THE NATURE OF THE PHENOMENA WHICH CONSTITUTE 'INFLAMMATION'.

1. Of the doctrine of 'Irritation'. Of 'Inflammation' in tissues destitute of vessels. Of the formation of Lymph and Pus.
2. Of 'Inflammation' in vascular structures, and of certain conditions which favour or interfere with the inflammatory process.

(By order of the President.)

1865.

W. COPNEY.

St. George's Hospital Medical

SCHOOL—The SUMMER SESSION commences on MONDAY, MAY 1.

LECTURES.

Midwifery—Dr. Robert Lee, F.R.S.

Materia Medica—Dr. Barclay.

Practical Chemistry—Dr. Noad, F.R.S.

Botany—Dr. Maxwell Masters.

Medical Jurisprudence—Dr. Fuller.

Pathology—Mr. Henry Lee.

Dental Surgery—Mr. Vasey.

On the payment of a compounding fee of £100, a pupil becomes perpetual to the Practice of the Physicians and Surgeons, and to all Lectures, may compete for all Prizes, Exhibitions, and for the Office of House-Surgeon, Medical and Surgical Registrar, and may become Clinical Clerk and Dresser for two periods of three months each.

On the payment of £50—one half, £45, to be paid at the commencement of the First Summer Session, and the other half, £45, at the commencement of the Second Summer Session—a pupil will be admitted to the Hospital Practice and Lectures required for Examination by the various Examining Bodies.

Gentlemen can enter to the Hospital Practice and Lectures separately, or to any one Course of Lectures.

The Hospital contains 350 beds. Clinical Lectures are delivered by the Physicians and Surgeons every week.

A MATERNITY DEPARTMENT, for the delivery of married lying-in women at their own homes, is established at the Hospital; and a Ward is devoted to the reception of women suffering under diseases peculiar to the sex.

The following Prizes will be awarded at the termination of the Session:—

Sir Charles Clarke's Prize for Good Conduct.

The Thompson Medal.

Sir Benjamin Brodie's Clinical Prize in Surgery.

The Lewis Powell Clinical Prize in Medicine.

The Henry Charles Johnson Memorial Prize in Anatomy.

A General Examination will be held at the end of the Session, and a Certificate of Proficiency given to each Pupil who passes to the satisfaction of the Examiners, and the following Prizes to the most distinguished, viz.:—

A Prize of Ten Guineas to Pupils in their First Year.

A Prize of Ten Guineas to Pupils in their Second Year.

A Prize of Ten Guineas to Pupils in their Third Year.

Further information may be obtained from Dr. Barclay, the Treasurer of the School, from any of the Lecturers, or from Mr. Hamerton, at the Hospital.

Important Notice to the Profes-

SION.—PATENT (COOKED) FOOD, for INFANTS and INVALIDS.—DR. RIDGE'S PATENT.—The best wheaten flour is put into the apparatus, where every particle is brought under the uniform temperature of 212° for eight hours, which thoroughly cooks it; and as all moisture is driven off, the nutritive quality of the flour is largely increased, while it is so light and digestible that the powers of the feeblest stomach are not taxed, but can easily appropriate it. A sample for examination will be forwarded free to any medical man who may desire it.—Manufactory—Horslydown, London, S.E.

Salmon, Ody, & Co., most re-

spectfully inform the Public that their PATENT SELF-ADJUSTING TRUSSES are found to answer the purpose with more Ease and Security than any other Invention, requiring no under-trap or any galling Bandage. Persons in the country are requested to send the circumference of the body one inch below the hips, and to observe that "Salmon, Ody, & Co." is stamped upon the leather case. A female attends by appointment.

MANUFACTORY, 92, STRAND, LONDON.

Observations

ON THE

CÆSAREAN SECTION AND ON OTHER OBSTETRIC OPERATIONS.

BY

THOMAS RADFORD, M.D.,

F.R.C.P. EDIN. AND F.R.C.S. ENG., ETC.,

HONORARY CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL,
MANCHESTER.

CHAPTER VIII.

Symphysiotomy and Mechanical Dilatation.

I HAVE now to speak of two propositions intended to supersede the Cæsaean section, and which cannot be included under either of the former divisions.

I.—*Symphysiotomy.* Symphysiotomy, or a division of the cartilages constituting the symphysis pubis, was advocated by Sigault, and his suggestion was received with enthusiastic approval. A medal was struck off in honour of him.

British obstetricians have discountenanced this operation, because it is not only inadequate to increase the diameters of the pelvis, so as in any way to facilitate delivery when this bony cavity is so contracted as to require the Cæsaean section, but because it would be attended by most dangerous results.

British medical literature has only once been disgraced by the record of the performance of this operation. I have already adverted to Mr. Simmons's proposed compound operation of symphysiotomy and craniotomy.

II.—*Mechanical Dilatation of the Pelvis.* At a late discussion on a case of Cæsaean section at the Royal Medical and Chirurgical Society, which was reported in the *Lancet*, it was stated that a pelvis which was distorted from mollities ossium might be dilated by means of bags introduced within its cavity, and distended by either water or air. It was asserted, that this practice had been adopted in one case with the effect of widening the pelvic space. The President stated that he had found the bones affected with this disease yield during the extraction of the child after craniotomy.

From my own practical knowledge, I can truly affirm the truth of the last statement. Some years ago, I made the fact known to the profession.

In a case, at some distance from Manchester, in which the pelvic space at the brim was about two inches and a quarter, it was deemed right to craniotomise the child. After fixing the crotchet, and adjusting the head in the most favourable position, force was cautiously used, and, after a few extractive efforts had been made, the head gradually descended, during which time the pelvic bones yielded to the pressure, and ultimately delivery was accomplished. Immediately afterwards the pelvis was examined, and found to have regained its former dimensions.

Other cases of this kind have come within my knowledge. One of great interest is briefly related in the *Provin. Med. and Surg. Journ.*, vol. ii, page 706, 1847. Although it is true that the pelvic bones, when affected with mollities ossium, do sometimes yield to the pressure of the child when drawn through the cavity; and although the pelvis, as be-

fore mentioned, may be partially dilated by the mechanical influence of the elastic bag, yet, in my opinion, practical rules cannot be based on such an uncertain event where life is concerned.

Before such a change can be safely effected, a very considerable and an uniform softening must have taken place in the greater number, if not in all, the bones of the pelvis which are subjected to the influence of pressure, whether it be produced by the child or by artificial means. We know very well that this uniform change is found to happen in very few cases. Some of the bones sometimes become very soft, whilst others are comparatively unchanged. In other cases, some of the bones become very soft; whilst others become very hard and brittle. Sometimes, the pelvis becomes very highly distorted, and all its bones are extremely brittle and fragile, as happened in Dr. Murphy's case.

In a pelvis thus changed by disease, what would be the result (supposing it possible to accomplish it) of dragging a full grown mutilated child through its cavity, or of attempting, by artificial and mechanical force, to dilate the pelvis for the purpose of accomplishing the delivery? The bones must be smashed, or at least so much broken, that irreparable injury must be produced. Even assuming that the bones are so uniformly softened as to yield to the pressure, it is quite certain that the increased capacity would only be temporary, as the bones would immediately and most likely completely return to their former position as soon as the pressure was removed.

CHAPTER IX.

The Comparative Value of Maternal and Infantile Life.

The British obstetric principle, which admits the preferential use of the crotchet, or the induction of abortion, is based on a calculation made as to the relative value of the life of the mother and of that of the infant or of the embryo.

It is said, and no doubt truly, that the social relations of the woman are greater than those of the infant. She is endeared to her husband, it may be to her children, and perhaps to her brothers and sisters, besides other kindred and friends. In the abstract, these are weighty considerations, and are calculated to bring conviction to the mind, that her claims for the preservation of life greatly preponderate over those of the infant or of the embryo. It may be stated that these beings are unequal to the mother in organisation, having no moral or religious responsibility, no social ties, no anticipation of their future doom; and further, as regards the latter (the embryo), that it is at the very time drawing its nourishment from the mother's existence, that it has never had a distinct or separate life, and that it is little more than a member of the mother. These arguments, when only abstractedly considered, appear to be true; and to warrant the deduction that the life of the infant or embryo is of little value when compared with that of the mother.

The impulse of natural feeling would probably—nay, nearly to a certainty—induce a man to decide in favour of this proposition. But, in the settlement of a question which involves the preservation or destruction of a human being, neither abstract reasoning nor feeling should be allowed to influence the obstetrician;—conscience, reason, and judgment, ought to actuate him, after having fully and

deliberately considered all the relative and contingent circumstances which either now or in future appertain to the case.

The unfounded and unwise opinions of Dr. Osborne primarily and mainly led a large section of the profession to estimate the life of the infant *in utero* at a very low value. He considered it nearly as a nonentity; as devoid of sensation, and also as nearly deprived of motion. But I think I am asserting the truth when I say that there are few, if any, members of our profession who now entertain such opinions.

According to British practice, the destruction of the infant is not limited to one; but if the cause which required its sacrifice in the first instance be permanent, then in each successive labour, no matter what number, the same operation must be performed. Hence in the end there must be a fearful sacrifice of human life.

The repeated necessity of craniotomy in the same woman demands from the obstetrician serious consideration. In some cases, from one to twelve infants have been destroyed. Can such a procedure be justifiable? The obstetrician should pause; he should reflect. It is a dreadful position to be placed in, to have one's hands imbrued with innocent blood.

The woman is *ipso facto* one party, and indeed the chief party, who has brought into existence the innocent being whose life the practitioner is employed to take away. It may be argued, as a plea for her justification, that the wife is subject to her husband; and there can be no doubt that she has engaged to be so in the matrimonial contract, which was mutual. But if it be considered right (which in such a case as this could only be so conditionally) strictly to observe this promise, it must be equally imperative upon both parties to obey the law of nature and fulfil their mutual pledge to procreate (and without doubt preserve) the species, both of which vows are broken by the employment of the crotchet.

It may again be urged, that both the parties were alike ignorant of any cause (otherwise they were solemnly called upon at the altar to avow it) which would interfere with the great object of matrimony. Therefore, the woman, unacquainted with her physical organic defect, would be entitled to have those measures adopted for her first delivery which would expose her life to the least hazard. Although the comparative safety of delivery by the only two available methods is unsettled by either positive or correct statistical evidence, yet, if she or her husband desire that craniotomy should be performed, then the obstetrician would probably act correctly in performing it.

But, in a second pregnancy, when they are fully acquainted that an unutilized infant cannot be born, the question stands on very different social and moral grounds. The practitioner is here placed in a most responsible and trying position when called upon to decide whether he ought, time after time, or thus repeatedly, be made the agent to take away life. I entertain the fullest conviction that a great proportion of our profession have most conscientious scruples to repeat this revolting operation in the same woman. This destruction of infants, in my humble opinion, can be justified on no principle, and is only sanctioned by the dogma of the schools or by usage.

Dr. Denman had aversions to repeated crotchet-operations. He says: "Suppose, for instance, a woman, married, who was so unfortunately framed that she could not possibly bear a living child by any method hitherto known. The first time of her being in labour, no reasonable man could hesitate to afford relief at the expense of the child. Even a second or a third trial might be justifiable to ascertain the fact of the impossibility." This eminent writer most decidedly erred in even conditionally sanctioning a repetition of this operation. In such cases, the impossibility of delivery of an unutilized infant *per vias naturales* can and ought to be proved by a single case as clearly as by twenty, and when so shown, the Cæsaean section should be performed.

It is by no means to be understood that the life of the infant must never be sacrificed to save the mother. On the contrary, I have already enumerated cases in which craniotomy ought to be performed as an operation of election; but it is not right to destroy the infant on the unfounded assumption that the mother could alone be saved by it; a deduction altogether untrue, and unsanctioned by statistical evidence.

The life of the woman is not, either relatively or comparatively, always of the same value. If she be afflicted with a serious disease, or labouring under some incurable malady, being unfit and unable to discharge her domestic and her social duties, which performance can alone render her life desirable to herself or to her friends, then, under such circumstances, the infant's life ought not to be sacrificed for the mere ideal chance of prolonging her miserable existence, which is a positive evil to herself.

Again, in our estimate of the comparative value of the two lives, we should especially consider whether the cause of difficulty is temporary only or permanent. If it be of the latter character, then the infant's life (except as aforesaid conditionally) ought to be considered higher; and if of the former kind, then we should invariably decide in favour of the mother. The obstetrician should, therefore, endeavour, as far as is compatible with the safety of the mother, to preserve the infant; for I know no case in which an intention or a desire to sacrifice her can ever be entertained, as the especial object of the practitioner should always be to try to save both lives.

When the contingent hazards of craniotomy, and the risk of its abuse are considered, and as we know that the act is the sacrifice of life, and that this awful catastrophe must be often repeated in order to carry out the abstract proposition "to save the life of the woman by destroying the infant"—when we remember the difficulty which in extreme cases is experienced in performing it, the cruelty it inflicts, and many other evils consequent upon it—we may truly wonder that professional men should allow their minds to be haunted by an imaginary Cæsaean spectre, and be so obscured to their own moral and social responsibility. Why should the obstetrician stand in such an unenviable position, not only as an accessory, but *ipso facto* the agent? Again, I ask, ought he to be called upon, and ought he to consent, to victimise poor helpless infants in successive pregnancies, in numbers which make one shudder to recount? Does this remorseless sacrifice of human life correspond with those high moral principles which the members of our noble profession ought to possess?

The eminent Professor of Midwifery in Edinburgh makes the following pertinent remarks. He says: "Formerly medical practitioners seem to have thought little, and medical writers said little, regarding the very repulsive and revolting character of the operation of craniotomy, when performed, as it frequently was, when the child was still living. Apparently, some obstetric practitioners and writers of the present day continue to look upon the practice of craniotomy as one that should not unfrequently be adopted, and one which it is quite justifiable to adopt. Obstetric reports and collections of cases have been published within the last few years describing craniotomy as performed forty or fifty times, or oftener, by the hand of the same practitioner. But, perhaps, ere long, it will become a question in professional ethics, whether a professional man is, under the name of a so-called operation, justified in deliberately destroying the life of a living human being."

Woman naturally is mild, kind, and humane. She is endowed with great fortitude and undaunted courage. She has generally a great desire for offspring, and has a great love for children. Then how can we suppose that any woman with a well regulated mind, if fully aware of her responsibility, could willingly be a consenting party to the repeated destruction of her unborn infants? According to my own knowledge, the case is otherwise. I feel convinced in my own mind that there would scarcely be a woman to be found, who would not suffer any amount of bodily pain to save her infant.

Every woman in whom there exists organic impediment to the passage of a mature or full-grown infant, ought to be at proper time fully informed of the nature and as to the degree of the obstacle. She should also be made acquainted with the alternative operations which are suitable to meet her case. If the obstruction be moderate in degree, then the forceps, turning, or the induction of premature labour, will be proper; but if these means are not available, or if the cause of difficulty is great in degree, then the performance of the Cæsaréan section will be required.

THE NEW DISEASE! Telegrams received from Sir A. Buchanan, St. Petersburg, report that the fevers in that city are believed to have no affinity with the plague, but are attributed to over-crowded lodgings of the labouring classes, spoiled vegetables, and bad water. This is, indeed, only what most sensible persons had already concluded. The number of fever cases admitted into the hospitals varies from 100 to 150 a day, of which the average mortality has been 25 or 30 a day, and the highest mortality 60. The *Paris Moniteur* of Saturday published a note, stating that the Government had made inquiry into the condition of St. Petersburg; and found that, although deplorable some weeks ago, it is now greatly improved, and shows no epidemic beyond the ordinary sickness of the season.

TAPEWORM IN ABYSSINIA. A recent traveller in Abyssinia, Mgr. Van den Deck, has sent to the Belgian Royal Society an interesting account of the tapeworm which so commonly afflicts the inhabitants of that country. They take small doses of kousso only to get rid of the body, when the worm gets of an inconvenient size; but they are anxious to retain the head, for they are terrible gluttons, and having a tenia enables them to eat so much more. The tenia common in Abyssinia is *T. mediocanellata*.

Original Communications.

RETROSPECTIVE NOTES ON OUT-PATIENT PRACTICE.

By C. M. DURRANT, M.D., Physician to the East Suffolk and Ipswich Hospital.

[Concluded from page 318.]

MISCELLANEOUS AFFECTIONS.

The list of those diseases that could be grouped according to their regional situation have been completed; it remains only to enumerate those affections which are of a miscellaneous character, and which cannot be included in the preceding classification.

1. *Anæmia*. The first on the list, as having afforded the largest number of cases, is anæmia. This is a blood-disease, and of very common occurrence among the out-patients of a hospital.

The chief causes of this affection among the poor are insufficient diet, too close confinement, and the existence of those diseases which drain the blood of its red corpuscles, as hemorrhoids, menorrhagia, carcinoma, or any other exhausting discharge.

Among the middle and upper classes, another, and a very rare cause obtains, which is too much overlooked, and too often unheeded, both by practitioner and patient. I allude to the overworking of the brain, which is becoming daily in this age of competition an increasing cause of disease. An exhausted nervous system will as certainly produce an impoverished condition of the blood as insufficient food, or too powerful and prolonged muscular exertion; and cases arising from the former cause, will be found to be more resisting and more unsatisfactory to treat, than those originating in physical disturbance merely.

A few words on the condition of the heart, to which the attention of the patient is so mainly and so distressingly directed, may not be out of place. The irritable action of the organ itself, and the vascular murmurs peculiar to anæmia, are too well known to require comment; but one point, I believe, is not sufficiently attended to, viz.: the importance of making such a thorough examination of the heart and vessels as will enable the practitioner to assure the patient and friends that no disease of the organ exists. I refer to this circumstance from having been so frequently told by anæmic persons that they have been informed that "their heart is not quite right," or "that the heart is slightly amiss." Now all this unnecessarily alarms the patient, aggravates the functional disturbance, and might be entirely prevented by a careful examination, and a faithful explanation of the precise cause of the disturbed action. The vascular murmurs which are sometimes temporarily heard in anæmic cases, both in the subclavian regions and also over the cartilage of the third rib on the left side, are quite distinct from the functional *souffle* and the *bruit de diable*, which is so common an attendant upon this condition of the blood.

Dr. Richardson, in his *Asclepiad* essay upon the former murmur, believes it to arise either from a peculiar condition of the subclavian muscle affecting the artery, or from pressure from behind the vessel caused by local tuberculous deposit. In highly anæmic subjects, I imagine that it may arise from a portion of condensed lung, not necessarily tuberculous, temporarily pressing upon a highly irritated artery, and causing a murmur by disturbing the current of blood through the vessel; or it may arise from

spasm of the walls of the artery, unconnected with pressure.

In the treatment of anæmia, steel of course must be regarded as the chief remedy; but as the digestive organs are often much vitiated, due attention should be given in the first instance to their correction. In administering steel, it should be borne in mind that the more soluble the preparation, the more easily it will be assimilated. In the anæmia arising from an exhausted nervous system, the combination of steel with zinc, and dilute phosphoric acid with very small doses of strychnia, will be useful.

2. *Cachexia*. Closely allied to anæmia, and of which we are seldom without examples, is that peculiarly depraved condition of the blood recognised as cachexia. While anæmia is attributable to a diminution of red-globules, cachexia is traceable to a poisoned condition of blood, chiefly from without, the blood containing also effete matters, that it is unable to throw off. The exciting causes producing the cachectic condition, when not specific, as from syphilis, cancer, or tubercle, may generally be traced to unwholesome atmospheric influences, or to some of the long train of constitutional depressants which operate so surely upon the labouring poor.

Among the most constant of the exciting causes of this deteriorated condition of the general health, may be mentioned insufficient ventilation, and the inhalation of noxious blood-poisoning matters from imperfect drainage. These causes will, I fear, continue to operate until we can convince the working classes of the importance of fresh air by night, as well as during the day, and to which at present, they are most averse; and also to show them the dangerous results which follow prolonged exposure to the effluvia from human and animal drainage, to which they appear equally regardless and insensible.

In the treatment of cachexia, the removal, as far as possible, of these noxious causes of the malady just referred to, will be of the first moment. If the disease be fully established, an improved diet allowing meat and vegetables, with claret or cider, if they can be obtained, will be proper. Attention to the digestive organs, with the chlorate of potash, and afterwards the nitro-muriatic acid, followed by arsenic and cod-liver oil, will all tend to correct the depraved condition of the blood. Thorough cleanliness of the skin (a difficult matter to enforce among out-patients) must also be insisted on.

3. *Rheumatism*. Acute rheumatism, as a rule, is not an out-patient's disease. The forms which it has chiefly presented, have been chronic rheumatism, lumbago, and chronic rheumatic arthritis. The majority of the cases of chronic rheumatism appeared to be quite independent of any previous attack of the acute form of the disease, and were not usually complicated by heart affection. Simple chronic rheumatism very frequently owes its origin to long continued derangement of the digestive organs, with vitiated secretions, producing blood-poisoning; it may arise also from prolonged exposure to wet and cold. One case was clearly attributable to gonorrhœa, and in two or three instances the muscular fibres as well as the tendons were implicated, constituting myalgia.

In the treatment of chronic rheumatism, strict attention should be paid to the digestive organs, for not only will their derangement produce the disorder in the first instance, but it will be impossible to cure it, so long as malassimilation to any extent exists. With this view, I have found nothing better at the onset than the bicarbonate and nitrate of potash with the tincture of colchicum, and spirit of nitrous ether. Although the beneficial influence of colchicum is doubted by some authors, I still think that I have often witnessed excellent results from its use in the

treatment of chronic rheumatism, as distinct from gout. In lumbago, it certainly is very useful. After a time the iodide of potassium, with or without the addition of arsenic, may be advantageously added to the mixture. Cod-liver oil is also a very valuable remedy in all stages of the disease, provided that the stomach be in a state to receive it. As an external application, cotton-wool covered with oiled silk, will generally give ease in the first instance; and afterwards, a succession of small blisters or the iodine paint, applied daily to the affected part, will be of decided service.

In lumbago, a large plaster to the loins, composed of equal parts of opium and pitch plasters, will afford much comfort from its support. If myalgia complicate the attack, rest, a nutritious diet with stimulants, and cod-liver oil with steel, will be the proper treatment.

Chronic rheumatic arthritis frequently commences at the climacteric period in both sexes, and it is then a very obstinate disease. In the severer forms of this affection, whatever treatment may be adopted, the result is too often doubtful; or if improvement obtain, it shews itself very slowly. As a tonic and improver of the blood, I believe that a combination of arsenic and the iodide of potassium with cod-liver oil, will be found the best. As local measures, warm douches with "shampooing," have been strongly recommended. I think that I have seen benefit follow the application of the actual cautery, but it is a remedy that can seldom be had recourse to in practice. It was formerly much and advantageously employed in the Edinburgh Infirmary.

Under whatever form of rheumatism the patient suffer, he should be thoroughly clad in flannel, and, while taking a nutritious diet, he should avoid malt liquors in any shape. Claret I believe to be the best wine for rheumatic subjects. I do not allude to the treatment by mineral baths and waters, as they can only be adopted by the wealthy.

4. *Struma*. Examples of almost every phase of this frightfully common affection has been presented during the two years, and the worst cases that have obtained, have been among the out-patients living in the country. This circumstance may in part be attributable to the greater frequency of intermarriages among blood relations, which is a very common practice among our agricultural poor; and in part also, to the insufficient and innutritious food to which the labourer and his family are often limited; and as a third cause, I would mention the crowded and ill-ventilated bedrooms, and the consequently impure air which, during the long hours of the night, they are doomed to breathe. In the treatment of struma generally, the correction of the circumstances just alluded to, will be of the first consideration, for how many cases of phthisis can be traced back to a strumous dyspepsia, engendered by insufficient ventilation and improper food.

The poor themselves, as is well known, are unhappy very averse to admitting air at night into their overcrowded bedrooms; and even those in a class above them, are too ready to exclude the amount of air which is really necessary to a healthy assimilation. In reference to medicines, the first endeavour should be to correct the disordered condition of the *primæ viæ*, and for this purpose the alkalies with the chlorate of potash, and perhaps, the hypophosphites, will be the best remedies. Afterwards, as a tonic, no remedy will answer better than quinine, to which, if necessary, may be added steel, and the iodide of potassium with cod-liver oil.

A difference of opinion still exists in reference to the management of strumous abscesses in the neck.

Many are in favour of early lancing; my own preference leans to allowing them, as a rule, to break spontaneously under the influence of iodine paint or poultices. After the abscesses have broken and been sufficiently poulticed, the ointment of the iodide of lead will be found an excellent application.

Strumous enlargement of the tonsils is another very troublesome form of strumous constitutional disturbance. As a local application, I generally direct a solution of the nitrate of silver to be painted on the part once daily (a scruple to the ounce); but by many the tincture of iodine applied in the same manner is preferred.

Strumous otitis yields best to blistering behind the ear, correcting the digestive organs, and then giving cod-liver oil and quinine, with calomel and rhubarb twice a week as an alternative. I need scarcely add that the patient should be warmly clad in flannel. Anything indeed that can promote the formation of healthy blood, and prevent or improve depraved nutrition, must be sedulously recommended.

5. *Bronchocoele.* Enlargement of the thyroid gland is an affection of very common occurrence among our out-patients; and it has not departed from the general rule of having presented much more frequently in the female than in the male. As internal medicines, I have generally given large doses of the liquor potassæ with the chlorate of potash, in doses of from five to ten grains. As an outward application, the iodine paint or the compound iodine ointment have been the preparations used.

6. *Purpura.* We have had a few cases of the simpler form of this affection. Although defined by Willan as a skin-disease, purpura is essentially a blood-disorder, in which, under a peculiar condition of system, the blood-corpuscles become disintegrated and diffused. The cases referred to appeared to depend upon passive congestion of the liver in the first instance, which in its turn produced exhausted nerve-tone, and malnutrition, with the purpuric spots.

In the treatment, after regulating the diet, which should be light, but mixed and nutritious, the liver should be thoroughly emptied either by repeated doses of senna with sulphate of magnesia, or by castor-oil. After this, the mineral acids or the tincture of the sesquichloride of iron, with or without quinine, will be the best remedies. In the low form of chronic purpura, with slow, draining, internal hæmorrhage, the oil of turpentine or the ammonio-sulphate of iron will often act beneficially.

7. *Hæmorrhoids.* The examples of this affection, included as medical cases, have been simply external or internal piles, but not sufficiently chronic or severe to require surgical treatment. I have always regarded this often painful malady as one of defective nerve-tone, and depending chiefly upon congestion of the portal circulation. With this view, while giving every night at bedtime a scruple each of magnesia and precipitated sulphur, I have always prescribed with the best effect, at the same time, an alkaline mixture, with full doses of aromatic spirit of ammonia and chloric ether. Cod-liver oil is also a medicine of much value in hæmorrhoidal disease.

CONCLUDING OBSERVATIONS.

I have now completed the running commentary upon the chief class of cases which have come under my notice as out-patients in the last two years. That medicine, as a science, is steadily advancing is unquestioned, and its chief progress is founded upon an increasing knowledge of minute physiology and pathology.

Disease is now not recognised as it was formerly, as being a something *per se*, a distinct and separate

entity, and differing altogether from the normal condition; but it is now regarded simply as a perversion of the natural and physiological phenomena, which are uninterruptedly taking place during health, but which, under the influence of various external and internal exciting causes, so affect the normal vital processes, as to constitute malnutrition or disease. The subject of perverted nutrition is largely occupying the attention of physiological and pathological inquirers, and the investigation of the influence which nerve-nutrition or its opposite exert upon the causation of disease, is full of practical interest and importance.

It is now generally admitted, that the tendency of most diseases, when unaided by treatment, is towards recovery, and that the influence of drugs is more correctly shewn in guiding to a termination in health, rather than by attempting abruptly to cut short the progress of the malady.

In order, however, to reduce our knowledge of the effects of medicines upon disease to as much exactitude as possible, it is, as I remarked at the commencement of these papers, very important that the results of individual remedies be faithfully and carefully collected and reported. For this purpose, nothing but "combined medical observation" can avail, and in no way can this be better effected than by inducing the individual members of our large Association to give a brief record of the results of their own treatment, and to test and report on the treatment of others.

Whatever course be adopted for the obtaining this result, whether by a reissue of schedules, or by any other method of inquiry, I would merely suggest the importance of condensing and simplifying the questions as much as possible, so that answers from the fully engaged practitioner may not be wanting.

NOTES ON HERNIA.

By JOHN THOMPSON, M.D., F.R.C.S., Bideford.

[Continued from p. 221.]

WHEN reduction of a strangulated hernia by the taxis and its aids is found impracticable, nothing remains but the operation by incision. It happens but too frequently that the patient either objects to this, or requests delay and further consultation. The difficulty of managing him may thus be more trying than the treatment of his disease. Keeping this in mind, it is generally wise at the outset to say that, in case the efforts with the hand, etc., do not succeed, it will be necessary to use the knife. A timid person often becomes reconciled to an operation when time is allowed him to make up his mind; and the more early this is done, the better the prospects of the case.

In provincial practice the results of operations are so generally known, and so long remembered, especially when they are unfavourable, that it is matter of importance, for the welfare of future sufferers, that an established operation should not suffer in reputation, which it must do, if performed only as a last resort, when pain and agony compel compliance. It is most notable how strong is the logic of facts on the mind of a sufferer; let him know that others afflicted as he is, have successfully passed through the operation, and your point is almost gained; but, on the other hand, sinister information of unsuccessful cases equally disposes in the opposite direction. Feeling that next in importance to the performance of the operation is the question of time, I have dwelt the more on these matters, which, though simple, may be of considerable consequence.

In operating, a surgeon experiences how much more easily the scalpel cuts a living than a dead tissue, and practice thus makes a man careful how he divides integuments tensely extended over a convex elastic hernial tumour. From not exercising a sufficiently delicate appreciation of the force to be applied, I have found my first incision to be more penetrating than I had expected, and I have known the same occur to others. Division of the integuments by transfixion is, I believe, the preferable practice, being more safe and less painful.

A firm director is next passed under the fasciæ, layer after layer, a friend guarding its distal extremity in each instance with his thumb-nail, the operator then adroitly runs the scalpel along the director with its back in the groove, and the tissues are easily and safely divided. Cutting against the director is a rather clumsy procedure, and moreover does the edge of the scalpel no good.

Where the patient is very fat, it is a point of importance to have the integuments along the incision kept clear of the knife; and here bent spatulæ are specially useful, but if not to hand, as may happen in country practice, bent knitting needles are easily extemporised, and answer almost equally well. When the sac is reached, if it be determined to open it, pinching up the bag and rubbing the layers as a powder is dealt with between the finger and thumb, enables one to discriminate between sac and intestine; a snip is made in the former, the director passed in, and a sufficient incision made in it to allow the easy introduction of the finger. The stricture is next felt for, and divided by a hernia-knife or a bistoury, either guided on the finger or along the groove of the director, and kept well up against the upper border of the ring. A very slight incision is sufficient, and a gentle to and fro movement with the knife is a good way of effecting it. A free division is unnecessary; it adds to risk, and probably may render the future protrusion more facile and bulky.

When the stricture is thought to be divided, gently pull down the intestine a little way, and press it with the finger and thumb; if it be relieved from the constriction, some of its contents will pass up, and the coats become flaccid; then holding the sac by the finger and thumb of one hand, and delicately pressing up the intestine with the finger and thumb of the other, it readily enters the abdomen; the forefinger may be passed along the canal after it, to ascertain that reduction is normal and complete.

Every step is more easily performed where the operation is undertaken early in the disease, than when by delay and oft repeated handling, congestion and inflammation have been set up.

Nearly twenty years ago, I was sent for at night to attend a respectable middle-aged man, afflicted with strangulated serotal hernia. The taxis failed; bleeding and the warm bath were added, but without avail. I then injected large quantities of cold water *per anum*, and applied the same to the scrotum, but reduction was still impracticable. In the morning I obtained the assistance of two professional friends, and again a course of manipulation was employed, but nevertheless the strangulation was unrelieved.

I then proceeded to operate, and soon reached the sac, which was opened. Inside this there were felt some constricting bands from the tissue without, and I passed up a bistoury guided by a director, and with some decision divided them. The sudden liberation of the compressed intestine caused it to rebound, and it thus overlapped the edge of the knife and received a small wound, which penetrated the coats and allowed some contained fluid, which proved to be the water from the injection, to spirt out. After the gut was thus emptied, a fine suture was passed around the margin

of the puncture, which was only of about the size of a crow-quill, by one of my friends, and the intestine gently returned into the abdomen. The usual mode of treating the wound with sutures and plaster was employed, and the patient became relieved from his suffering.

No untoward symptoms followed for several days, when considerable inflammation and swelling of the scrotum took place; and the patient informed me that he felt as if the wind in his bowels "worked" to the part where he had been cut. I suspected that there was an escape of fæces and gas from the wound in the intestine, which caused the distension and attendant inflammation. After no long time, a discharge from the scrotum confirmed my suspicion; but, excepting this, the patient's state was very satisfactory, the functions of the system being normally performed.

It struck me that so small a wound could only produce a sinus, and that, in connexion with this, the intestine would be sure to contract adhesion near the mouth of the ring, after a little time had elapsed, when, by judiciously applied compression, I might obliterate the inguinal canal, which would be in an inflamed condition and apt for adhesion. Accordingly, after a sufficient interval, I applied a good compress, and supported it well by a figure-of-8 bandage. This completely answered my expectation; the passage became closed, and, by consequence, the discharge ceased, and the patient was cured.

In a short time, the man was again at his occupation; and he never suffered anything to indicate that the accident had done him lasting injury. I have recently examined his groins, and found a large inguinal hernia of the opposite side, and a smaller one on the side where he was incised; that the latter is relatively small, arises from the altered conditions effected by the adhesions consequent on the operation.

The man is now the subject of heart-disease, and holds his life precariously. Should he die before me, I shall try to ascertain, by a *post mortem* examination, the precise condition of the maimed gut and contiguous canal. I cannot omit to mention, in connection with this case, that my friends honourably kept the accident a secret; and, as the result of the operation was so favourable, I have ever since been much esteemed by the patient.

The operation of dividing the stricture without opening the sac has been so favourably reported on that, where the case is suitable, as happens very generally in femoral herniæ, it becomes a duty to adopt it. The cutting down to the sac is, of course, performed just as in the old operation, though the external incision need not be quite so extensive. On arriving at the sac, one surgeon may use his finger as a guide for the bistoury between this and the fascia, another a director; but it is worth mention, that either will readily pass over the falciform process and into the overlying tissue, unless care be used to see that the cribriform fascia over the sac is properly divided. I have seen this so tightly laid on the hernia that it seemed a part of the sac, and the director was tilted by it over the falciform process, where, of course, division of the fascia had nothing to do with relieving the stricture. When these matters are properly managed, there is no difficulty in passing the finger or a director up under the stricture, and making it the pioneer and guard of the knife.

After the stricture is divided, the intestine is readily returned, if the hernia be recent; but, in old cases, where the sac has become, as I have seen, prodigiously thickened about its neck, there may be considerable difficulty in pressing up the intestine. It

has happened that, in attempting to do this, both it and the sac have been returned together into the abdomen, an accident much to be regretted; but still it is not necessarily of such serious import as the opponents of this operation would have us believe; for, as the main cause of strangulation is in the unyielding fascia which has been divided, and not in the partially elastic sac, the latter, though holding the intestine as the finger of a glove does the finger, may yet permit circulation in the vessels and passage through the intestine.

I have never seen an unopened sac returned into the abdomen along with the intestine; but I have known the return of a partially opened sac, the neck being entire and closely embracing the gut, and yet no untoward symptoms followed; nay, I believe the patient was, in one respect, benefited; for, as inflammation had been already set up, the less the sac was incised the better, provided strangulation was relieved.

To avoid the possibility of returning the sac, I have adopted the plan of separating the fundus from the fascia to a small extent; then, on applying the finger and thumb of the left hand, the intestine is felt within, and probably separated from it by a little contained fluid. Holding the sac at its extremity with this hand, the intestine is to be pressed up with the finger and thumb of the other; so that, practically, extension and counter-extension are exerted, the one part being pressed up and the other held down at the same time; thus, I have found reduction easily effected. Of course, much of the ease with which we obtain our end, must depend on the state of the sac; but yet it is pretty evident that the plan named must be greatly better than that which permits the pressure to act on both sac and intestine at once and in the same direction. In this, as in other surgical practice, experience is the test; a trial of this proposal will, I am convinced, insure its adoption.

It is striking to notice how little comparative shock is given to the system by this form of operation, and the quickness with which recovery is effected. I operated on two cases of hernia in May of last year; in the one I opened the sac, and in the other I divided the stricture without opening. In the latter, the patient was pretty well at the end of a week, and about his farm business in a fortnight; but the former took eight weeks to recover. Much stress cannot be laid on impressions produced from small experience; but yet I cannot help feeling strongly persuaded of the superiority of this operation, which, I suppose, may, in its main points, be termed that of Mr. Gay.

[To be continued.]

ROYAL MINT. Dr. Stenhouse, F.R.S., has been appointed by the Master of the Mint non-resident assayer to the Royal Mint, in the place of Dr. Hofmann resigned. (*Chem. News.*)

THE PHYSICIANS OF CHAMBERSBURG. The sad experiences of the citizens of Chambersburg, during the past summer, when subjected to the tender mercies of a portion of the rebel army, who wantonly sacked and destroyed that beautiful village by fire, is yet fresh in the memory of our readers. It came incidentally to our knowledge lately, that every one of the physicians resident in the place at that time, viz: Drs. A. H. Senseney, J. Montgomery, J. L. Suesserott, S. S. Huber, Samuel H. Boyles, J. C. Richards, and Langheim, lost their all, including household goods, office furniture, surgical instruments, libraries—everything. Some of them barely escaped with their lives. (*Philadelphia Medical Reporter.*)

The Medical Council.

REPORT OF PROCEEDINGS, APRIL 1865.

THURSDAY, APRIL 6TH.

G. BURROWS, M.D., President, in the Chair.

The Army and Navy Medical Examinations. The following communications from the Directors-General of the Army and Navy Medical Departments relative to the Examination of Candidates for Medical Commissions, were read.

Army Medical Department, June 20th, 1864.

SIR,—In acknowledging the receipt of your letter, dated 27th ultimo, conveying the request of the General Council of Medical Registration to be furnished annually with information on the following points; viz.:

“(a) The total number of candidates for medical commissions who have presented themselves for examination;

“(b) The number of those who passed, and of those who did not pass, the examinations of the Board, distinguishing the number of successful and unsuccessful candidates under the respective heads of the several licensing bodies mentioned in Schedule (A) to the Medical Act, and specifying their qualifications, medical and surgical, and whether they had failed in medicine or surgery;

“(c) The general nature and scope of the examination conducted by the Board, together with a list of the questions proposed by the Examiners”;

I have the honour to inform you, in reply, that Lord De Grey has been pleased to accede to the wish of the General Council, and I shall be obliged by your signifying from what date the information is required.

I have the honour to be, sir,

Your most obedient humble servant,

(Signed) J. B. GIBSON, *Director-General.*

F. Hawkins, Esq., Registrar, General Council of Medical Education, 32, Soho Square, W.

Army Medical Department, Feb. 23rd, 1865.

SIR,—With reference to your letters dated 27th May and 24th June last, the former communicating a resolution passed at a late session of the General Council of Medical Education, that certain information should be furnished by this Department, annually, in regard to the number of candidates who have presented themselves for examination, and specifying certain points on which the Council request to be informed, I have the honour to forward a statement on the subject, with a list of the questions proposed by the Examiners; and to observe, in regard to the general nature and scope of the examination, that the enclosed copy of the regulations for the admission of candidates into the Medical Department of Her Majesty's Army (section 5, page 8) will probably supply the information which the Council are desirous to obtain.

I have the honour to be, sir,

Your most obedient humble servant,

(Signed) J. B. GIBSON, *Director-General.*

Fras. Hawkins, Esq., Registrar, General Council of Medical Education, 32, Soho Square.

[A list of the subjects of examination was appended to this letter.]

Statement of the Degrees, Diplomas, and Licences, of the Candidates for Commissions in the Medical Department of the Army, who, during the year 1864, have presented themselves for examination, showing the number that passed and did not pass; also distinguishing the Qualifications, both Medical and Surgical, under the heads of the several Licensing Bodies, and specifying whether the candidates failed in Medicine or Surgery.

Admiralty, W.C., 13th March, 1865.

SIR,—With reference to your letter of the 27th of May last, I have the honour to forward, for the information of the General Council of Medical Education and Registration of the United Kingdom, a Report from the Board of Examiners on the examinations of candidates for Medical Commissions in the Royal Navy during the year 1864.

I have the honour to be sir,

Your very humble servant,

(Signed) A. BRYSON, *Director-General*.

Dr. F. Hawkins, Registrar of the General Council of Medical Education and Registration of the United Kingdom, 32, Soho Square.

Admiralty, Somerset House, 6th March, 1865.

SIR,—We have the honour to submit, for the information of the General Council of Medical Education and Registration of the United Kingdom, the following Report on the Examinations of Candidates for Medical Commissions in the Royal Navy during the year 1864. 1. The total number of candidates who presented themselves for examination during the year was forty-nine; of these, twenty-one were rejected, having failed to satisfy us as to their professional knowledge; and one was found to be physically unfit for the service. 2. The accompanying table supplies the information required by the Medical Council with reference to the qualifications of the candidates, and the points on which they were chiefly

deficient. 3. The examination is *viva voce*; but each candidate is furnished with a paper containing a question or questions upon subjects of a professional nature, to which he is expected to reply in writing; and, previous to the oral examination, he is required to translate a paragraph from a Latin author. 4. In its scope, the examination embraces all the ordinary subjects of professional study; viz., Anatomy, Surgery, Practice of Medicine, Midwifery, Materia Medica, Chemistry, and Botany. 5. Being a *viva voce* examination, and the questions being left to the judgment of each individual examiner, it is not possible to furnish a return of those actually proposed; but appended hereto is a list of the subjects on which the candidates have at different times been examined, and which, put in the interrogatory form, gives a fair idea of the general character of the questions. The Council is, doubtless, fully aware that, in such examinations, the same question requires to be put in a variety of forms, to meet the various comprehensions to which they are addressed. 6. We regret to have to report that, in a very large number of cases indeed, the candidates displayed a lamentable ignorance of Latin; some were scarcely able to translate the *Pharmacopœia*, and but few possessed a useful knowledge of the language. From the nature of the excuse most frequently made by them, it appears to us that very many had acquired only a sufficient acquaintance with the language to enable them to pass the preliminary examination of other Boards, and that they had then thrown it aside as altogether useless. 7. We have also to regret that so important a branch of professional education as operative surgery on the dead body should so rarely enter into the curriculum of study of those who come before us; and we desire to express a strong opinion that no surgical diploma should be attainable without satisfactory evidence being produced that the principal operations in surgery had been performed on the dead body under a qualified teacher.

We have the honour to be, sir,

Your very humble servants,

E. HILDITCH, M.D., *Inspector-General*.

J. W. SALMON, *Dep. Inspector-General*.

ALEX. E. MACKAY, M.D., *Dep. Insp.-Gen.*

Dr. Bryson, F.R.S., *Director-General*.

Qualifications, according to Schedule (A), of the different Candidates who were examined for Medical Commissions in the Royal Navy in 1864, with the Results of the Examinations.

[For convenience of printing, the facts contained in the table referred to, are given in the following summary.]

1. Mem. R. Coll. Surg. Eng., and M.D. Univ. Edin. Rejected. Deficient in anatomy, surgery, and practice of medicine.

2. Lic. R. Coll. Surg. Edin., and M.D. Univ. Edin. Passed. Surgery and practice of medicine only fair; otherwise good.

3. Lic. R. Coll. Surg. Irel. Found to be physically unfit.

4. M.D. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed a good examination in all branches.

5. Lic. K. and Q. Coll. Phys. Irel., and Lic. R. Coll. Surg. Irel. Rejected. Ignorant of anatomy.

6. Lic. R. Coll. Surg. Irel. Passed. Anatomy, surgery, and practice of medicine, only fair; other branches good.

7. Mem. R. Coll. Surg. Eng., and M.D. Univ. Edin. Passed a good examination in all branches.

8. Mem. R. Coll. Surg. Eng., Lic. Soc. Apoth. Lond., M.D. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed. Practice of medicine only fair; other branches good.

9. M.B. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed a good examination in all branches.

10. Lic. R. Coll. Surg. Irel., and M.D. Univ. St. Andrews. Passed a good examination in all branches.

11. Lic. R. Coll. Phys. Lond., and Mem. R. Coll. Surg. Eng. Passed. Anatomy and surgery good; practice of medicine and other branches only fair.

12. Lic. K. and Q. Coll. Phys. Irel., and Lic. R. Coll. Surg. Irel. Passed. Anatomy and practice of medicine, and all other branches, except surgery, good; surgery fair only.

13. Lic. R. Coll. Phys. Lond., and Mem. R. Coll. Surg. Eng. Rejected. Utterly ignorant of the Latin language.

14. Lic. K. and Q. Coll. Phys. Irel., and Lic. R. Coll. Surg. Irel. Passed. Anatomy and practice of medicine good; surgery fair only; other branches fair and indifferent.

15. Lic. R. Coll. Phys. Lond., and Mem. R. Coll. Surg. Eng. Passed a good examination in all branches.

16. Mem. R. Coll. Surg. Eng., and M.B. Univ. Durham. Rejected for the third time. Anatomy and surgery bad.

17. Lic. R. Coll. Surg. Irel. Rejected for the second time. Anatomy and surgery bad.

18. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Rejected. Utterly ignorant of the Latin language.

19. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Passed a good examination in all branches.

20. Lic. R. Coll. Surg. Edin., and M.D. Univ. Edin. Passed. Anatomy and surgery good; practice of medicine and other branches only fair.

21. Lic. K. and Q. Coll. Phys. Irel., and Lic. R. Coll. Surg. Irel. Rejected at the first examination. Anatomy only fair; surgery very bad. Passed the second examination. Surgery and other branches were fair.

22. Lic. R. Coll. Phys. Edin., and Lic. R. Coll. Surg. Edin. Rejected. Anatomy and surgery indifferent.

23. Lic. R. Coll. Surg. Irel. Rejected. Ignorant of Latin and anatomy.

24. Lic. R. Coll. Surg. Irel. Rejected. Utterly ignorant of the Latin language.

25. Lic. R. Coll. Phys. Edin., and Lic. R. Coll. Surg. Edin. Passed. Anatomy good; surgery only fair; practice of medicine indifferent; other branches fair.

26. Lic. R. Coll. Surg. Irel. Passed. Anatomy, surgery, and practice of medicine good; other branches fair.

27. M.D. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed. Anatomy and surgery only fair; practice of medicine good; other branches fair.

28. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Rejected. Anatomy bad; surgery and practice of medicine indifferent.

29. Lic. R. Coll. Phys. Edin., and Lic. R. Coll. Surg. Irel. Passed. Anatomy good; surgery and practice of medicine fair; other branches fair.

30. Lic. R. Coll. Phys. Edin., and Lic. R. Coll. Surg. Edin. Rejected. Anatomy indifferent; surgery bad.

31. Lic. R. Coll. Phys. Edin., and Lic. Fac. Phys. and Surg. Glasg. Rejected. Utterly ignorant of the Latin language.

32. Lic. R. Coll. Surg. Edin., and M.D. Queen's Univ. Irel. Passed. Anatomy indifferent; surgery, practice of medicine, and other branches, only fair.

33. Lic. R. Coll. Phys. Edin., Lic. R. Coll. Surg. Edin., and Lic. Apoth. Hall, Dublin. Rejected. Anatomy only fair; surgery bad; practice of medicine indifferent.

34. Lic. R. Coll. Phys. Edin., and Lic. R. Coll. Surg. Edin. Passed. Anatomy and practice of medicine good; surgery only fair; other branches fair.

35. Lic. Fac. Phys. and Surg. Glasg. Passed.

Anatomy good; surgery fair; practice of medicine indifferent; other branches fair.

36. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Rejected at the first examination. Anatomy and surgery bad. Passed in 1865, second examination. Passed a good examination in all branches.

37. M.B. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed. Anatomy, surgery, and practice of medicine good; other branches fair.

38. Mem. R. Coll. Surg. Eng. Rejected. Latin and anatomy bad.

39. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Rejected. Anatomy indifferent; surgery only fair; other branches and Latin bad.

40. Lic. R. Coll. Surg. Edin., and M.D. Univ. Edin. Rejected. Anatomy indifferent; surgery bad; and other branches bad.

41. Mem. R. Coll. Surg. Eng., and M.D. Univ. St. Andrews. Passed second examination. Anatomy, surgery, materia medica, and botany good; other branches fair.

42. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Rejected. Latin, anatomy, and surgery bad.

43. Mem. R. Coll. Surg. Eng., and M.D. Univ. Edin. Passed a good examination in all branches.

44. M.B. Univ. Aberd., and Mast. Surg. Univ. Aberd. Passed. Anatomy and practice of medicine good; surgery only fair; other branches fair.

45. Lic. R. Coll. Surg. Edin. Rejected. Latin and anatomy and surgery indifferent; materia medica bad.

46. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Passed a good examination in all branches.

47. Mem. R. Coll. Surg. Eng., and Lic. Soc. Apoth. Lond. Passed a good examination in all branches, excepting practice of medicine, which was only fair; Latin indifferent.

48. Lic. R. Coll. Surg. Irel., and Lic. Apoth. Hall, Dublin. Rejected. Utterly ignorant of the Latin language.

NOTE. Several of the candidates possessed qualifications which are not included in Schedule (A).

Dr. ANDREW WOOD moved—

“That the communications from the Directors-General of the Army and Navy Medical Departments, relative to the examinations of candidates for medical commissions, be received and entered on the minutes.”

He considered that great credit was due to Dr. Apjohn for having last session proposed the application to the Directors-General for the returns. Every examining board would derive benefit from their publication.

Dr. PARKES seconded the motion, which was unanimously carried.

Dr. APJOHN moved, Dr. PAGET seconded, and it was resolved—

“That the thanks of the Medical Council be given to the Directors-General of the Army and Navy Medical Boards, for the valuable returns which they have made of the results of the examinations held by them in 1864 of candidates for medical appointments in their respective services; and that a request be made to the Director-General of the Army Medical Department that he will be pleased to sanction, for the future, similar returns for Her Majesty's Indian Medical Service.”

Report on Communications relative to Amendments of the Medical Acts. Dr. EMBLETON presented the following

REPORT.

Your Committee have read and considered the letters, etc., referred to them, and find that some, having respect to Sections xxxvi, xl, xli, xlii, and

XLVII of the Medical Act, on which the Council has already come to a decision, do not appear to require to be brought before the Council.

Others, however, referring to other matters, require consideration, and are now brought before the Council, viz.:

1. A letter from J. F. Milner, Esq., Hereford, dated December 2nd, 1864, praying for protection of registered medical practitioners against the practice of medicine by chemists and druggists, and against the holding of club appointments by the same.

2. A letter from E. E. Tucker, Esq., of Abersychan, dated February 3rd, 1865, complaining of the practice of surgery by a gentleman in his neighbourhood, whose only qualification is that of the Society of Apothecaries of London.

3. A letter from Dr. Styrap, Shrewsbury, dated March 3rd, 1864, asking that increased powers be given to magistrates with respect to offences against the Medical Act, and that the penalty on second conviction be increased.

4. The following memorial, dated April 3rd, 1865, from twenty-eight Licentiates in Dental Surgery of the R.C.S. England, asking that, under the proposed Medical Act, they be allowed to register as Licentiates in Dental Surgery.

D. EMBLETON, *Chairman.*

To the General Council of Medical Education and Registration of the United Kingdom.

We, the undersigned, Licentiates in Dental Surgery of the Royal College of Surgeons in England—a (degree founded by the College on Section XLVIII of the present Medical Act)—although entitled to register under that Act, in virtue of our other professional qualifications, considering it to be desirable, and believing it to be only just, that those persons who have taken this degree should be allowed the privilege of registering as “Licentiates in Dental Surgery,” under the proposed amended Medical Act, beg respectfully to bring this, our view of the subject, under the consideration of your Honourable Board.

We are aware that the following objections have been raised to this privilege being allowed to the possessors of this degree:—

First. That, if the privilege were granted to persons who have taken this degree only, they would, under Clause xxxiv of the present Medical Act, be considered in law as “duly qualified medical practitioners,” and might, if so disposed, practise legally any, or all branches of the medical profession without having received a full medical education, and thereby interfere with the interests of the fully qualified medical man.

Second. That to grant this privilege to them would be to infringe upon and injure the existing rights of those persons at present practising dental surgery who do not possess this degree, by giving to the new Act a retrospective character; and

Third. That it is open to those persons practising dental surgery, who desire to possess the privilege of registering under any Medical Act, to take the degree of “Member” of the College of Surgeons as well as that of “Licentiate in Dental Surgery,” and to register under the former title.

To the first of these objections we respectfully submit, that the very slight additions we have suggested to the wording of Clauses xxxi and xxxiv of the present Medical Act, would, if adopted, make it clear beyond the possibility of a doubt, that the possessors of this degree only, if registered as “Licentiates in Dental Surgery,” could not legally practise any other branch of medicine or surgery, and therefore that the incorporation of these, or similar words, into any

amended Medical Act, would fully meet and do away with this objection.

To the second objection we also respectfully submit, that the few words proposed to be added to Clause LV of the present Medical Act would, if adopted and incorporated with such amended Medical Act, completely protect all the existing rights of those persons at present practising dental surgery who do not possess this degree, as also the respective rights of those at present preparing to practise dental surgery who may not have it in their power to take this degree, and so meet and do away with this objection.

And to the third objection we respectfully submit:

First. That the argument on which it rests is founded upon an imperfect knowledge of the amount of “special duty” required to form the duly qualified dental surgeon, as we think will be apparent to your Honourable Board by a reference to the accompanying curriculum of education required by the College of Surgeons for the degree of Licentiate in Dental Surgery;—

Next. That to expect the full course of education required for the “Membership” of the College to be added by the dental surgeon to the curriculum required for his special diploma, in order to give him the power of registering under such Act, would be to exact a more extensive and more expensive professional education, both in respect to time and money, from the dental than from the general surgeon—a requirement which we most respectfully submit would be both unnecessary and unjust; and,

Lastly. That to be registered as a “Fellow” or “Member” of the College only, does not *in itself* afford any proof that persons so registered are duly qualified to practise the speciality of dental surgery, as we think will also be apparent to your Honourable Board after referring to the curriculum above named.

Entertaining these views, we think it right to bring them under the attention of your Honourable Board, and we pray that you will take them into your favourable consideration.

Thomas Bell, F.R.C.S., L.D.S., F.R.S., John Tomes, F.R.S., L.D.S., M.R.C.S., Samuel Cartwright, F.R.C.S., L.D.S. (members of the Board of Examiners in Dental Surgery of the Royal College of Surgeons of England); Arnold Rogers, F.R.C.S., L.D.S., late member of the above Board; W. A. Harrison, F.R.C.S., L.D.S., C. A. Ibbetson, F.R.C.S., L.D.S., William A. Cattlin, F.R.C.S., L.D.S., A. G. Canton, M.R.C.S., L.D.S.; Thomas Rogers, M.R.C.S., L.D.S., President of the Odontological Society of Great Britain; H. J. Barrett, M.R.C.S., L.D.S., S. J. A. Salter, M.B., M.R.C.S., L.D.S., F.R.S., Henry Rogers, M.R.C.S., L.D.S., Alfred Barrow Jones, M.R.C.S., L.D.S., Edwin Sercombe, M.R.C.S., L.D.S., John W. Elliott, M.R.S.C., L.D.S., Nathaniel Stevenson, M.R.C.S., L.D.S., H. Howard Hayward, M.R.C.S., L.D.S., Joseph Rogers, M.R.C.S., L.D.S., William A. Allingham, M.R.C.S., L.D.S., Charles Vasey, L.F.P.S., L.D.S., John Thomas Henry West, M.R.C.S., L.D.S., George Gregson, M.R.C.S.E., L.D.S., E. H. G. King, M.R.C.S., L.D.S., Thomas C. White, M.R.C.S., L.D.S., Charles James Fox, M.R.C.S., L.D.S.

Dr. EMBLETON moved, Dr. FLEMING seconded, and it was resolved—

“That the Report of the Committee on Communications relative to Amendments of the Medical Acts be received and printed, together with the four documents particularised, under the direction of the Business Committee.”

Visitation of Examinations. Dr. ANDREW WOOD moved, Dr. FLEMING seconded, and it was unanimously resolved—

“That the Council resolve itself into a Committee of Education, and that the President be requested to take the chair.”

Dr. PARKES moved the following resolution.

“That a Committee of three be appointed, one member from each division of the kingdom, to be called the Committee on Education.

“That the powers and duties of this Committee be—

“1. To prepare a definite statement of the systems of examination of the different licensing bodies, as stated in the documents already sent in to the Council, so that the agreements and differences of the several systems may be brought into one view. For this purpose the Committee shall be enabled to seek further information, if necessary, from the different licensing bodies, through the Registrar of the Council.

“2. To arrange a plan by means of which, without actual visitation, the different examinations may be continually supervised, and to submit this to the several Branch Councils, after which the Committee be empowered to act upon it.

“3. To arrange a plan for the visitation of examinations, when that is necessary, either by the agency of members of the Council, or of other members of the profession selected especially for this duty, and to submit this plan to the Branch Council, and subsequently, when it has been approved of, to act upon it.”

He said that the communications which the Council had received from the various licensing bodies showed a general wish on the part of these bodies to comply with the rules of the Council. But, however valuable the regulations of the Council might be, a careful supervision of examinations was necessary in order to produce any good result. It would be a dereliction of duty on the part of the Council to neglect such supervision. He proposed a small Committee, because the matter would be thus better managed than by the whole Council or by the Executive Committee; and he would suggest that the Committee should be formed of the members nominated by the Crown. The duty of the Committee should be to consider all the documents sent in on the subject of education, and to frame a scheme thereon. He considered this necessary because, although at present the rights of practice were uniform, the Council did not know to what extent there was uniformity in the qualifications required by the licensing bodies. There should be a regular supervision of examinations, but it would be impossible always to be present. Much information, however, might be gained from a consideration of the written answers of the best and the worst candidates. The personal visitation of examinations should be occasional; so that the examinations of all the licensing bodies might be inspected in the course of three or four years. He could not consider that the visitation of examinations would be at all derogatory to the examiners. He did not desire to press his motion in the precise form in which it was put, but was merely desirous of organising some plan for the supervision of examinations.

Dr. PAGET seconded the motion.

Mr. HARGRAVE remarked that the examinations of the College of Surgeons in Ireland were public, being open to all the Fellows of the College.

Dr. CORRIGAN did not see how Dr. Parkes's plan could be carried out. The labour thrown on the three members of the Committee would be frightful; for it would be impossible to select for consideration some of the examination-papers without reading all.

Last year, about two thousand candidates passed; and he calculated that the reading of their papers would require forty thousand hours. He would not like to be on such a Committee. As to supervision, it had been said that the object was not always to see that the examiners perform their duty properly; but if not, of what use was the supervision? The proper remedy, both against undue severity and against laxity, would be to throw open the examinations to all the members of the body. In Trinity College, all the students and the public were admitted; and the plan worked well.

Dr. STOKES said that there ought to be some supervision of the preliminary examinations. He could not see how the presence of members of Council at an examination could be considered derogatory to the examiners. He feared, however, that the plan proposed by Dr. Parkes would be difficult to carry out, and slow of operation.

Mr. SYME considered that the Medical Council had hitherto failed in its duty as regarded the visitation of examinations.

Dr. QUAIN suggested that the Council should first decide whether or not there should be supervision of examinations. The subject might be taken up in its place in the discussion on medical education,

Dr. CHRISTISON considered that it was important to come to a decision on the subject of supervising examinations; but he did not see how the plan proposed by Dr. Parkes could be carried out.

Dr. AQUILLA SMITH referred to the returns from the Army and Navy Medical Departments, as showing the necessity for visitation of examinations, preliminary as well as professional. He had observed that the standard of knowledge of Latin was becoming lower among persons entering the medical profession; and some even did not know the English language.

Mr. SYME moved as an amendment—

“That each of the Branch Councils, or such of their members as may be deputed by such Councils, shall, from time to time, visit the examinations, preliminary as well as professional, conducted by the qualifying bodies in their respective divisions of the United Kingdom, and report the results of their observations to the General Council.”

Dr. ANDREW WOOD seconded the amendment. He believed that the visitation of examinations would be one of the most wholesome stimuli to the examining boards. These bodies had no right to object to such visitation; and he believed they would not object—indeed, the Edinburgh Colleges and the Glasgow Faculty had expressed opinions in favour of supervision. There were several ways in which supervision might be carried out. In the first place, the examinations, it had been said, might be public; but he would ask whether those boards which followed the plan of public examinations sent forth the best qualified men. In Scotland, publicity would not work well; because in that country even the best qualified students would be liable to experience that unpleasant sensation known as “funk”, if examined in the presence of their fellow-students. Again, if the examinations were thrown open, it would not be members of the profession who would attend them, but students, for the purpose of finding what questions they were likely to be asked in their examinations. The grinders also would attend most diligently. There were still two other plans; either that the members of the Council should supervise the examinations, or that they should depute the duty to others. To the employment of experts there were these objections; that it would be attended with expense, and that none could be employed as visitors but men of the highest professional position, many of

whom were themselves examiners. The plan proposed by Mr. Syme should be tried. It might perhaps fail; but in any case the Council was bound to undertake the visitation of examinations.

Dr. CORRIGAN spoke in favour of public examinations. As to the presence of students and young practitioners, these would be the very men who would produce a sound public opinion. He considered Mr. Syme's proposal quite impracticable; it could not be carried out in Dublin.

Dr. PARKES, by permission of the Council, withdrew his motion; so that Mr. Syme's amendment became the substantive motion.

Dr. ACLAND thought that the visitation of examinations should not be delegated to each Branch Council separately. He would prefer action on the part of the entire Council.

Dr. PAGET remarked that the Council had the power of visiting examinations, but had no power to enforce publicity. He considered there was some objection in the separate working of the Branch Councils in the manner proposed. He moved as an amendment—

"That the Branch Councils be instructed severally to organise a set of *trial visitations*, on a scale which may enable them to report upon the success of such visitations, the conditions for their efficiency, and the requisite means for rendering them adequately extensive."

Dr. QUAIN seconded the amendment.

Dr. SHARPEY preferred visitation to emanate from the central authority rather than from the Branch Councils. It was not necessary that the visitations should be made otherwise than at irregular periods; nor would it be necessary to examine more than a few of the papers, such as those of the lowest who had passed and of the highest among the rejected. As to the objection that visitation would be invidious, he would observe that in the early days of the University of London the examinations of that body were attended by the censors of the Royal College of Physicians; and he, as an examiner, had felt no humiliation from their presence. There was a difficulty in carrying out visitation, from want of funds; but he thought this might be overcome by the deficiency being made up by a vote of Parliament.

Dr. STOKER said that the returns of the Army Director-General shewed the necessity of visitation. Dr. Sharpey's plan was good, but would not be practicable without an amended Act.

After some remarks from Dr. STOKES and Dr. CORRIGAN, the votes were taken on Dr. Paget's amendment, when there appeared: for, 4; against, 10. The amendment was therefore lost. Mr. Syme's motion was then put to the vote, and carried *nem. con.*

The Council then resumed.

Report of the Pharmacopœia Committee. Dr. QUAIN brought up the following

REPORT.

The *Pharmacopœia* Committee beg to report that, after much careful consideration, they requested Mr. Warrington, of the Apothecaries' Hall, and Dr. Redwood, of the Pharmaceutical Society, to undertake the preparation of the next edition of the *Pharmacopœia*, under the supervision of the Committee. The gentlemen named accepted the duty, and they are engaged actively in its performance. The Committee, in the first instance, prepared an outline of the subjects which seemed to them to require revision; and these subjects are made the basis of careful inquiries by Messrs. Warrington and Redwood, who have submitted, and will continue to submit, their reports thereon, together with such suggestions as they think proper to make for the consideration and decision of

the Committee. The Committee have also received valuable assistance from Dr. Farre, appointed by the English Branch Council, and from Dr. Moore, appointed by the Irish Branch Council, to report on the improvement in the progress of pharmacy; and they hope that the services of these gentleman, as well as of Dr. Christison, may be continued.

Taking the first edition of the *Pharmacopœia* as a basis, compiled, as it has been, with great labour and expense, the Committee hope that, without making any very extensive or fundamental changes, the next edition will be found acceptable to the profession.

GEORGE BURROWS, M.D., *Chairman.*

April 3rd, 1865.

On the motion of Dr. QUAIN, seconded by Dr. ANDREW WOOD, the report was received and ordered to be entered on the minutes.

FRIDAY, APRIL 7TH.

G. BURROWS, M.D., President, in the Chair.

The minutes of the last meeting were read and confirmed.

Practice of Chemists and Druggists. Dr. ACLAND moved—

"That, with reference to the letter of Mr. Milner of Hereford, a Committee be appointed, to consider and report whether the Medical Council is charged under the Medical Act with any duty in relation to medical and surgical practice by chemists and druggists; and whether any, and if so what, changes in the Medical Act are desirable with regard to it; and to consider and report on the two Bills relating to pharmacy now before Parliament."

He said that it had been thought expedient that the question of the regulation of the practice of pharmacy should be considered by the Council. The present Medical Act gave the Council no more power over the chemists and druggists than over other unqualified practitioners of medicine; but it was time to consider whether the Council ought not to have such power. He did not know how matters stood in Scotland and Ireland; but in England the druggists were becoming, without having received medical education, rivals to the medical practitioners. Many members of Council were not aware of the extent to which medical practice was carried on by druggists in the country; but he knew that druggists often had large practices at home, and also visited patients. Many registered practitioners, also, found it expedient to assume the outward appearance of chemists and druggists, in order to gain practice. He referred also to the use by druggists of the prescriptions of registered practitioners.

Dr. PARKES seconded the motion. The subject was one which the Council ought to take into their most serious consideration. In the Bill brought into Parliament by Sir J. Shelley (that of the United Society of Chemists and Druggists) there was no saving clause against interfering with medical practice; and the clause inserted for the purpose in the other bill (that of the Pharmaceutical Society) was not stringent enough. He thought that a clause should be inserted to prevent persons who had not received a medical education from taking charge of friendly societies, etc. Whether counter-practice could be put down, he doubted.

Dr. CHRISTISON said that the Council was now only following up a step which had been previously taken. Of the two Bills before Parliament, he considered that that of the Pharmaceutical Society was much the better.

Dr. ANDREW WOOD and Mr. COOPER briefly sup-

ported the motion; which, after some remarks from Dr. ACLAND, was put and carried.

The committee was appointed, to consist of Dr. Acland (chairman), Dr. Alderson, Dr. Paget, Dr. Storrar, Dr. A. Thomson, Dr. Apjohn, Dr. Parkes, Mr. Rumsey, and Dr. Christison.

Practice with One Qualification. Dr. ANDREW WOOD said that Mr. Tucker's letter raised the question of the working of Clause XXXI of the Medical Act. He was satisfied that no practitioner ought to be placed on the *Register* unless he possessed a qualification in both medicine and surgery; and he urged the amalgamation of the Colleges of Physicians and Surgeons for the purpose of examination.

Mr. SYME, Dr. ACLAND, Mr. RUMSEY, Dr. ALDERSON, Mr. ARNOTT, and Mr. COOPER, spoke on the subject; the general opinion being that a qualification both in medicine and in surgery was desirable. As a result of the discussion, the following resolutions were passed.

Mr. ARNOTT moved, and Dr. ANDREW WOOD seconded—

"That a letter be written to Mr. E. E. Tucker, to the following effect. The Council has learned, with great regret, the particulars of the case stated in Mr. Tucker's letter. The Council has not, under the present Act, the power to interfere for the protection of the public against ignorance of surgery on the part of practitioners who have no surgical qualification; but the subject now engages the serious consideration of the Council."

Mr. SYME moved, and Dr. ANDREW WOOD seconded—

"That Clauses XIX and XXXI be referred to the proposed Committee on the Amendment of the Medical Acts."

Convictions under the Medical Act. The following resolutions, both proposed by Dr. EMBLETON and seconded by Dr. FLEMING, were carried.

"That an answer be returned to Dr. Styrap, to the effect that the subjects of his letter of the 3rd March, 1864, are at present under the consideration of the Medical Council."

"That the following four Sections of the Medical Act—viz., XXXVIII, XXXIX, XL, and XLI—be referred to the proposed Committee on the Amendment of the Medical Acts."

The Dentists' Memorial. Dr. STORRAR proposed—

"That the memorial from the Licentiates in Dental Surgery of the Royal College of Surgeons of England be referred to the proposed Committee on Amendment of the Medical Acts."

He said that, while it would be impossible to discuss the question at the present moment, it would be only just to the gentlemen who had signed the memorial that the Council should take their representations into consideration. The licentiates in dental surgery were very desirous of rescuing their profession and the public from quackery; and the necessity of this was obvious from the numerous advertisements which were to be seen in the provincial newspapers. A few years ago, some dentists combined for the purpose of purging their profession of charlatans. At first they desired to form a separate corporate body; but ultimately the majority preferred to be placed under the direction of one of the medical licensing bodies. They had organised a School of Dental Surgery, and were now desirous of being entered on the *Register* according to their qualification as dentists. He did not wish to press the subject at present, but was desirous that the memorial should be duly taken into consideration.

Mr. HARGRAVE seconded the motion.

Mr. RUMSEY suggested that the Council might express a qualified approval of the memorial.

Dr. CHRISTISON said it would be necessary to provide against the risk from entering on the *Register* the names of persons holding the dental qualification alone.

The PRESIDENT and Mr. ARNOTT agreed that it would be dangerous to admit to the *Register* persons being merely licentiates in dental surgery.

The motion was carried.

Visitation of Examinations. Dr. SHARPEY moved, and Dr. STORRAR seconded—

"1. That it is expedient to amend Clause XVIII, by adding to it the following words, or words to the same effect; viz., 'and may also inspect the written answers of the candidates, and report concerning the examinations and answers to the General Council; and to the persons deputed by the General Council as aforesaid, in such number as may be determined by the General Council, with the approval of one of Her Majesty's principal Secretaries of State, there shall be paid such fees for services and such reasonable travelling expenses as shall from time to time be allowed by the General Council, and approved by the Commissioners of Her Majesty's Treasury; and the said payments shall be made out of the residue of the moneys annually received for carrying this Act into execution, after defraying the expenses of the General Council and the Branch Council, and, if necessary, out of further moneys to be provided for the said purpose by vote of Parliament.'

"2. That the proposed amendment be referred to the Committee on the Amendment of the Medical Acts."

Dr. CORRIGAN objected to the motion, and also to the principle of inspection of examinations. He proposed the following amendment, which was seconded by Dr. AQUILLA SMITH.

"That the professional examinations conducted by the several licensing bodies should be public, so far as admitting the Graduates, Members, or Licentiates of the licensing body conducting such examination, and that such publicity will be sufficient to secure the maintenance of efficient examinations without inspection."

After some discussion, in which Dr. ANDREW WOOD, Mr. HARGRAVE, Dr. FLEMING, Dr. A. SMITH, and Dr. SHARPEY took part, the amendment was put to the vote and lost; 5 voting for, and 9 against it.

Dr. ANDREW WOOD moved as a further amendment, and Dr. ALLEN THOMSON seconded—

"That it be remitted to the Committee on the Amendment of the Medical Acts, to consider the expediency of amending Clause XVIII, by adding to it the following words, or words to the same effect; viz., 'and may also inspect', etc. (The remainder of the amendment was identical with the first part of Dr. Sharpey's proposal.)

The amendment was carried, and was then put as a substantive motion, and carried.

Dr. CORRIGAN required that the names of the majority and minority be entered on the minutes. *Majority*—Dr. Alderson, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Thomson, Dr. Sharpey, Dr. Quain, and Dr. Christison. *Against*—Mr. Arnott, Mr. Cooper, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, and Dr. Stokes.

Amendment of the Medical Act. Dr. QUAIN moved—

"That a Committee of the Council be appointed, with the following duties: 1. To report on any further amendments which may seem to be required in the Medical Act. 2. To communicate with the solicitor on the amendments already adopted, or that may be adopted, by the Council. 3. To prepare a memorial to the Home Secretary on the amendment of the Medical Act."

Mr. HARGRAVE seconded the motion, which, after some remarks from Dr. CORRIGAN, was carried; 15 voting for, and 4 against it.

The following Committee was appointed: Dr. Andrew Wood (chairman), Mr. Arnott, Dr. Paget, Dr. Embleton, Mr. Syme, Dr. A. Smith, Dr. Sharpey, Dr. Quain, Dr. Stokes.

Alleged Conviction for Felony. Dr. AQUILLA SMITH moved, Dr. APJOHN seconded, and it was resolved—

“That the case of John Carter Barrett, of Castlebar, Co. Mayo, be referred to the solicitor.”

SATURDAY, APRIL 8TH.

G. BURROWS, M.D., President, in the Chair.

Voting at Meetings of the Council. A case and opinion of counsel, together with an additional statement and further opinion, relative to voting in the Medical Council, were read. Considerable discussion followed thereon; but no resolution was passed.

The Apothecaries' Hall of Ireland. Dr. STOKES moved—

“That with reference to the resolution of this Council, on the motion by Dr. Leet, June 2nd, 1863, viz., ‘That this Council is of opinion that registered Licentiates of the Apothecaries' Company of Dublin are, as apothecaries, entitled to practise medicine in Great Britain and Ireland,’ the Council resolve that it did not desire to convey that the licence of the Apothecaries' Company of Ireland carried any other qualification than that specified in the Act of Incorporation of the Company.”

He recapitulated the previous proceedings of the Council in reference to the privileges of the Apothecaries' Hall of Ireland; and said that his object was not to rescind the resolution passed in 1863, but to define it. The Medical Act conferred no new powers on the licensing bodies; but the Apothecaries' Hall of Ireland had assumed powers which it did not possess before; and in evidence of this he referred to the certificates issued by that body, in which their power to grant licences in medicine was set forth. The position of the apothecaries in Ireland was different from what it was in England. In England, the Apothecaries' Society was specially entitled by an Act of Parliament to examine in medicine; not so the Apothecaries' Hall in Ireland. The only power which they really possessed was that of giving a licence to keep a shop and carry on the business of an apothecary. The Irish Apothecaries' Hall required by law an apprenticeship of seven years; but this rule was now broken. The medical qualification of the Irish apothecaries had been pressed on the Poor-law Commissioners in Ireland, and had been recognised by them; and their example had been followed by the Army Medical Board. It was one of the duties of the Council to see to the proper administration of the Medical Act, and to take care that its provisions were not stretched.

Dr. ANDREW WOOD seconded the motion.

Dr. LEET objected to the motion, that it was contrary to the former resolution of the Council, that it was an incorrect rendering of its meaning, and that it would compromise the honour of the Council. The Apothecaries' Company of Ireland were free to use any form of certificate, and to prescribe any course of education which they might think proper. The greater part of the public in Ireland was dependent for medical aid on the apothecaries; and a legal opinion had been obtained in favour of their registration. The Council had on former occasions declared itself incompetent to decide the question now brought forward. Why was not a *mandamus* brought

against the Apothecaries' Hall, instead of wasting the time of the Council?

Mr. SYME said that the illegal issue of licences by the Apothecaries' Company of Ireland could not be judged by the Medical Council, but was a question for the consideration of the Privy Council. It seemed to be the opinion of some that the Irish Apothecaries' Hall was low, mean, and contemptible. [No, no.] But, if it were so, whose fault was it? The Apothecaries' Company of Ireland had been admitted into Schedule A, and must be treated like other bodies in that schedule. He moved as an amendment—

“That the Council do not see any reason for entering into an explanation of their resolution (June 2nd, 1863) respecting the licence of the Apothecaries' Company of Dublin.”

Dr. STORRAB seconded the amendment.

Dr. ANDREW WOOD said that the question under discussion was more important than at first sight appeared; it was whether the Council had power to grant charters in medicine. The subject of the Apothecaries' Hall of Ireland had been discussed over and over again; and it was only by the able importunity of Dr. Leet that the Council had been driven to give an opinion after having declined to do so. In their proceeding in the matter, the Council had acted illegally, and not consistently with their decision in other instances, such as the rights of the Faculty of Physicians and Surgeons of Glasgow. The result of the action of the Council had been, that the Licentiates of the Irish Apothecaries' Company had assumed the rights of licentiates in medicine.

Dr. CORRIGAN said that the effect of the resolution of the Council had been, that the Irish Poor-law Commissioners had placed the licence of the Apothecaries' Hall of Ireland on an equality with the higher qualifications in medicine. The resolution had also been misunderstood by the Secretary of State for War. No one wished to interfere with the just rights of the apothecaries in Ireland; but their position required definition. Their legitimate status was that of the *officiers de santé* in France; in that position they were most useful to the public; but it was not intended by the resolution that they should be recognised as equal to the higher grades of practitioners. If an attempt were made in France to raise the *officiers de santé* to the level of the higher class of medical men, would it not be said that the profession was disgraced? If the recognition of the Irish apothecaries as fully qualified medical practitioners were correct, the licentiates in midwifery of the Royal College of Surgeons of England ought to have the same privilege. Dr. Corrigan explained to the Council the powers of the Irish Poor-law Commissioners in regard to medical qualifications, stating that these powers were absolute. He also referred to and read extracts from the Apothecaries' Acts in England and in Ireland; and said that the power to grant licences in medicine had been assumed by the Irish Apothecaries' Hall at some period between 1859 and 1864.

Dr. EMBLETON suggested that the subject should be referred to the Committee on Amendments of the Medical Acts. It must be remembered that the Medical Act gave the Apothecaries' Hall of Ireland a representative in the Council, and placed its licentiates in Schedule A.

Dr. STORRAB said that the Council had never decided that the apothecaries in Ireland were to have equal rights with doctors of medicine. The Medical Act made no distinction as to grades of practice. All that the Council had to do was, to take care to secure a sufficient qualification on the part of persons practising medicine.

Mr. HARGRAVE and Dr. ALLEN THOMSON supported Mr. Syme's amendment; and Dr. STOKES replied.

The votes were then taken; when there appeared, for the amendment, 10; against, 6. The amendment was then put as a substantive motion, and carried by a similar majority.

Mr. SYME required that the numbers and names of the majority and minority, and of those who did not vote, should be taken down. *Majority*, 10—Dr. Alderson, Dr. Embleton, Dr. Storrar, Dr. Fleming, Mr. Syme, Dr. Thomson, Mr. Hargrave, Dr. Leet, Dr. Sharpey, Dr. Christison. *Minority*, 6—Mr. Arnott, Dr. Andrew Wood, Dr. A. Smith, Dr. Apjohn, Dr. Corrigan, Dr. Stokes. *Did not Vote*, 3—The President, Mr. Cooper, Dr. Quain.

Preliminary Education. Dr. STOKES moved, Mr. ARNOTT seconded, and it was agreed—

“That a Committee be appointed to consider and report as to what should be the subjects of general education, in which all students should be examined prior to the commencement of their professional studies; the Committee to consist of—Dr. Stokes (chairman), Mr. Arnott, Dr. Acland, Dr. Paget, Dr. Storrar, Dr. Thomson, Dr. Apjohn, Dr. Quain.”

MONDAY, APRIL 10TH.

G. BURROWS, M.D., President, in the Chair.

Medical Education. On the motion of Dr. ANDREW WOOD, seconded by Dr. FLEMING, the Council resolved itself into a Committee on Education; the President in the chair.

Returns from the Examining Bodies. A voluminous series of returns from the examining bodies was reported to have been received; and, after some discussion, it was moved by Dr. CORRIGAN, seconded by Dr. AQUILLA SMITH, and carried—

“That the several communications from the several licensing bodies on the question of education and examination be accepted as read, and printed on the minutes.”

Course of Professional Study. Dr. ANDREW WOOD moved—

“That a Committee be appointed to consider and report on what should be the minimum course of professional study through which all candidates should be required to pass before receiving any qualification entitling them to register.”

He said that the Council had never yet attempted to lay down a course of professional instruction. It was important to do so, not merely as regarded the special subjects, but as to the repetition of courses of lectures. The deficiency in a knowledge of operative surgery mentioned in the report of the Navy Medical Board, also shewed the necessity of taking such a step. He was very desirous that the Council should determine the minimum of lectures and hospital practice which should be required of every candidate for admission into the medical profession. It would not, he thought, be a difficult task.

Dr. EMBLETON seconded the motion.

Dr. CORRIGAN did not think the proposal likely to lead to any practical result; and that it would on every point involve discrepancy of opinion. To attempt to carry it out would be to try to place the licensing bodies on a bed of Procrustes. It would also be unfortunate to lay down a minimum of education; for students would then be satisfied with the lower qualifications in place of presenting themselves to the bodies which required a higher standard of education.

Mr. HARGRAVE said that if a minimum education were fixed, students would not be induced to pass the higher examinations. He entreated the Committee to remove the word “minimum.”

Mr. SYME, Mr. ARNOTT, and Mr. COOPER, also opposed the motion.

Dr. ANDREW WOOD said there was sufficient time to discuss the question if the Council were in earnest. If the Council declined to take the subject into consideration, of what use was it? The Council had been endeavouring to improve the *Register*; and it was also its duty to improve medical education. This was the intention of the Medical Act.

The motion was then put to the vote and lost; 15 voting against and 6 for it.

Dr. ANDREW WOOD required that the numbers and names of the majority and minority, and of those who did not vote, should be taken down. *Majority*, 15—Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Storrar, Mr. Syme, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Apjohn, Dr. Corrigan, Dr. Sharpey, Dr. Quain, Mr. Rumsey, Dr. Christison, Dr. Stokes. *Minority*, 6—Dr. Alderson, Dr. Acland, Dr. Embleton, Dr. Andrew Wood, Dr. Fleming, Dr. Parkes. *Did not Vote*, 2—The President, Dr. Leet.

Dr. CORRIGAN moved—

“That it seems impossible to lay down any scheme of education and examination comprising details which would be applicable to, or could be uniformly carried out by, all the licensing bodies enumerated in the Medical Act; and that this Council is of opinion that the Committee on Education, leaving all details to be carried out in such manner as may appear fit to them by the several licensing bodies, should confine itself, in considering the question of education, to the following points, viz.—

“1. Registration and adequate preliminary examination in Arts.

“2. The time to be interposed between the passing of the preliminary examination and the final examination.

“3. The mode of subdivision of the professional examination, the period of study at which each part of the examination shall be gone through, and the subjects to be comprised in each part.”

After an experience of five years, the impression on his mind was that the Council was not likely to come to any agreement as to the subjects of professional study. They had already found great difficulty in defining what was a medical school, or what courses of lectures should be required. It was impossible to lay down fixed rules as to lectures, etc. There were, however, matters which might well be considered. Efficient registration of students was a matter of primary importance. It was notorious that certificates for past years were given to students who had never attended the courses mentioned; and this would never be stopped until there was a system of registration of students. As to preliminary education, the necessity for care in regard to this was shown by the fact that the Navy Medical Board had rejected several candidates for utter ignorance of Latin. He would say that it was not right to assume always that the licensing body whose diploma the candidate presented was to blame in this respect; inasmuch as the preliminary examination passed at one Board was often recognised by the others. The regulations of the various bodies as to preliminary education varied greatly; for instance, the matriculation examination of the Queen's University was not, he thought, sufficient for students in medicine. The Council accepted certificates of preliminary examination from bodies of whose requirements they were ignorant; and they had no control over these. As to the third part of this resolution, he observed that the Council had only to fix a time between the entrance on professional study and the period of examination.

Dr. SHARPEY seconded the motion. He was op-

posed to all attempts to lay down a system which should be universally applicable. The Council should not do this, but should remedy deficiencies as they occurred. He would not say that Dr. Corrigan's motion comprehended every point that might be considered; but those which it mentioned were among the most important.

Dr. QUAIN called the attention of the Committee to the fact that a Report on Education had been partly discussed last year; and that at present they were making no advance. He moved as an amendment—

"That the Report of the Select Committee on Education of the last session be now proceeded with."

Mr. HARGRAVE seconded the amendment.

The amendment was carried, 10 voting for, and 9 against it; and, on being put as a substantive motion, was carried by a majority of 15 to 3.

Registration of Medical Students. Dr. A. SMITH proposed, Dr. FLEMING seconded, and it was resolved—

"That the Registration of Medical Students be placed under the charge of the Branch Registrars."

Dr. A. SMITH proposed, and Mr. HARGRAVE seconded—

"That every student be registered at the commencement of professional study, the date of such registration to be considered as the date of commencement of professional studies."

After a few remarks from Dr. CORRIGAN and Dr. FLEMING,

Mr. SYME said that annual registration was very important. It had been carried out in Edinburgh during the last forty-two years with great benefit. This registration should be enforced, and the system of certificates abandoned.

Dr. SHARPEY said that the object of registration was to ascertain that the student had passed the preliminary examination, and to ensure his attendance to medical study. He would not interfere with registration in subsequent years.

After some discussion as to whether registration should take place at or before the commencement of professional study,

Mr. SYME moved as an amendment, and Dr. SHARPEY seconded—

"That every medical student shall be registered at the commencement of his professional study, and not until he has passed the preliminary examination."

The amendment was carried; and, having been put as a substantive motion, was also carried.

Dr. AQUILLA SMITH proposed, and Dr. ALDERSON seconded—

"That each of the Branch Registrars shall open a Register of Medical Students from the 1st of April to the 15th of May, and from the 1st of October to the 1st of December, in each year, according to the subjoined form."

(The first column in the form was headed "Date of Registration"; the second, "Name"; the third, "Age last Birthday"; the fourth, "Preliminary Examination in Arts, and Date".)

After a discussion, the following amendment was proposed by Mr. RUMSEY, seconded by Mr. HARGRAVE, and carried—

"That, after the words 'medical students', the resolution read as follows: 'and that application for registration be made by every such student within fifteen days after the commencement of professional study; and that the table be adopted, with the addition of a column for place of study.' (The column of age is also omitted, in consequence of a discussion at a subsequent period of the meeting.)

Dr. AQUILLA SMITH moved, and Dr. APJOHN seconded—

"That every person desirous of being registered as a medical student shall apply (in writing) to the Branch Registrar of the division of the United Kingdom in which he is residing, according to a form to be had on application; and shall produce or forward to him a certificate of his having passed a preliminary examination in Arts recognised by the General Medical Council, and of his place of study; whereupon the said Branch Registrar shall enter his name and other particulars in the Students' Register, and the Registrar shall give him a certificate of such registration accordingly."

Dr. FLEMING moved as an amendment, and Mr. RUMSEY seconded—

"That after the words 'General Medical Council', the resolution read, 'and of his having entered on medical study.'"

The amendment was lost, 3 voting for, and 10 against it. The original motion was carried.

Dr. A. SMITH proposed, and Dr. CORRIGAN seconded, the following resolutions, which were carried.

"That each of the Branch Registrars shall supply to the several qualifying bodies, medical schools, and hospitals in that part of the United Kingdom of which he is Registrar, a sufficient number of blank forms of application for the registration of medical students."

"That a copy of the Register of Medical Students so prepared by the Branch Registrars be transmitted to the Registrar of the General Council, who shall, under direction of the Executive Committee, prepare and print an alphabetical list of all registered students, and supply a copy of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Act."

"That the several licensing bodies be requested not to admit to examination, after October 1869, any candidate for licence or degree whose name does not appear on the authorised list of medical students, or whose name is not already on the *Medical Register*."

"That the several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory."

Dr. ANDREW WOOD moved, Dr. FLEMING seconded, and it was resolved—

"That the Branch Councils be desired to take means to make these regulations known to the medical students at the various medical schools."

The Council resumed.

Committee on Returns from Licensing Bodies. Dr. EMBLETON moved, Dr. ANDREW WOOD seconded, and it was agreed—

"That the returns from the licensing bodies, in compliance with Recommendation 23 of the Committee on Education, and the Registers of Medical Students in England and Ireland, be referred to a Committee; the Committee to consist of—Dr. Embleton (chairman), Mr. Cooper, Dr. Thomson, Dr. Leet, Dr. Apjohn, Dr. Stokes."

On Tuesday and Wednesday, the Council was for the most part engaged, as a Committee on Education, in discussing the Report of the Select Committee of last year. On Wednesday, also, a long Report on the Amendments of the Medical Acts was brought up and read, for the purpose of being printed in the Minutes. We shall report the proceedings more fully in the next number.

THE AMERICAN NAVY. A bill is before Congress for the reorganisation of the medical department of the American navy. It gives increased rank and emolument to medical officers—a reform much needed.

WE beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, APRIL 15TH, 1865.

THE QUALIFIED MAN.

A FEW weeks since, the Governors of the Winchester County Hospital proceeded to elect a gentleman to fill the then vacant post of House-Surgeon and Secretary. Four candidates presented themselves, and sent in their credentials. The contest, however, was limited to a close run between two local competitors. The event has given rise to some provincial discussion. We may, therefore, say a few words on the subject.

Aristotle, in speaking of friendship, says that the legislator appears to pay more attention to it than to justice, and that unanimity of opinion is the best defence against the cabals of faction. Now, we are by no means sure that the advantages of this Athenian virtue may not have been present to the minds of the Winchester governors when they weighed the merits of the respective candidates. The historical and local traditions of the old cathedral city are, no doubt, inseparably interwoven with the daily exercise of one of the commonest forms of friendship—namely, that of hospitality; and it may have appeared to the electors that the law of sympathy should necessarily form an important element in determining their choice of a fit person to fill the office of House-Surgeon and Secretary to their hospital. Nor does the fact, that this choice excluded the gentlemen who possessed the highest professional testimonials, at all either invalidate the soundness of the election, or place the unsuccessful candidate in a less commanding position.

There has lately been given in the JOURNAL an analysis of the sources from which the ranks of the Army Medical Staff are recruited; and two significant facts may be deduced from a careful examination of this analysis. First, we are compelled to acknowledge that, with all its elaborate machinery for ensuring a high style of professional education, the army fails to attract the best class of men. In the next place, we may fairly draw this inference from the consideration of the foregoing fact, that something more solid than a mere scientific training is looked for by the student himself in an age of refinement to compensate for the perils and penalties of a life of certain toil and uncertain reward. A

Medical Council, or an Army Board, may declare their system of education to have the sanction of the highest authority, and, therefore, to be the most beneficial and best adapted to the wants of human society; but there is not yet such a convenient ductility in the human mind, as to make us capable of being persuaded that men can possibly mean the ultimate good of mankind by curtailing the privileges of the agents who are to effect that good.

These difficulties, however, are always undergoing the process of "finding their level." The demand of the old-fashioned Governors of Winchester Hospital for something besides medals and certificates points to a state of things that is fast making its way into the centres of social life. They could not be induced to believe that there is a forge and manufactory for doctors separate and distinct from that original anvil on which the manners of all educated gentlemen are hammered out and softened. They could scarcely believe in the existence—certainly, not in the propriety—of an abstract science detached from the rest of the world of literature, and amusing itself with the puppet-show of a public institution. They had always considered it an axiom, that learning is a confederacy; and any interdict to the communion of science with the art of applying it they would have regarded as fatal to the success of science as a means of benefiting mankind.

Of one thing we may now be tolerably sure, that Medical Councils, Examining Boards, and Schools of Medicine, must revise their codes. The honours and distinctions that are awarded in our schools under competitive pressure are, no doubt, evidences of one description of proficiency, without which the most indefatigable labour would be barren of the highest kind of fruit; but this is not all that is wanted—the real utility, as well as the dignity, of every employment wholly depends upon the quantity and the kind of ability that may be exerted in it. The great qualities of the physician's mind, which are not merely enduring and passive, require force for their display—we had almost said, for their unequivocal existence. The art, therefore, of applying knowledge, which is the mainspring of all intellectual power, becomes a necessary ingredient in the curriculum of the medical school. It is on this account, also, that the science of speculative and practical reasoning, which, in combating disease, must take to its aid so many auxiliary branches of knowledge, stands high in the estimation of the wisest and best men. We have no desire to abridge the present methods by which medals and other prizes are given and obtained; but we desire to see greater credit bestowed on qualifications, in virtue of which the physician is hereafter to hold authority over the public mind.

Theoretically, the distinguished student who is decorated with his orders is best fitted for service; but, as a matter of everyday practice, as we have seen on

a late occasion, the candidate in possession of a more collective wisdom is judged to be "the right man in the right place."

THE ACTION OF THE LIVER ON FOOD, ETC.

WHAT is the function of the liver, is still an unanswered question. The researches of Bernard, Dr. Pavy, and others, have not yet told us the whole of the physiology of that organ, although they have told us very much of it. Bernard's theory of the glycogenic power of the organ is denied by Dr. Pavy; and Dr. Pavy's view is now supported by Dr. Robert McDonnell.*

That the liver secretes bile, all the world knows, and has long known; but what it does in addition to this, is what we have yet to learn, and want to know. Modern discovery seems to indicate that the mere secretion of bile is probably the least important part which the organ plays; or rather, we should say, that the secretion of the bile is only one part of its complex function; that, while it is secreting bile, it is also forming some other important materials—perchance some blood-constituents. Its power of making and storing up an amyloid (starchy) substance in the liver is certain, as Bernard showed; but Bernard, we are now told, erred in supposing that this glycogenic (amyloid) matter is converted into sugar, which passes into the hepatic veins, and is consumed in the lungs, producing heat. Dr. Pavy denies this, and has given very strong experimental facts to show that during life, and under natural conditions, the amyloid matter is never converted into sugar. And, in support of this view, it has been argued: Let those who assert that the amyloid matter is converted into sugar, and used up as a heat-producer in the respiratory process, tell us what becomes of the amyloid matter which is formed and used up in the tissues of the foetus before respiration begins. Dr. McDonnell agrees with Dr. Pavy that, during life and health, the liver does not convert its amyloid matter into sugar. He holds that its conversion into sugar during life is a deviation from the healthy process. What, then, becomes of this amyloid matter in the liver? Dr. McDonnell believes that the liver is

"A great blood-making organ, in which there is constantly going on a reconstruction of certain ingredients of the blood; that in it the fibrine, etc., which has done its work, is disintegrated; the hydrocarbons of the bile abstracted; and the nitrogen combined with amyloid substance, which, instead of being normally changed into sugar, emerges from the liver as a constituent principle of the protoplasma."

This is the theory which Dr. McDonnell discusses experimentally in his pamphlet. He first of all ex-

amines and corroborates Dr. Pavy's facts tending to show that the amyloid substance is not transformed into sugar during health and life. He then inquires into the physiological relations of the amyloid substance; and, lastly, into the characters, etc., of the blood which enters, and of the blood which leaves, the liver; and from his experiments deduces the conclusions above given.

One very important practical lesson is to be drawn from these physiological investigations. Bernard, Dr. Pavy, and Dr. McDonnell are all agreed in this, that amyloid substance may be formed in the body out of nitrogenous articles of food. Also it appears, if Dr. McDonnell's views be corroborated, that not only can this body of man convert albuminous, nitrogenous, food into starchy, carbonaceous, food, but that it can also, through the liver's aid, convert amylaceous matter into a nitrogenous base. Enough, at all events, is taught us by these valuable experiments; and it is this—that the fascinating theories of Liebig on food, which have now so long and still so firmly possess the minds of the public and the profession, require reconsideration. Look only at one single article of diet, so largely used in our hospitals: we mean beef-tea. Consider its enormous consumption, and, therefore, its immense cost; and then let us ask ourselves: Are we sure—have we any sound basis on which to rest the conclusion which we seem so unhesitatingly to have embraced—that in using beef to make beef-tea, and feeding the sick on it, we are acting wisely and economically—using all the nutrition in the beef, and giving the sick the best kind of food? We beg to suggest that, in the matter of this one article of diet, there are very fair reasons to believe that we are, in fact, yearly squandering away the funds of our hospitals; in other words, that we are wasting very large and very expensive quantities of food, and deluding ourselves as to the food—we mean really nutritive matter—which we give our patients. If, for example, a pound of beef, free from bone and fat, is to be converted into a pint of beef-tea (which, if boiled down, would not contain, perhaps, more than half an ounce of solid matter), is it not reasonable to suggest that the greater part of the *meat* is absolutely wasted? Are we really to believe that all the solid materials—the *bouilli*—left after the manufacture of the soup, is useless as food? More than this: Are we sure that this beef-tea is really the best and most agreeable nutriment which we can give to the sick stomach? We sincerely trust that some of our large hospitals, where the consumption of beef-tea is very large, and where it must figure as a very serious item of expenditure, will seriously take this question into consideration. We verily believe that, in this matter, the professional and the public mind is labouring under the charm and delusion in which they have been caught by one of Liebig's fascinating formulæ. We will venture to

* *Observations on the Functions of the Liver, etc.* By Dr. Robert McDonnell, Surgeon to Jervis Street Hospital, etc., Dublin.

say that it has never yet been *proved* that the beef-tea à la *Liebig*, or any other way manufactured, really does possess those highly nutritive qualities usually ascribed to it. And we may add, that the way of using meat now so extensively employed by physicians in St. Petersburg, and especially for sick children, is well worthy the general attention of the profession: we mean, as raw meat chopped up very fine, and made into a savoury mass. Trousseau and other Paris physicians employ and speak in very high terms of meat thus administered.

THE session of the Medical Council is again a rather long one. Saturday is the earliest day at which it is expected that the business will be completed. Our report of the proceedings in this day's JOURNAL commences with some reports from the Directors-General of the Army and Navy Medical Departments, to an analysis of which we may probably have to return next week. The Amendments of the Medical Acts are, at the time when we write, under the consideration of a Committee. The Council has, after years of consideration and inaction on the subject, at last resolved to organise a system of supervision of the examinations held by the different licensing boards. On Saturday, the greater part of the time of the meeting was occupied by a debate on the old question—the privilege of the Irish Apothecaries; and the result of three hours' talk was, to leave the matter precisely where it was. During the present week, the Council has been chiefly occupied in discussing the report of the Select Committee on Medical Education, which was brought up and partly considered last year.

DR. WATSON, in thanking the Royal College of Physicians for again electing him President, said that he bowed to the honour expressed by the College, but still would have been grateful had another been elected in his place, from feelings of misgiving as to his ability to fully discharge the duties of office. Now, for the fourth time, he had had conferred on him the highest professional honour. Hitherto, the courtesy and kindness of the Fellows had made the duties of office both easy and pleasant; and he doubted not that he should still enjoy the same assistance. There were but few events which required comment. Government had applied to us for advice, etc., and their questions we have answered. Our doors have been opened to public bodies; and at this moment the Medical Council is enjoying our hospitality. Good and able lectures have already been given, and extra ones are announced for this year. The College has secured a lease of its premises for 999 years. The Harveian Oration will in future be given in English—a thing

to be glad of; for it will thereby become more attractive and intelligible to the profession at large, and yield more of credit to those who deliver it. Latin composition, from whatever cause, is a less common accomplishment than it was formerly. The Treasurer will give us a tolerably satisfactory balance-sheet; but much money has been spent on improvements in the College. The number of Fellows is now precisely what it was last year: five have been added to the list, and five have died. The Fellows who have died are Dr. Wood, Dr. J. Bird, Dr. Kirkes, Dr. Duke, and Dr. Turner. Dr. Turner was the oldest Fellow in the College; he was 93 years of age, and being blind had of late years lived in great seclusion. He delivered the Harveian Oration in the old College. He was once the Treasurer; and also Physician to St. Bartholomew's Hospital. He was in his time a very sociable and popular gentleman; he left no literary remains. Dr. Kirkes was esteemed and beloved by all who knew him. He was cut off in his prime, at a moment when the highest position in his profession was opened before him. He deserved all he had obtained in reputation. He was modest and gentle; and was distinguished for his goodness and his blameless and pious life; and his memory will be cherished by all who knew him.

THE Report of the Committee appointed by the College of Physicians to inquire into the condition of the army and navy medical officers was on Monday last read to the College. After some slight discussion, it was resolved that the Report should be printed and circulated amongst the Fellows of the College, and considered at the next meeting of the College, on the 21st inst.

MR. ROPER, Secretary to the South Western Branch of the Association, was on the 9th instant, elected Surgeon to the Devon and Exeter Hospital, in place of the late lamented Mr. W. W. James.

DR. GREAM opposes the views of Dr. Marion Sims respecting the enlarging of the os uteri by incision. Dr. Sims, says Dr. Gream, "repudiates dilatation as dangerous in all its aspects, and declares that division of the cervix is as safe as dilatation is hazardous." Dr. Gream adds, that he has been repeatedly consulted by women who had had the os uteri divided for sterility; and never, except in one single instance, has he known a case in which pregnancy followed; and in this case the woman aborted, because the artificial opening was so great as to prevent the womb retaining its contents. He could also, he says, relate of cellulitis, pelvic abscess, etc., following incision of the cervix. Dr. Gream considers the only proper treatment is slow and carefully managed dilatation, in properly selected cases.

YOKOHAMA IN 1864.

BY A MEDICAL OFFICER OF THE ROYAL NAVY.

NO. I.

I suppose that the present state of affairs in Japan is creating some interest at home, in spite of its remoteness, in spite of the very small number of people who know anything or care anything about the country. Acting on this supposition, I propose to give you some account of Yokohama, the chief foreign settlement in Dai Nippon, or Great Japan, as the natives proudly term it. And I shall endeavour to tell a true tale, trying to steer clear of the fairy-like romance in which some writers have clothed their descriptions, and equally so of the somewhat uncharitable trueness which others have displayed.

Yokohama is situate on the western shore of the Gulf of Yedo, and occupies one side of a bay or bight on the other shore of which is Kanayawa. Hence, probably, its name "yoko", meaning across, and "hama", a strand. The town is situate on a triangular alluvial flat, bounded on the base by the sea and on each side by low wooded ranges, which converge to a point distant from four to six miles from the shore. Viewed from the harbour, the appearance of the town is mean; no buildings of any pretension existing, and the majority of the houses being low and without ornament. A canal connected with the sea separates the concession and the Japanese quarter from the paddy swamps and flat lands behind. And a capitally constructed bund, with two commodious *katoba*, or piers, defend the frontage of the settlement from the encroachment of the sea, which often rages with considerable force when the wind blows into the harbour. The harbour itself is extensive, easy to enter, and tolerably free from shoals or rocks. It is, however, exposed, and the wind and sea are often so high that no embarking or disembarking of cargo can be effected.

On each side of the above-mentioned alluvial, the scenery is very beautiful. Irregular precipitous cliffs of argillaceous sandstone, thickly wooded on their summits to the very edge, offer an imposing barrier to the violence of the sea. In many places, the alternating strata of gravel, of shell *d'bris*, and vegetable mould, show the successive upheavals and sinkings so common in volcanic districts. Looking inland, the country appears to consist of irregular wooded ranges, with deep intervening glens, backed up by a line of mountains, averaging (I should think) from 4000 to 5000 feet, above which towers in solitary grandeur Fusi Yama, a mountain of the true volcanic shape, now (December) almost entirely covered with snow. Generally, even throughout the summer, the snow does not entirely disappear, though sometimes it remains visible only in crevices and sun-sheltered spots. Fusi Yama, or Fuji San, as the Japanese generally call it, is said to have a height of 12,000 feet.*

Of the foreign quarter, or Honmoora, nearly all, if not quite all, is taken up, and the greater portion already built upon. The Japanese quarter, which is more extensive, occupies the north. As to the population, I have no data; but I should estimate the foreigners (exclusive of officials and soldiers or sailors) at 200 or 300, two-thirds of whom, at least, are

English. The Japanese may number, taking in the suburbs, 8000 or 10,000, or even more; but this is a mere guess.

In the foreign quarter, as in the Japanese, the streets are neither paved nor lighted, and in wet weather are almost impassable. The foreign streets are wide, and have most of them open drains, constructed by the Japanese government. The houses are detached, built with verandahs, and roofed in the Japanese fashion, the "arêtes" being formed of white or chequered tiles. Some are built of stone, or at least faced with it; but many are entirely of wood, lath, and mud. The wooden houses are exceedingly strong, and resist earthquake shocks much better than those of stone; but have the disadvantage of being very liable to conflagration. They are distinguished by numbers, according to nationality—thus, "Oran no in Ban", or "Holland No. 2"; "Ingirisy H'yak' Ban", or "English No. 100".

On the south side, Honmoora is bounded by the canal, which is crossed by several wooden bridges, giving access to a straggling village on the opposite side, behind which is the cemetery. At the remote end of each bridge, Japanese guard-houses are placed, and indeed at every entrance into the town. The guards are supposed to prevent Ronin and other bad characters from entering the settlement. From the Japanese quarter, Honmoora is separated, at sunset or at dusk, by closed gates; only a small wicket, guarded by Yakunins, being left open for necessary passage. After dark, foreigners are not allowed to enter native dwellings, places of amusement of course excepted, as this is against Japanese "custom".

In the native quarter, the streets are dirty and narrow, with one or two exceptions. In the lower portions, next the swamp, they are especially so, and are infested by a thousand unpleasant smells. Here, too, small-pox, fevers, and cholera, sometimes commit fearful ravages. The sewerage, or refuse, is got rid of after the Chinese method, and is distributed on the lands around the town, the sudden perception of which fact often diminishes considerably one's rapture at the natural beauties of the neighbourhood.

The houses are nearly all of them of wood blackened on the exterior, and generally of one story only, except in the case of well-to-do merchants or the higher officials. The back and front are generally quite open, or closed by wooden screens, or by wooden frames with panes of paper in lieu of glass. In the front room the inhabitants live, eat, and sleep, while a small chamber behind serves as scullery, etc. The floor is raised a foot or two above the ground, and is always covered with a thick, very evenly plaited or woven straw-matting, laid down in strips of about a yard wide, and often having the edges bound with black cotton cloth, so as to give a very pretty relief to the somewhat bare apartment.

A kind of wooden trough, or metal vessel, half filled with gravel and a peculiar grey sand, contains a small charcoal burner, round which the family may be generally seen, working, eating, drinking little cups of tea, or smoking a very finely cut and fragrant tobacco, in small-bowled, long-stemmed pipes. Smoking is commonly practised by all, even by young girls, and all appear to take great pleasure in it, puffing it slowly through the nostrils with evident satisfaction. The introduction of opium is forbidden; and one meets none of the lamentable victims of over-indulgence in that drug so commonly seen in China.

There is but little furniture; nothing but a few cupboards or shelves, and perhaps a few mats, on which they sit, or rather squat, the calf being bent up against the back of the thigh, a most uncomfortable position for those who are not accustomed to it.

* Fuji San means "unequalled" or "peerless" mountain. Yama and San both mean mountain; the former being the indigenous Japanese word; while the other, the more commonly used in this instance, is a Chinese importation.

In every house, too, there is sure to be fixed up in some corner a kind of cage- or box-like structure containing an image or picture of some god, with a number of small joss-sticks burning slowly away in front of it, and a number of little cups and trays containing sweetmeats, bits of fish, or little heaps of rice, all of which is supposed to propitiate the deity. Generally, too, a number of strips of paper, with moral sentences extracted from the sacred books written on them, are to be seen hanging in front of the miniature temple. The image is generally a fat looking man, with his face distended by a broad grin, heavily gilt and rudely ornamented. When they pray to these, their Lares and Penates, they commence by several low reverences, and then, earnestly rubbing their hands together, rapidly mutter a short invocation or prayer. Sometimes, on certain festival days, the little temple is ornamented with flowers, real or artificial, and has an extra allowance of joss-sticks. Altogether, it much resembles what one sees in China; but there is an absence of the tawdriness, tinsel, and dirt, so essentially Chinese.

The principal streets are the Honcho and the Benten Dosi. In the latter, reside most of the silk merchants; in the former, are the lacquer, porcelain, and *curio* shops. There are many temptations to spend money; the articles exposed for sale being novel in form and design, and withal elegant and tasteful—beautifully lacquered cabinets, glove-boxes, *et hoc genus omne*, with corner clamps and lock-plates of silver or bronze, more or less elaborately carved. Instead of metal, porcelain plates, embellished with various designs, groups of flowers, natural objects, etc., are often used; and sometimes, again, the whole surface of the cabinet is covered with these. I need not here describe the exquisite ornamentation of these objects; but I must give a passing word of praise to the fidelity with which natural objects are portrayed.

The antique lacquer is of high value, and much more rare than the modern. I have seen specimens for which 1200 dollars were asked. The price of a good cabinet of the ordinary kind varies from 30 to 300 *ichibos**; but the shopkeepers invariably ask you nearly double the price which, if you exercise a little patience, they will eventually take.

The articles of bronze are of graceful form, and are very elaborately ornamented. Here, again, antiquity greatly enhances the value. Vases, of all kinds and sizes, variously embellished with designs of animals, flowers, gods, etc., curiously shaped monsters, trays of all sorts, charcoal-holders, candlesticks, are the objects generally met with. A curious kind of cylindrical vase, of tolerable thickness, is used as a gong, giving, when struck, a loud, prolonged, and very harmonious tone. Some bronzes are curiously inlaid with gold or silver, chiefly in very thin meandering lines.

Tortoise-shell is worked into a variety of forms; small vases, cups, boxes, and trays. Some of these latter are from ten to twenty-six inches in diameter, and all are more or less decorated with gold lacquer in relief.

Ivory is used also, and images, carvings, small cabinets, etc., are made of it. The cabinets are very pretty; and generally have represented on them some popular tale in a series of relief carving. The very delicate carving of the Chinese is not, however, to be found in Japan.

Their porcelain is, also, of excellent quality; but, I think, inferior in design to the Chinese. A peculiar variety, called egg-shell porcelain, is, however,

superior to anything I have seen in China, and the best examples of this are to be procured at Nagasaki.

In buying articles of lacquer, porcelain, or ivory, one has to be very careful in examining the designs; or purchases are made, embellished in so objectionable a manner—to English eyes, at least—that they can never be exhibited at home.

I do not intend to give any account of the silk stuffs, as they are inferior to Shanghai silks, and are, moreover, fully described in most works on Japan. There are innumerable other *curios*, which I have only space to enumerate: prettily worked chains and cigar-cases of strips of bamboo or silken cord; hair ornaments of tortoise-shell or metal; crystal balls, sometimes of very large size, and much prized by the Japanese, who consider them safeguards against evil or bad luck; cigar-cases or tobacco-pouches, of strong paper, beautifully ornamented; Japanese pipes of bronze or silver, and ornamented by animals, flowers, etc., in high relief; inimitable tops that spin for forty minutes, and are very much superior to anything I have ever seen of the sort in Europe; various musical instruments, the most common resembling a banjo; charms of all kinds, in silver or bronze, often minutely inlaid and engraved, and many other *curios*, some of a very obscene nature.

I will now ask the reader to accompany me in a walk through the best part of the Japanese town. Landing at a solidly constructed "hatoba", or pier, passing by the place where boats are hired at the rate of four *tempos* each boat, passing by the "Unjyosho", or Custom House, a large square of buildings of blackened wood, let us get at once into the Benten Dosi, the principal business street. And, first, we must pass through a kind of market, through a crowd of vendors and buyers of fruit, fish, etc., and of keepers of small booths, where native stomachs are supplied with bits of fried eel, of boiled "tako", or cuttle-fish (esteemed a great delicacy), with indescribable cakes of half-baked dough filled with some nameless compound, with small bowls of "meshi", or boiled rice, and tiny cups of "ochya", or tea. The people turn for an instant to look at the "too jin san", or "far away people"; some grinning pleasantly enough, some inviting you to inspect their wares, some saluting you courteously with their usual morning salutation, "O hayoo" (meaning, "You are early, sir"), which sounds marvellously like "How are you?"; perhaps, a few boys, or an idle coolie running after you with his bamboo and net, hoping to gain a few *tempos* by carrying home your purchases. Entering the Benten Dosi through the Yakunin guarded gate, we mingle with the busy crowd of people in this the Fleet Street of Yokohama. We may be lucky enough to see the O Bungioo Sama,* or Governor, pass by; and we shall be warned of his approach by the cries of his forerunners, "Sh'ta ni iro; sh'ta ni iro"—"Down with you; down with you". At which, the people bow themselves to the earth while the great Kami goes by in his chair, preceded, surrounded, and followed by an irregular array of two-sworded men, bearers of halberds, and long poles armed at the extremity with re-curved hooks, and probably one or two standard- or device-bearers. The great man himself will be dressed much as a common Yakunin, unless he be on some state service or visit.

The two-sworded men are very numerous, some making purchases, some sauntering lazily along, many of them Custom House clerks going to or returning from their duties. Those in green capes are,

* The *ichibo* has a fluctuating value of 238-250 for 100 dollars; and dollars again vary in value from 4s. 9½d. to 5s. 1d.

* Sama, sometimes contracted into San, is a title of honour. It is placed after the name which is often preceded by O: thus, "O Hana San", or Miss Hana; "O Jones San", or Mr. Jones.

I believe, retainers of the Taikun. All seem to carry a "mon", or device, worked upon their outermost robe, on the back and on each sleeve. As a rule, they are very civil and readily make way for you.

If two acquaintances meet, their politeness is overpowering—an endless series of profound bows, accompanied with courteous expressions in a curiously modulated tone of voice, and ushered in generally by a peculiar, long, noisy indrawing of the breath, which appears to be indispensable. Even the commonest coolies are exceedingly courteous; and it is often amusing to watch the profound reverences exchanged between a couple of fellows, either next door to naked, or having a scanty clothing reduced to such an extremity of rags and patches that to make out the original fabric would be an impossibility.

Many of the lower orders are dressed in firemen's costume, having on their backs and sleeves a curious rectangular pattern.

The "akindo", or merchants, are quiet, shrewd-looking men, plainly dressed, and carrying no sword. Their business is not carried on altogether without risk, as the news just received from Yedo, that some dozen of the silk merchants there have been murdered by Ronins, will teach us.

Business appears brisk. Bales of cotton and silk, chests of tea, etc., are being conveyed in carts drawn by two men in front, aided by two men or more behind, all of them encouraging each other by a kind of vociferous song. Coolies are trotting about with heavy loads slung on bamboos. Itinerant pedlars are exhibiting their wares. Conjurers are endeavouring to gather an audience by a semblance of performing wonderful tricks which they are always on the point of doing and never do. Of course, there is the usual beggar, generally a woman, with a small diseased child, the blind man with stick and dog, with the addition here of a shrill whistle, and the never failing musician executing dolorous airs on a melancholy "samushen", from which all harmony has long since departed. The clerical profession is represented by the various grades of Bōz San, or priests of Buddha or Sintoo. The lower orders of priests dress much like the laity; but their heads are always completely shaven. Those of higher rank, who are not often seen in Yokohama, wear a costume not very unlike the vestments of a Roman Catholic priest. They are, I believe, very much respected by the people; though the inferior ones would not seem to be so, as it is an usual thing that Yakunin or other persons who have in any way offended the laws of Japan are permitted to escape punishment by becoming priests—so, at least, many Japanese have informed me. I should imagine it to be a leap from the frying-pan into the fire; for the clergy are very poor, are vowed to celibacy, and are strict vegetarians, not even eggs or fish being allowed them, and their life must be one of very few pleasures indeed.

Further down the street is a bath-house; and it is to be noticed that there are two entrances, with inscriptions over them denoting that one is for women and one for men. On entering, however, it is seen that there is only one room divided by a low partition. Both parts are attended by male servants, who bring hot water and towels, and even assist in the washing process itself. Though the whole is open to the street, the interior is so dark that nothing can be perceived scarcely, unless one approaches for the purpose. I never saw a Japanese take any such notice. Europeans only are seen sometimes lounging at the entrance. I never saw the men bathers at all mingle with the women, though, undoubtedly, they might do so; and, in answer to many inquiries of

mine, the natives have said that scarcely any one would think of doing so.

And, in Yokohama at least, all the baths appear to be conducted on the same plan. I am here merely stating what I have seen; and do not at all mean to deny the oft-asserted fact of the very immoral tendency of Japanese civilisation. For evidence of this is abundant in the loose conversation of both men and women, in the articles and books exposed publicly for sale, and in their ornamental designs even on such high-priced articles as to be only within the reach of the well-to-do.

Yokohama is at present very lively. The harbour is full of ships, English, French, American, Prussian, and Dutch; and the streets ashore are crowded by blue jackets and naval and military officers of all nationalities. Nor is there a deficiency of amusements. The fleet gives, from time to time, theatrical entertainments, of more than commonly high amateur excellence, both aboard and ashore; we have had instrumentals, singers, and conjurers, from Shanghai; there is a capital United Service Club; and there are frequent military displays, marches on the Takaido, etc., with bands playing—a healthful exercise for the men, and a pleasant sense-of-security-giving sight for the residents.

During the present cold weather, there is football every afternoon on the bluff, well attended by residents and officers; and for those who are not active enough for such rough sport, there are beautiful walks and rides in nearly every direction, pleasures which may now safely be indulged in, as an European patrol visits all the principal roads within a circuit of four miles of Yokohama. A great deprivation, however, is the not being permitted to shoot, a restriction very bitterly felt, and the more so because game of all kinds—pheasants, wood-pigeons, teal, snipe, wild ducks, etc.—is exceedingly abundant. The native population appears to be very well affected towards us. Capital domestics are obtained at from ten to fifteen thyibos a month; and are always very glad to come and very sorry to be sent away. If you take a walk into the country, the "hyaksho", or farmers, are always very civil and good-natured, and like nothing better than to be allowed to inspect your clothes, watch, buttons, etc.; a process which they accompany by an animated dialogue, always asking the price, and signifying their admiration by exclamations of "Naru hodo", an untranslatable expression, answering perhaps to our "Is it possible?"—a much more harmonious word than the Chinaman's "Hai yah".

The Yakunins,* too, are invariably polite; though sometimes at night they may become abusive when inflamed with "sake".† Probably, they are all picked men with strong reasons for behaving themselves. Around Yokohama, and at all the entrances, are guard-houses, where all comers have to produce admission-papers. These guards, however, do as much harm as good, because they act as restrictions upon commerce. In the vicinity of Yokohama, however, and especially in the direction of Yedo, there is always a chance of meeting some drunken Yakunin or some wandering Ronin,‡ as unhappily exemplified in the recent murders of Major Baldwin and Lieutenant

* Yakunin (literally office people) government employees, whether in a military or civil capacity, or whether in the service of the Taikun, or of any local Daimio. They have the privilege of wearing two swords, but are not by any means of noble birth. Any of Chōo-nin (literally street people), or common people, may enter government service, and so become a Yakunin.

† Sake, a species of spirit made from rice, not very strong, and always taken warm.

‡ Ronin. According to Japanese accounts, these are men who have been outlawed; or, from reason, have been obliged to quit the service of their Daimios. The meaning of the word appears to be "worn out" or "useless".

Bird. Such accidents, however, might be always averted, or nearly always, if people would but have the caution of not walking or riding out far (and especially towards Yedo), excepting in parties of at least three, all armed with revolvers. Attacks of this kind have, in nearly every case, been made upon defenceless persons.

EDINBURGH UNIVERSITY CLUB.

THE success of this union of the graduates and members of the University of Edinburgh is very remarkable. Already the Club, not yet one year old, numbers two hundred; and, before the year is out, we may be sure it will reach to at least three hundred. On Saturday last, the Club had a most successful reunion at Willis's Rooms. Between sixty and seventy members of the University sat down to a dinner, where haggis and whisky were not forgotten. Dr. Christison presided, and was flanked and supported by Dr. Roget, Dr. Copland, Mr. Syme, Dr. Andrew Wood, and numerous eminent representatives of the army and navy medical services, as well as of civil practice. Dr. Christison and Mr. Syme received from their former pupils an ovation which could not fail to have been deeply gratifying to them. As was remarked by one of those present on the occasion, nothing is more characteristic of the teaching of the professors of the Edinburgh University than this, that the students leave the University not only imbued with respect and admiration for their teachers, but also with feelings of deep and lasting friendship towards them.

CHEMISTS AND DRUGGISTS BILLS. The select committee on the Chemists and Druggists Bills is composed of the following members:—Sir Fitzroy Kelly, Sir J. Shelley, Lord Elcho, Mr. Baring, Dr. Brady, Mr. H. Russell, Mr. C. Wynn, Mr. Ayrton, Mr. Selater-Booth, Mr. Cox, Mr. Schneider, Sir J. Ferguson, Mr. C. Forster, Mr. Roebuck, and Mr. Black.

A COUNTRY HOSPITAL AND SISTERHOOD NURSES. The committee of the General Hospital in Bristol have almost surpassed their neighbours in Gloucester in prejudice and intolerance. As the nursing of that hospital was acknowledged to be defective, and as an amendment ought always to follow upon admission of evil, an effort was made to introduce the system of nursing which has for several years been carried on successfully in University and King's College Hospitals, and recently in that at Charing Cross. It was proposed that a sisterhood should undertake the nursing of the Bristol General Hospital upon a system similar to that which was found to succeed so admirably, and although the highest and most reliable testimony was given to the practical advantages which had followed the adoption of this system in those hospitals, while the obvious and serious disadvantages perpetually arising from the deficiencies of their own, were avowedly experienced and openly regretted, the people of Bristol, or at any rate their representatives on the Hospital Committee, have set aside this proposition, and have declined to give it a trial, out of a servile deference to the clamour of senseless bigotry. In other words, they have sacrificed the true interests of a great public institution to prejudice. (*The Church Times.*)

Association Intelligence.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE next meeting will be held at Dartford, on Friday, April 28th, at 3.50 P.M.

Dinner at 5.

Flaxman Spurrell, Esq., will preside.

Further particulars will be given next week.

FREDERICK J. BROWN, M.D., *Hon. Sec.*

Rochester, April 12th, 1865.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. At a general meeting of the Fellows, held on Monday, April 10th, 1865,

Watson, Thomas, M.D.Cantab., D.C.L.Oxon., was unanimously re-elected President of the College for the ensuing year.

At the same meeting, the following gentlemen, having undergone the necessary examination, were duly admitted members of the College:—

Brodie, George Bernard, M.D.St.Andrews, 10, Bolton Row
Gee, Samuel Jones, M.B.Lond., 46, Queen Anne Street
Shore, Offley Bohun, M.D.Edin., Stamford
Thurgar, Benjamin Bingay, M.D.Edin., 35, York Street, Portman Square
Warter, John Southey, M.D.Edin., 23, Frederick Street, Gray's Inn Road

At the same meeting, the following gentlemen were reported by the examiners to have passed the first part of the Professional Examination for the Licence of the College:—

Davies, Nathaniel E., St. Bartholomew's Hospital
Harwood, Alfred, Guy's Hospital
Hallett, Lyttelton, St. Bartholomew's Hospital
Jackson, Mowbray, St. Bartholomew's Hospital
King, Osmer, Guy's Hospital
Leverton, Edward James, St. Bartholomew's Hospital
Mules, Philip Henry, St. George's Hospital
Nettleship, Edward, King's College
Orme, Campbell, St. Bartholomew's Hospital
Reid, Lestock Holland, St. Bartholomew's Hospital
Richards, William Alespt, King's College
Tattersall, William James, St. Bartholomew's Hospital
Tibbits, Herbert, St. Bartholomew's Hospital
Tindale, Wentworth Raynes, St. George's Hospital
Truman, Samuel John, Guy's Hospital
Unton, Herbert Chrippes, St. Bartholomew's Hospital
Wright, Matthew Hall, Birmingham

ROYAL COLLEGE OF SURGEONS OF ENGLAND. At the meeting of the Council, on April 5th, the following were admitted Fellows of the College.

Griffith, William, Oswestry
Snape, Richard Forth, Bolton-le-Moors

APOTHECARIES' HALL. On March 30th, 1865, the following Licentiates were admitted:—

Brewer, Charles Claridge, City Road
Burrell, Edwin, Westley, Bury St. Edmunds
Sturton, Hubert Wilson South, Trafalgar Road, Greenwich
Williams, John, University College

As an Assistant:—

Lloyd, John, George Street, Cardiff

Admitted on April 6th—

Busby, Ralph Alexander, Royal Free Hospital
Douglas, George Cox, Grantham, Lincolnshire
Evans, Edward Charles, Cardiff, South Wales
Harris, Charles James, King William Street, Charing Cross
Herbert, Henry Edward, Charing Cross Hospital
Morgan, Lewis Wayne, The Hafod, Pontypridd, Glamorganshire
Ruffe, Frederick, Tamworth
Stuckey, John, Langport, Somersetshire
Wright, Charles James, East Parade, Leeds

At the same Court, the following passed the first examination:—

Coalbank, Isaac, St. Bartholomew's Hospital
Cuddeford, Thomas, St. Bartholomew's Hospital
Finch, John E. M., St. Bartholomew's Hospital
Fisher, Frederic Richard, St. George's Hospital
Hay, Thomas Bell, University College Hospital
Sherwin, John, King's College Hospital
Tattersall, William James, St. Bartholomew's Hospital
Upton, Herbert Chrippes, St. Bartholomew's Hospital
Wright, Matthew Hall, Sydenham College, Birmingham

APPOINTMENTS.

ARMY.

BOURKE, Assistant-Surgeon G. T., 51st Foot, to be Staff-Assistant-Surgeon, *vice* R. W. Lawless.
BURNSIDE, Staff-Assistant-Surgeon G. S., to be Assistant-Surgeon 51st Foot, *vice* G. S. Bourke.
KERANS, Assistant-Surgeon W. R., Supernumerary in 19th Foot, to be Assistant-Surgeon 11th Foot.
LAWLESS, Staff-Assistant-Surgeon R. W., to be Assistant-Surgeon 23rd Foot, *vice* F. A. Turton.
MULLINS, Staff-Surgeon-Major J., to be Surgeon 2nd Dragoons, *vice* Surgeon-Major A. P. Lockwood.
SWAN, Surgeon W. G., M.D., 19th Foot, to be Surgeon-Major, having completed twenty years' full-pay service.
TERTON, Assistant-Surgeon F. A., 23rd Foot, to be Assistant-Surgeon Royal Artillery, *vice* R. White.

ROYAL NAVY.

BERNARD, Robert, Esq., Staff-Surgeon, to the *President*.
BLAKE, Frederick W., M.D., Surgeon, to the *Narcissus*.
BOLTON, Abraham J., Esq., Assistant-Surgeon, to the *Frederick William*.
DOBYN, John S., Esq., Assistant-Surgeon, to the *Narcissus*.
GRANT, William, M.D., Acting Assistant-Surgeon, to the *Mutine*.
HAMBURY, Ingham, Esq., Assistant-Surgeon (addit.), to the *Sutlej*.
HILSTON, Duncan, M.D., Assistant-Surgeon, to the *Victory*.
MARTIN, James, M.D., Surgeon, to the *Mutine*.
MARTIN, J. H., Esq., Acting Assistant-Surgeon, to the *Narcissus*.
WATSON, Alexander, M.D., to be Surgeon-Superintendent of the Racehorse convict-ship.

VOLUNTEERS. (A.V. = Artillery Volunteers; R.V. = Rifle Volunteers):—

BENNETT, G. H., Esq., to be Surgeon 1st Northumberland A.V. Years.
DAVIS, A. A., Esq., to be Surgeon 1st Administrative Brigade Cornwall A.V.
LITTLETON, W., Esq., to be Honorary Assistant-Surgeon 22nd Cornwall R.V.
SHIPMAN, R., Esq., to be Assistant-Surgeon 3rd Lincolnshire R.V.

DEATH.

MACKENZIE, Frederick W., M.D., at 11, Chester Place, Hyde Park Square, aged 48, on April 3.

A NEW HOSPITAL. The erection of a small hospital at Petworth is in contemplation.

MR. HESTER has resigned the surgeoncy of the Oxford Infirmary.

DR. COBBOLD has been engaged by the College of Surgeons to remodel the collection of entozoa in the museum.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN. The seventy-seventh anniversary dinner of this Society will be held at the Albion Tavern, in Aldersgate Street, E.C., on Wednesday, the 26th inst., at half-past six o'clock; Martin Ware, Esq., President, in the Chair.

THE RUSSIAN EPIDEMIC. The Medical Department of the Council have already despatched Dr. Whitley to St. Petersburg, and Dr. Sanderson to Dantsic and Elbing, to report upon the alarming epidemic. Dr. Thudichum will proceed to another chief seat of the disease. (*Observer*.)

CONSANGUINEOUS MARRIAGES. The general feeling of the people, as communicated to me, is distinctly against consanguineous marriages, which they regard as "bad for the offspring." One shrewd old woman, however, added this important remark,— "But I'll tell ye what, Doctor, bairns that's hungert i' their youth aye gang wrang. That's faur waur nor sib marriages." (*Dr. Mitchell*.)

ROYAL NAVY. The sum of £64,800 has been voted for medical stores.

A VILLAGE HOSPITAL is being built at Capel, Surrey, at the expense of a benevolent lady.

PRIZES OF THE ROYAL COLLEGE OF SURGEONS. At a meeting of the Council on the 6th inst., a Jacksonian Prize was awarded to Mr. William Adams, F.R.C.S., of Henrietta Street, Cavendish Square, Surgeon to the Royal Orthopaedic Hospital, for the best essay on Club-Foot, its Causes, Pathology, and Treatment; and a special *honorarium* was also awarded to Mr. John Crown Agnis, F.R.C.S., Surgeon to the Royal Horse Guards, as the author of the next best essay on the same subject. The other Jacksonian Prize was awarded to Mr. Thomas Annandale, formerly of Newcastle-on-Tyne, but now of Edinburgh, for his essay on the Malformations, Diseases, and Injuries of the Fingers and Toes, with their Surgical Treatment. There were no competitors for the Collegial Triennial Prize on the Structural Anatomy and Physiology of the Lymphatic Glands and Vessels; nor for the other Jacksonian Prize, on the Diseases of the Ankle-joint, and of the Joints and Bones of the Tarsus, requiring Surgical Treatment.

TESTIMONIAL TO DR. COOKWORTHY. A very handsome library chair has been presented to Dr. Cookworthy by some of the patients of the Plymouth Public Dispensary, as a mark of their estimate of his kind attention, during more than half a century, to the afflicted poor of that town. At the head of the chair, amid carved oak-leaves, is placed a silver-gilt shield bearing the following inscription:—"Presented to Dr. Cookworthy by the patients of the Plymouth Public Dispensary, as a token of gratitude for the valuable services rendered for a period of fifty years. February 7th, 1865." In the year 1848, the governors of the dispensary commemorated the fiftieth anniversary of the institution, by placing Dr. Cookworthy's portrait in the physician's room, and by giving him a valuable tea service; and again on his retirement, after fifty years' tenure of office, presented him with an elegant and costly table centre-piece.

THE PRITCHARD CASE. From all we can learn amid the close secrecy preserved it would appear that the quantitative analysis in the case of Mrs. Pritchard is nearly, if not quite, completed, with the result, we hear, of showing that exceptionally large quantities of tartar emetic or tartarised antimony were lodged in the tissues, especially of the stomach. The extent to which the body appears saturated with the drug would seem to indicate that its administration had extended over a long period. In explanation of the erroneous rumour regarding the deceased lady, to the effect that she was in the habit of using wine, we may mention that it may not impossibly be shown that during her fatal illness, the delirium of an apparent fever was induced by the administration of sparkling wines and anaesthetics. At the first there would appear to have been, among scientific men, a suspicion that monkshood had been an agent in the death of Mrs. Pritchard; but it is understood that this suspicion has not been supported by the analysis. On Friday Professor Penny of the Andersonian University, Glasgow, visited Edinburgh, having been called in by the authorities to aid in the investigation, with the view, if required, to corroborate evidence. With regard to the inquiry into the causes of the death of Mrs. Taylor, the authorities in Glasgow have received a communication from Edinburgh, to the effect, we believe, that the appearances presented in the body of the deceased lady were not of the nature that might have been expected had

death resulted from paralysis or apoplexy, as certified by Dr. Pritchard when he registered death. This report, however, of course, has no application to the chemical analysis of the organs of the late Mrs. Taylor, which is now only in process. (*Scotsman*.)

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY.Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY.....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY. Pathological Society of London, 8 P.M.—Statistical.—Anthropological, 8 P.M.
WEDNESDAY. Meteorological.
THURSDAY. Harveian Society of London, 8 P.M.—Royal.—Zoological.—Linnean.—Chemical.
FRIDAY. Royal Institute.

TO CORRESPONDENTS.

. All letters and communications for the JOURNAL, to be addressed to the Editor, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

ERRATUM.—In Dr. Noble's letter on Medical Evidence, at p. 361, it is printed: "No assumption either of 'undoubted importance' on the one side, or of 'disastrous mischief' on the other." For importance read imposture.

MEDICAL SOCIETY OF LONDON.—The meeting of this Society, which was fixed for Monday, April 17th, is postponed until Monday, April 24th.

MR. JAMES DOWIE, whose name is doubtless known to some of our readers as one who has long earnestly attempted to get mankind to wear rational shoes, has just published a little pamphlet to enforce his views. It is called "On the Motions of the Human Feet, and the Means of Preserving them Unimpaired, being the Philosophy of Shoemaking."

MEDICAL LATINITY.—At a late examination at a College of Physicians, one of the candidates, who had to translate a passage from Celsus, in which were the words *cubare moliter*, wrote them down as "smoke slightly". No doubt, the gentleman must have been under the influence of a Cuba at the time. We are surprised that he did not render the preceding words in a like fashion. *Oportet conquiescere* might just as fairly have been turned into "go to bed on a bottle of port". If our readers will turn to the Reports of Examinations by Army and Navy Directors, in to-day's JOURNAL, they will probably come to the conclusion, that primary education amongst medical students is in a retrograde state of development. Does the fact of the College of Physicians giving up its Latin oration, illustrate this condition of the modern medical mind?

THE ENDOSCOPE.—Dr. Dick has referred to the Endoscope of M. Desormaux, in his Monograph on Gleet; and also in the *Transactions of the Pathological Society* for 1863, p. 136.

TYPHUS OR PLAGUE.—T. W. writes: "Our best pathologists regard typhus fever and plague as similar diseases—the latter being only an intensified form of typhus. Your correspondent Dr. Barclay seems to have overlooked this in his argument, that the disappearance of plague from this country is a proof of change of type in diseases. Dr. Murchison, in his work on Fevers, points out the similarity between the two diseases, and expresses his opinion that 'plague is probably the typhus of warm climates'. At the present moment, when the public mind is excited by plaguey telegrams, it may be well to notice this fact. I have heard also, that Clot Bey (the French doctor naturalised in Egypt), when he once visited the Fever Hospital of London, remarked upon a case of typhus which he saw there: That if it had occurred in Egypt, he should have called it a case of plague."

GOVERNMENT INSURANCE FEES.—SIR: Could not the example of the Metropolitan Counties Branch be followed up by a memorial, signed by our President and by Sir Charles Hastings, on behalf of the Association? Is it not also a question for the Colleges? The money loss to the profession is a small part of the business. By quietly submitting to this proposal, we confess that a detailed medical report (involving sometimes an hour's labour, sometimes more) is worth from 2s. 6d. to 5s. If this be so, how can I consistently decline "taking less than a guinea". I have done this hitherto, and done it effectually, feeling that if my report was not worth a guinea, it ought to be; but there must be some mistake, if the seven hundred and the *Lancet* are right. Who am I, that I should say my opinion is eight, or even four times as good, as that of my neighbour, Dr. Smith? But, whatever is done, let us avoid the mistake of making it a doctor's grievance; it is a public question. Let it be plainly seen that we wish to help the Government; that we admit the difficulty; but, at the same time, we feel it due to our profession to protest against a tariff which will infallibly issue in obtaining and encouraging inferior service. We wish the work to be well done, that is all.

I am sorry to see the *Medical Times* and *Gazette* countenancing the indignity.
 Derby, April 3rd, 1865. I am, etc.,
 WILLIAM OGLE, M.D.

THE GRIFFIN TESTIMONIAL FUND.—SIR: The following subscriptions have been further received on behalf of the above Fund:—Richard Grimby, Esq. (Banbury), £1; Richard Mallam, Esq. (Banbury), per Mr. Grimby, 5s.; Jeremiah McGreal, Esq. (Banbury), per Mr. Grimby, 5s.; Thomas Elkington, Esq. (Southam), per Mr. Grimby, 10s.

Amount previously announced, £120 3s 6d.
 I am, etc., ROBERT FOWLER, M.D.,
 Treasurer and Hon. Sec.
 145, Bishopsgate Street Without, April 12th, 1865.

COMMUNICATIONS have been received from:—Mr. WILLIAM COPNEY; Dr. DURRANT; THE HONORARY SECRETARIES OF THE BATH AND BRISTOL BRANCH; Dr. F. J. BROWN; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; Dr. B. W. RICHARDSON; THE SECRETARY OF THE ODONTOLOGICAL SOCIETY; Dr. RADFORD; Mr. GAMAGE; Dr. NOBLE; Mr. JOHN CLAY; Dr. T. J. WALKER; Mr. STEELE; Rev. J. INGLE; THE REGISTRAR OF THE MEDICAL SOCIETY OF LONDON; Dr. BEREND; Dr. R. FOWLER; and Mr. T. M. STONE.

BOOKS RECEIVED.

1. Report of the Northampton Lunatic Asylum for 1864.
2. Workhouse Hospitals. By J. H. Stallard, M.D. Lond. London: 1865.
3. A Dictionary of Science, Literature, and Art. Edited by W. T. Brande, D.C.L., and the Rev. G. W. Cox, M.A. Part I. London: 1865.

ESTABLISHED 1843.
MEDICAL TRANSFER & PROFESSIONAL AGENCY.
50, Lincoln's-inn-fields, W.C.

Mr. J. Baxter Langley, M.R.C.S.
(KING'S COLL.), has now upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements, and no expense incurred (except in special cases) unless a negotiation be completed.

The General Partnership and Commercial Agency business till recently conducted by him at his City offices, and his experience in the management of large commercial undertakings, combined with his professional acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned.

Mr. Langley can refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers, and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.
Office Hours, from 11 till 4; Saturdays from 11 till 2.

Competent Assistants provided
without delay, free of expense to the Principals. No gentlemen recommended whose antecedents have not been inquired into. Apply to Mr. Langley, 50, Lincoln's-inn-fields, W.C.

Locum Tenens can be despatched
by an early train, after receipt of letter or telegram, stating terms, duties, and qualifications required.—Fee, 10s. 6d. Address Mr. Langley, as above.

Medical Assistants. — Wanted
Immediately, several competent In-door and Out-door ASSISTANTS, qualified and unqualified, for Town and Country. No charge for registration, but references in all cases required. Apply to Mr. Langley, 50, Lincoln's-inn-fields, W.C.

St. George's Hospital Medical
SCHOOL.—The SUMMER SESSION commences on MONDAY, MAY 1.

LECTURES.
Midwifery—Dr. Robert Lee, F.R.S.
Materia Medica—Dr. Barclay.
Practical Chemistry—Dr. Noad, F.R.S.
Botany—Dr. Maxwell Masters.
Medical Jurisprudence—Dr. Fuller.
Pathology—Mr. Henry Lee.
Dental Surgery—Mr. Vasey.

On the payment of a compensating fee of £100, a pupil becomes perpetual to the Practice of the Physicians and Surgeons and to all Lectures, may compete for all Prizes, Exhibitions, and for the Office of House-Surgeon, Medical and Surgical Registrar, and may become Clinical Clerk and Dresser for two periods of three months each.

On the payment of £30—one half, £15, to be paid at the commencement of the First Summer Session, and the other half, £15, at the commencement of the Second Summer Session—a pupil will be admitted to the Hospital Practice and Lectures required for Examination by the various Examining Bodies.

Gentlemen can enter to the Hospital Practice and Lectures separately, or to any one Course of Lectures.

The Hospital contains 350 beds. Clinical Lectures are delivered by the Physicians and Surgeons every week.

A MATERNITY DEPARTMENT, for the delivery of married lying-in women at their own homes, is established at the Hospital; and a Ward is devoted to the reception of women suffering under diseases peculiar to the sex.

The following Prizes will be awarded at the termination of the Session:—

Sir Charles Clarke's Prize for Good Conduct.
The Thompson Medal.
Sir Benjamin Brodie's Clinical Prize in Surgery.
The Lewis Powell Clinical Prize in Medicine.
The Henry Charles Johnson Memorial Prize in Anatomy.

A General Examination will be held at the end of the Session, and a Certificate of Proficiency given to each Pupil who passes to the satisfaction of the Examiners, and the following Prizes to the most distinguished, viz.:—

A Prize of Ten Guineas to Pupils in their First Year.
A Prize of Ten Guineas to Pupils in their Second Year.
A Prize of Ten Guineas to Pupils in their Third Year.

Further information may be obtained from Dr. Barclay, the Treasurer of the School, from any of the Lecturers, or from Mr. Hammerton, at the Hospital.

St. Bartholomew's Hospital and
MEDICAL COLLEGE.—LECTURES.

SUMMER SESSION, commencing MAY 1, 1865.

Materia Medica—Dr. Farre. Botany—Dr. Harris.
Forensic Medicine—Dr. Martin. Midwifery—Dr. Greenhalgh.
Compar. Anatomy—Mr. Callender. Practical Chemistry—Dr. Odling.
The Hospital contains 650 Beds, and Clinical Lectures are delivered—on the Medical Cases by Dr. FARRE, Dr. BLACK, and Dr. MARTIN; on the Surgical Cases by Mr. LAWRENCE, Mr. PAGET, and Mr. COOTE; and on Diseases of Women by Dr. GREENHALGH.

COLLEGIATE ESTABLISHMENT.—Students can reside within the Hospital walls subject to the Collegiate regulations. Some of the teachers connected with the Hospital also receive Students to reside with them.

Seven Scholarships, varying in value from £20 to £50, are awarded annually. Further information respecting these and other details may be obtained from Dr. Edwards, Mr. Callender, or any of the Medical or Surgical Officers or Lecturers: or at the Anatomical Museum or Library.

St. Mary's Hospital Medical
SCHOOL.—The SUMMER SESSION will commence on MONDAY, MAY 1.

LECTURES.

Clinical Medicine—Dr. Alderson, F.R.S., Dr. Sibson, F.R.S., and Dr. Handfield Jones, F.R.S.
Clinical Surgery—Mr. Lane, Mr. Ure, and Mr. Spencer Smith.
Midwifery—Dr. Tyler Smith and Dr. Graily Hewitt.
Practical Chemistry—Dr. Matthiessen, F.R.S.
Botany—Dr. Christopher Dresser.
Materia Medica—Dr. Sieveking.
Medical Jurisprudence—Dr. Randall.
Ophthalmic Surgery—Mr. Ernest Hart.
Comparative Anatomy and Zoology—Mr. Mivart, F.L.S.
Natural Philosophy—Mr. Balmanno Squire, M.B., F.L.S.

A Maternity Department is attached to the Hospital, from which Pupils can attend cases; and Ophthalmic, Aurial, and Dental Departments. Courses of Surgical Operations on the dead subject for Army, Navy, &c.

Students can receive Private Instruction in Practical Pharmacy in the Dispensary of the Hospital—Fee for Three Months, £3 3s.

Class Examinations are held during the Courses, and Prizes are awarded at the end of each Session.

Further information may be obtained on application to ERNEST HART, Dean of the School.

St. Mary's Hospital, April, 1865.

Guy's Hospital—Medical and
SURGICAL SCHOOL.—The Summer Session will commence on Monday, May 1st. For prospectus apply to Mr. Stocker, Apothecary.—Guy's Hospital, April 6th, 1865.

Midwifery and Diseases of
WOMEN & CHILDREN.—Dr. MATTHEWS DUNCAN, F.R.C.P.E., will commence his Course of Lectures on the above Subjects, on the 3rd May, at 10 a.m., in the Medical School, No. 4, High School Yards. This Course qualifies for all the Academic, Collegiate, and other Boards.

Fee for First Course £3 5 0
Fee for Second Course 1 3 0

Dr. D. will also continue to give Instructions in Practical Midwifery, at the Royal Dispensary, on Tuesdays and Fridays, at 1 p.m. A Class for Females will be commenced in November. Intending Pupils are requested to apply at 30, Charlotte Square, at Two p.m.

Hospital for Sick Children,
49, GREAT ORMOND STREET, W.C.

Notice is hereby given, that a vacancy has occurred for an ASSISTANT PHYSICIAN to this Hospital. Candidates, who must be Fellows or Members of the Royal College of Physicians of London, are invited to send in their applications and testimonials on or before Wednesday, April 19th.

By order of the Committee of Management.
SAMUEL WHITFORD, Secretary.

Pepsine and Pepsine Wine.—

M. BOUDAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Her Majesty's Chemist, 277, Oxford Street, London, to whom all applications respecting it must be addressed.

Third Edition of Boudault on "Pepsine", with further Remarks by Dr. Corvisart, Physician in Ordinary to the Emperor of the French; edited by W. S. SQUIRE, Ph.D. Published by J. Churchill, London. May also be had of the Author, 277, Oxford St. Price 6d.

Surgical Instruments.—Arnold
& SONS continue to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under their own superintendence.

ARNOLD & SONS, 35 and 36 West Smithfield, E.C.
Established 1819.

OF

HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

HULL GENERAL INFIRMARY.

LITHOTOMY FOR THE SECOND TIME: RECOVERY.

Under the care of W. J. LUNN, M.D.

[Reported by Mr. T. M. EVANS, House-Surgeon.]

WM. WINTER, aged 35, admitted on November 8th. His health had been pretty good, but his urine contained a deposit of pus; and micturition was frequent, and followed by much pain. A stone was readily detected with the sound, having a rough, but not very irregular surface, and apparently not of large size. He had been lithotomised seven years before by Dr. Lunn, and made a good recovery; the stone weighed an ounce and three-quarters, and was most remarkably nodulated and irregular—a fine specimen of the mulberry calculus. Since that time, he remained well till a year ago, when he first felt a return of his former symptoms; but he continued at work till the last few days.

Nov. 26th. Under chloroform, the lateral operation was performed; the incision being made close to the cicatrix. But there was some difficulty in removing the stone, which broke up into a great many fragments; these were removed with forceps, and the bladder then washed out till nothing further could be felt. The stone consisted of phosphates laminated.

After the operation, he did well for a time, except that he had a rather sharp attack of bronchitis; but on January 11th, as there was still pain in the bladder, a purulent deposit in the urine, and the wound unhealed, a sound was introduced, and a stone distinctly felt. The next day, a lithotrite was passed, and the stone partly broken, though there was much trouble in seizing it, apparently from its being adherent or sacculated. Several small fragments passed with the urine during the following days, and the operation was repeated twice with the same result.

On February 27th, a small fragment became lodged in the urethra, and was removed with urethral forceps. This appeared to be the last of the stone, for none could afterwards be detected; and he was discharged on March 10th, quite well, except for an occasional deposit of pus in the urine, to which he had been subject ever since the first operation.

EXCISION OF OS UTERI FOR CARCINOMA: DEATH FROM PERITONITIS.

Under the care of W. J. LUNN, M.D.

Harriet Cook, aged 37, married, without any family, regular in menstruation, but having suffered from pain at the lower part of the body, and a constant offensive discharge during the last twelve months, was admitted on February 17th. On examination, the os was felt low down, patulous, and hardened, slightly ulcerated, and bleeding readily; the cervix elongated, and freely moveable. Her sister died of cancer of the tongue.

March 10th. The patient having been put fully

under chloroform, the os was well drawn down with hooked forceps, and then excised with scissors. There being free hæmorrhage, lint dipped in perchloride of iron and glycerine was applied, and the vagina then stuffed with dry lint. After recovering from the operation, she suffered much pain. She was ordered to take half a drachm of tincture of opium immediately.

8 P.M. There had been considerable further hæmorrhage. The lint was therefore removed, and the vagina replugged with the aid of a speculum; a catheter having been first passed. Twenty minims of tincture of opium were given.

March 11th. She had a pretty quiet night, but seemed very weak this morning. There was no further bleeding. Pulse 150, and feeble; tongue inclined to be dry. She had no vomiting, but great thirst. She was ordered to take twenty minims of laudanum immediately, and an effervescing draught every three hours; and to have four ounces of brandy.

March 12th. She was weaker to-day, and the pulse had risen to 160; but in other respects she was much the same.

March 13th. She had slept very little, and vomited frequently a green bilious fluid. The tongue was coated; there was no action of the bowels; pulse 160, and extremely feeble; abdomen tympanitic, with much pain and tenderness at the lower part. The mucous membrane of the vagina was sore, hard, and coated with coagulated blood. The vagina was thoroughly washed out with warm water, and an enema administered. She was ordered to take every three hours an effervescing draught, with five minims of laudanum and ten minims of chloric ether. The vomiting continuing unrelieved, she was ordered a grain of opium (in pill) every three hours, and a mustard poultice to the epigastrium; but she sank, and died after a few hours. No *post mortem* examination was allowed.

ABSCESS OF THE KIDNEY: DEATH FROM PERITONITIS.

Under the care of Sir HENRY COOPER, M.D.

Ben. Olssen, aged 24, a Norwegian sailor, was admitted December 6th, 1864. In the right hypochondriac region, low down, was a prominent swelling, of three or four inches diameter, rather firm, but distinctly elastic to the feel, though there was no sense of fluctuation, and apparently connected with the liver, which was to be felt reaching down to the lower border of the tumour. It was very painful, but not tender.

The patient was feverish and thirsty, with an sanguine but not jaundiced complexion. He had been ill only twelve days, the first appearance of the tumour dating from the same time. He had had neither rigors nor dysentery. He was ordered to have half an ounce of castor-oil, and milk diet.

Dec. 8th. The swelling had somewhat increased in size. The motions were rather pale. He was ordered ten grains of nitrate of potash three times a day, and ten grains of Dover's powder every night.

Dec. 10th. He was slightly jaundiced, and the urine was tinged with bile. The bowels were confined. Two calomel and jalap pills were given at bedtime.

Dec. 12th. The jaundice was less marked, bilious stools having been passed. The urine still contained bile. There was not so much fever, but the swelling was larger and more elastic.

Dec. 13th, 9 A.M. The swelling had entirely disappeared; and there was now acute tenderness all over the abdomen, with much pain. His expression

was anxious; pulse 116; and tongue furred. A little bile had been vomited. One-sixth of a grain of hydrochlorate of morphia was given every four hours.

7 P.M. He had vomited a great quantity of greenish fluid; and lay with his knees drawn up, suffering much pain. The abdomen was very resonant and tender.

Dec. 14th. His expression was haggard; pulse very feeble and irregular. He had great thirst, and constant vomiting of green fluid, amounting to four pints in the twenty-four hours; no action of the bowels; abdomen very resonant; respiration entirely thoracic. He had passed a restless night. A pill, containing a grain of calomel and one-sixth of a grain of morphia, was given every four hours.

Dec. 15th. The vomiting and constipation continued. The abdomen was less resonant at the upper part, and quite dull, with distinct fluctuation below the umbilicus. He was ordered to have an enema of beef-tea, with half a drachm of tincture of opium.

Dec. 16th. He was somewhat improved; pulse 112, and of fair volume; tongue cleaning. He was still vomiting large quantities of fluid, which was now of a yellow tint. There was no action of the bowels; the injections of beef-tea had been retained. The abdomen was less tender, resonant on the left side, dull on the right, and fluctuating in the right iliac region. The enema was repeated.

Dec. 18th. He was much emaciated, and his eyes sunken. The vomiting and constipation continued. Percussion of the abdomen yielded the same results. A blister was applied to the epigastrium; and he was ordered to take every three hours an effervescing soda draught, with one minim of hydrocyanic acid (Scheele's).

Dec. 20th. The abdomen was now resonant all over. There was still the same vomiting and constipation; and two large injections, containing castor-oil, had been retained. Pulse 100, very feeble. At night, a profuse sweating came on; and he died at nine the next morning.

AUTOPSY. There was much general peritonitis, the intestines being glued together with recent lymph. The ascending colon was pushed over towards the left side; and occupying its place was a cyst containing fluid, which would hold about three pints, extending as high as the under surface of the liver (which was much displaced upwards), and backwards to the psoas muscles, in which it lay. It consisted of the kidney, or its pelvis, enormously distended, and filled with pus; all trace of kidney-structure having disappeared, except one small portion and three much dilated calices. It was every where adherent by lymph; and, in separating it from the liver, an escape of pus took place through a rent in the sac. The liver itself was healthy. The left kidney was of three times the natural size, but sound in structure.

THE LANCET AND THE AMERICANS. The *London Lancet*, in a notice of the defence of the late Surgeon-General of the United States Armies, makes it the occasion of very undignified and uncalled for vituperative and sneering remarks about the Government and people of the United States. As ardent as is the hatred of a majority of certain classes of the English of our country and its institutions, we think that a medical journal is scarcely the place in which to make exhibition of it. That surely is not the legitimate work of a medical journal. (*Philadelphia Med. and Surg. Reporter.*)

Original Communications.

ON THE PHYSICS OF DISEASE, AND THE PHYSICAL PATHOLOGY OF THE BLOOD.

By BENJAMIN W. RICHARDSON, M.A., M.D., Senior
Physician to the Royal Infirmary for Diseases
of the Chest.

CHAPTER III. (continued from p. 167.)

The Oxidation of Blood. Effects of Ozonised Air.

IN the first part of this chapter, published in the *JOURNAL* of Feb. 18th, I demonstrated the influence of active or ozonised pure oxygen. I proceed now to show the effects produced by the respiration of ozonised atmospheric air. In this series of inquiries, the chamber delineated at page 84 was employed, and the air was ozonised by means of Siemen's instrument, also described on page 84 of the *JOURNAL*. In all cases, the animals were well fed previously to the inhalation, and the air introduced was at first feebly ozonised; moreover, they were placed in the chamber for some little time before the ozone was driven into it, in order that every sign of excitement might subside. Lastly, in the experiments, the temperature of the air was sustained at 60° Fahr., and was allowed to rise above that degree according as was desired. It is important to remember, in respect to the influence of temperature in experiments with ozonised air, that marked physiological effects are not elicited at a temperature below 60°. At 50°, the influence is almost nil.

Inhalation of Air Saturated with Ozone. Synthesis of Congestive Bronchitis.

Air ozonised to the fullest possible degree, and at a mean temperature of 63° Fahr., was passed through a chamber containing a guinea-pig and a rabbit. Both animals were in good condition; the rabbit had been fed mainly on green vegetables and bran, the guinea-pig on bread and milk with a little vegetable. The current of air, passing from the ozone-tube to the chamber, was very brisk, and the escape from the chamber was most free; so that there was no possibility of accumulation of carbonic acid. I myself inhaled the air issuing from the escape-tube of the chamber several times; it was always powerfully strong of ozone, and irritating to the nostrils and throat. After inhaling it for a time, it conveyed the idea of being heavy to breathe, and it produced some headache, which quickly passed away.

In a few seconds after the commencement of the inhalation, the animals began to show signs of irritation. The breathing soon afterwards was quick, laborious, and deep. At the end of an hour, the guinea-pig was breathing four to one, as compared with the rabbit. At the close of an hour and a quarter, the rabbit was breathing hoarsely, with the head thrown back and without movement as though it were comatose; the guinea-pig showed no sign of coma, but was breathing at the rate of 120 per minute.

The inhalation was continued for two hours, when the animals were removed from the chamber. The chest of each was now carefully examined with the stethoscope. Both animals were breathing quickly,

and in both there was the hoarse, dry, cooing murmur of respiration, which is so definitely characteristic of the first stage of bronchitis. The heart-beat was quick and embarrassed, and the skin was hot and dry. The guinea-pig was in every sense the most affected. After ten minutes, both animals were placed in their ordinary hutch. Very soon afterwards, the guinea-pig began to sink, and died. The rabbit continued to breathe quickly, and for some hours was indifferent to food and feverish. The mucous membrane of the nose and mouth was also dry and injected. On the following day, the respiration was still quickened; but the dryness of respiration had given place to a moist *râle*. On the third day, the animal may be considered as having recovered.

Immediately after death had taken place, the body of the guinea-pig was quickly opened. The right side of the heart was found congested with blood; and the kidneys and all the vascular organs were greatly congested. The lungs were ecchymosed; in parts, their structure was as white as milk; in other parts, there were deep congested spots of the size of a pea, into which blood was effused. The bronchial surface was not congested; but was covered with a frothy tenacious mucus, which exuded from the lungs in all parts where they were incised. The blood underwent moderately quick coagulation, but its colour was not materially modified; the venous blood was, perhaps, more than usually dark; and the arterial, by contrast, was markedly red. These were the natural conditions of the blood of the animal, in a degree peculiarly well developed.

In this experiment, we gather very important and useful information. We see, in a word, an induced bronchitis—a true synthesis of disease. If a man had been exposed out of doors to ozonised air, and had returned home with similar symptoms of disease, quick pulse, hot skin, rapid breathing, and dry coarse respiratory murmur, we should not hesitate for a moment in our diagnosis. If he died rapidly, and we found the morbid conditions presented by the guinea-pig, we should undoubtedly return the disorder that killed as congestive bronchitis. If he recovered with free secretion on the bronchial surface, as the rabbit did, we should style the affection acute bronchitis terminating by resolution. It does not seem to me that the formulæ of the artificial and of the natural disease admit of distinction or difference.

It is worthy of note that, in the experiment thus recited, the air was saturated with ozone. It may be asked on this, whether the same train of symptoms would follow if less activity of oxygen had been produced. I have an answer to that inquiry at hand. Fourteen days previously to the performance of the last experiment, the very same animals were exposed to a current of ozonised air for the same period of time. On that occasion, the air was ozonised to not quite half the same degree as before, and the temperature of the air was five degrees lower. Then both animals manifested symptoms of the same character precisely as on the later occasion; but the symptoms were not so intense. Both animals had rapid breathing, hurried circulation, and coarse respiratory murmur; but on being removed from the active air, they recovered without a bad sign.

Lastly, the rabbit had, with another rabbit, been made to breathe air partly charged with ozone at a temperature of 56° Fahr., one month previously to the second experiment. It and its fellow then exhibited similar symptoms; but, after two hours' inhalation, it recovered on removal into the open air. I was aided in all these inquiries by my friend Dr. Wood; and no element, as far as we could see, was wanting to make the research complete and free from

objection. The apparatus was most simple, the working easy, and the proceedings of each successive step were conducted carefully and without haste. The same care was taken in the experiments related in my previous paper, where oxygen itself was employed.

Taking the whole series of experiments into consideration, I do not think there can be a doubt that ozonised oxygen, on being inhaled, produces, as its first degree of action, catarrhal irritation of the mucous membrane of the mouth, throat, and nostrils; as its second degree, extension of irritation to the bronchial surface, and bronchitis; and, as its third, exudation into the structure of the lung, molecular change in the blood, with separation of fibrine, a form of general inflammatory fever and death.

And now the great and vital question to be considered is:—Whether we, as occupants of this earth and enclosed in a vast chamber of atmospheric air, are ever exposed to oxygen in such active condition that it shall light up in us the same symptoms as can be artificially induced in the inferior animals. The question would seem to admit of easy solution, and all the elements for its solution may, in truth, be present; but it is surrounded with difficulties nevertheless. The great difficulty lies in this, that we have no correct and ready means of measuring, or I had better say of estimating, the extent to which air is charged with ozone. All the rules on this point, as at present supplied, turn out, in practical work, to be fallacious tests. They may show presence; but they do not show quantity beyond a certain degree. The ozone-papers discolour up to a given depth; then they cease to act, and not only so, but on exposure they are apt to become discoloured by other agents, and it seems now that they may lose colour in the air, so that the maximum they have registered may be lost. We have, therefore, as yet, but an imperfect guide as to the presence of ozone and no guide as to the intensity of its action. Further, the determination of the actual presence of ozone may be obscured by other substances which do not probably interfere with its action upon the organism.

Something may be taken into account here in respect to common sensation. I know that, during easterly and north-easterly winds, I have breathed air which to sensation is as much like ozonised air as can well be compared; and I have experienced from such air the same effects as come from ozone—viz., irritation of the throat and nose, and catarrh. In some instances of this kind, the ozone-paper has demonstrated ozone; in others, it has not. Is the test here at fault? I think so. Any way, of this we may be convinced—that ozone cannot possibly be present in the air for many hours, at a temperature above 55° Fahr., without producing in those subjected to its influence some shade of effect. It would not affect all with the same degree of intensity; it does not do so in the course of actual experiment, but in many it would of necessity give rise to catarrh, to bronchitis, to pneumonia, or even to croup.

THE ADMINISTRATION OF OPIUM IN OBSTRUCTION OF THE BOWELS.

By THOMAS JAMES WALKER, M.D., Surgeon to the Peterborough Infirmary and Dispensary, etc.

SEVERAL communications have recently appeared in the pages of this JOURNAL advocating the use of opium in strangulated hernia and in ileus; and although this treatment has no claims to novelty, examples of the mistaken practice of administering

purgatives in these cases are too frequent to render the advocacy of opium superfluous.

Always bearing in mind, then, the evils of delay in cases of strangulated hernia, and the danger of dallying too long with medicines, we may assume that the use of opium in this class of affections is of great importance; and this being granted—what is the best mode of administering it? We require its full sedative effect, and this, as rapidly as possible; and we have usually to contend with a condition of the stomach which causes it to eject everything received into it, before time for absorption has elapsed.

Two years since, when I saw a case of femoral hernia about twelve hours after it had become strangulated, it struck me that, by the subcutaneous injection of morphia, we might obtain the result which the surgeon who had previously seen the case had sought for by the administration of an opiate draught. Instead, therefore, of proceeding to the operation for the division of the stricture, which we were about to perform, so soon as we should have administered chloroform and tried the taxis, we injected almost a grain of muriate of morphia (liq. morph. muriat. π L. P.L., 1851), and left our patient quiet for a few hours.

On our return, we found her free from pain and sickness, the tumour no longer tense; and without any difficulty we succeeded in returning the now reducible hernia. Although we cannot, of course, expect such a happy result in all cases where the full effect of an opiate is obtained, it is something to be able to obtain this effect; and I would, therefore, strongly urge the adoption of this mode of administering opium at once, in cases of strangulated hernia, instead of wasting time in futile efforts to obtain the effect of the remedy by administering it by the mouth. I have used this method now in several cases, where I have seen the patients early, and of course have never failed to induce the physiological effects of the drug, although with one or two only of the cases of strangulated hernia has the result been to render the operation unnecessary.

The method of exhibiting remedies by subcutaneous injection is now pretty generally practised, and the plan which I am in the habit of adopting and which I here recommend, has probably occurred to others of our associates; but in my hands it has so manifestly saved patients from the danger of an operation, that I would impress upon all the duty, when administering opium for obstructed bowels, of adopting this simple and efficacious improvement in practice.

MEDICAL QUALIFICATIONS. The governors of the Stockport Infirmary have adopted the following resolution: "That a degree in medicine of a British university, or the licentiatehip of the Royal College of Physicians of London, or the license of the Apothecaries' Company of London, be accepted by the committee as proof of medical qualification in all cases where the licence of the Apothecaries' Company, London, alone is now required by the rules.

MEDICAL CHARITIES. The magnificent medical charities of our land, established and supported by individual benevolence, are usurping the duties of society at large. Their object is frustrated, and their utility impaired, by the increasing number of paupers who crowd their doors. These come, not less for the food they sometimes obtain, than for the medicines they require, but they come chiefly because they have no confidence in the medical relief provided by the Poor-law, and, least of all, in the treatment received in the workhouse hospital. (*Dr. Stallard.*)

The Medical Council.

REPORT OF PROCEEDINGS, APRIL 1865.

TUESDAY, APRIL 11TH.

G. BURROWS, M.D., President, in the Chair.

Medical Education. The Council resolved itself into a Committee on Education; the President in the chair.

Age for Licence to Practise. Dr. ANDREW WOOD said that the recommendation of last year was—

"That the age of twenty-one be the earliest age at which any professional licence shall be obtained; and that the age shall in all instances be duly certified."

Dr. A. SMITH asked whether there were any means of enforcing the recommendation, as it was sometimes notoriously disregarded.

Dr. ANDREW WOOD said that students were sometimes admitted to final examination before the age of twenty-one. Applications to do this were occasionally made to the Royal College of Surgeons in Edinburgh; but without success. Other boards, however, admitted candidates to examination before being of full age.

Dr. A. SMITH. Some not only do this, but give the diploma.

Mr. SYME moved that the recommendation stand as follows—

"That the age of twenty-one be the earliest age at which a candidate for any professional licence shall be admitted to his final examination; and that the age shall in all instances be duly certified."

Dr. PAGET seconded the motion.

Dr. APJOHN thought it unnecessary to legislate on the subject. The University of Dublin was opposed to the proposal.

Dr. QUAIN said that if a student were admitted to pass an examination at any age, he might do so before his judgment was properly matured.

Mr. SYME remarked that the Council must decide what was useful and necessary, without reference to the licensing bodies.

Dr. STOKES agreed that the Council must do what was useful and necessary; but much injustice might be done by refusing to admit students to examination before the age of twenty-one. There were many who might desire to improve their professional knowledge, after having been set free from the care attending an impending examination.

Dr. ALLEN THOMSON said that there was a great difference in young men, as to their advancement in the studies by which they were prepared for examination and in their practical knowledge. He would allow them the opportunity of being examined at an earlier period, and of then improving themselves in practical knowledge. In the University of Glasgow, the men who passed the examination at the age of twenty were the best prepared. The Council had already determined that the earliest age at which a diploma could be granted should be twenty-one. This was a kind of contract with the public; but the age at which a student should be allowed to pass his final examination was a different matter. He was quite sure that the resolution proposed by Mr. Syme would have an injurious effect.

Mr. ARNOTT supported Mr. Syme's motion. If students complete their curriculum before the age specified, let them follow out the pursuit of professional knowledge at home or abroad before presenting themselves for examination. The age for examination should be fixed at twenty-one; and if any of

the Universities admit candidates at an earlier age, let them do this at their risk.

Dr. PAGET believed it would be for the advantage of students to keep them at their studies if they were ready to pass before the age of twenty-one. It would also be for the good of the public.

Dr. APJOHN moved, as an amendment, the recommendation in the form in which it originally stood in the report of the Committee.

Dr. CORRIGAN seconded the amendment. He looked on Mr. Syme's proposal as likely to become a *casus belli* between the Council and the licensing bodies. The Queen's University in Ireland would not comply with it. He referred to the hardship that would be inflicted in some cases where the examinations took place only at long periods, on candidates who were within a few weeks only of the required age.

Dr. AQUILLA SMITH said that in the King and Queen's College of Physicians the admission of students before the age of twenty-one had proved beneficial in relieving the students from examination. He did not see what harm was done by such admission. Very few availed themselves of the opportunity; and those were the most diligent students.

Dr. ANDREW WOOD suggested as an addition to Mr. Syme's resolution, that exceptional cases might be allowed.

Mr. SYME consented to make the addition suggested; which was accordingly appended to the resolution as follows—

"And that a return of any exceptions to this recommendation allowed by the licensing bodies, together with the reasons for such exceptions, be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted."

Dr. SHARPEY approved of the resolution with the addition suggested.

After some further discussion, in which Dr. STOKES, Dr. A. THOMSON, Dr. ACLAND, Dr. QUAIN, and Dr. CORRIGAN, took part,

The PRESIDENT said that, as he should vote on the question, he would explain his reasons for doing so. Having been for thirty years an examiner and teacher in a medical school, he could quite admit the existence of young men of uncommon talent and great industry, capable of mastering the subjects of examination at an early age. But were the Council to legislate for such exceptional cases, or for students in general? Whatever rules might be laid down, there were some cases in which they would press heavily? If there were to be a time allowed between the examination and the granting of the licence, that time should be fixed. The objection of the incubus of examination had been met by some remarks made by Dr. Paget and Dr. Sharpey. The elementary subjects were removed from the student's mind at an early period; the final examination was practical; and the time remaining to the student who completed his course of study before coming of age would be well spent in the hospital or in studying pathology.

The amendment was then put to the vote and lost; 8 voting for and 14 against it. Mr. Syme's proposal was then carried, by a majority of 14 against 6, in the following form—

"That the age of twenty-one be the earliest age at which a candidate for any professional licence shall be admitted to his final examination; and that the age shall, in all instances, be duly certified; and that a return of any exceptions to this recommendation allowed by the licensing bodies, together with the reasons for such exceptions, be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted."

Professional Study. Dr. ANDREW WOOD moved, and Dr. FLEMING seconded—

"That the first Clause of Section III be adopted; viz., 'That no licence be obtained at an earlier period than after the close of the last winter session of the fourth year of study, after the registration of the candidate as a medical student.'"

Dr. ANDREW WOOD moved as an amendment, and Mr. ARNOTT seconded—

"That no licence be obtained at an earlier period than after the expiration of forty-eight months subsequent to the registration of the candidate as a medical student."

After a discussion in which several members took part, the amendment was carried; and, being put as a substantive motion, was also carried.

Dr. ANDREW WOOD required that the names of the majority and minority be taken down. *Majority*, 12—The President, Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Embleton, Dr. Storrar, Dr. Smith, Mr. Hargrave, Dr. Leet, Dr. Sharpey, Mr. Rumsey. *Minority*, 8—Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Thomson, Dr. Apjohn, Dr. Parkes, Dr. Christison, Dr. Stokes.

Mr. HARGRAVE moved, and Dr. PAGET seconded—

"That Clause 2 of Section III be adopted; viz., 'That the course of study required for a licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a recognised medical school; and that evidence shall be produced that the remaining period of the four years has been passed in the acquisition of professional knowledge.'"

Dr. CORRIGAN said that the Council ought to define what was the meaning of the term "medical school."

Dr. PARKES suggested that the expression should be "at a medical school recognised by the body granting the licence."

Dr. ANDREW WOOD was of the opinion that the words "medical school" should be defined. Some licensing bodies recognised schools which others did not. The Council was not prepared to pass the resolution until the question as to the meaning of a medical school was decided.

Mr. SYME thought a medical school might be defined as an institution in which two or more courses of instruction on medical subjects were given.

Dr. EMBLETON proposed as an amendment, and Dr. ANDREW WOOD seconded—

"That the Committee, before proceeding further, determine what are the requisites for constituting a medical school under their recommendations."

Dr. PARKES did not think it absolutely necessary that a hospital should be attached to a school. He referred to the condition of University College before the erection of its hospital.

The PRESIDENT observed that both University and King's Colleges had large medical schools for several years before hospitals were attached to them.

Dr. ANDREW WOOD said that the medical school of the College of Surgeons in Edinburgh had no hospital attached.

Dr. ACLAND said that a definition had been proposed last year which the observation of Dr. Parkes and the President showed to be improper. In Oxford, during the last fifteen years, great exertions had been made to encourage the study of medical science, for two purposes: first, to improve general education; and secondly, to induce persons to enter the medical profession through the Universities. If the Council adopted a definition of a medical school which should exclude Oxford, it would be of no consequence to the University, but it would be injurious to the medical profession.

Dr. SHARPEY considered that it would be injudicious to attempt to define a medical school.

The PRESIDENT asked whether the Council would

be prepared not to recognise a course of instruction in chemistry given in an institution which was not a medical school.

Dr. ANDREW WOOD thought it an important part of the duties of the Council to define what was meant by a medical school.

After some remarks from Dr. CHRISTISON, Dr. EMBLETON, Dr. AQUILLA SMITH, and Mr. COOPER, the amendment was put to the vote and lost; 3 voting for and 12 against it.

Dr. CHRISTISON then proposed as a second amendment—

"That the course of professional study required for a licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a school recognised by any of the licensing bodies mentioned in Schedule (A) to the Medical Act."

Dr. PARKES seconded the amendment; which, on being put to the vote, was carried by a majority of 15 to 1, and was then carried *nem. con.* as a substantive motion.

On the motion of Dr. PARKES, seconded by Dr. STORRAR, the next clause of the report—proposing that "the regulation of the duration of sessions, and the extent and duration of courses of lectures and instruction, be left for the present to the several licensing bodies"—was omitted.

Mr. SYME proposed, Dr. STORRAR seconded, and it was resolved—

"That Clause 4 of Section III be adopted; viz., 'That it be recommended to the several licensing bodies that the courses of instruction required by them should be framed in such a manner as to secure a due share of attention, both to preparatory branches and to those more strictly connected with the practice of medicine and surgery; and that it be suggested accordingly to these bodies, that their regulations should be such as to prevent attendance upon lectures from interfering with hospital and clinical study.'"

Dr. ALLEN THOMSON moved—

"That Clause 5 of Section III be omitted" (viz., "That, while avoiding for the present all other details by which this object may be attained, it be recommended that no subject of lectures be enforced by regulation to be attended more than once.")

Mr. SYME moved as an amendment that the clause be adopted.

Dr. AQUILLA SMITH seconded the amendment. Compulsory attendance on lectures had been very much complained of.

Dr. EMBLETON and Dr. CORRIGAN supported the original motion.

Dr. APJOHN asked whether practical and general chemistry were to be considered as one course or as distinct.

Mr. HARGRAVE opposed the resolution.

Mr. ARNOTT thought that a single course of some subjects—such as surgery—was not enough.

The amendment was then put to the vote and lost; 6 voting for and 14 against it. The original motion was carried by a majority of 15 to 5.

Dr. STORRAR moved, and Dr. EMBLETON seconded, the adoption of the sixth clause; viz.—

"That the Council will view with approbation any encouragement held out by the licensing bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly professional character."

Dr. APJOHN moved as an amendment, and Dr. CORRIGAN seconded—

"That Clause 6 of the recommendations relating to professional examination be omitted."

Dr. ANDREW WOOD said that the natural sciences

afforded a good mental training for those intending to engage in professional studies. The College of Surgeons of Edinburgh had made them optional in the preliminary examinations, so far as regarded natural history. He would not, however, have chemistry as part of a preliminary examination, lest the students should lose sight of its value in regard to medicine.

Dr. AQUILLA SMITH supported the motion. Students should be encouraged to obtain a knowledge of natural science at an early period.

Dr. CHRISTISON said that students would gain by being allowed to be examined in chemistry before beginning their professional studies. In fact, they would have thus another year of study.

After some further discussion, the amendment was put and lost; the votes being, for 5, against 15.

Dr. ACLAND then proposed as a second amendment, and Mr. RUMSEY seconded—

"That the various licensing bodies be requested to take into their consideration what portions of natural science shall be comprised in the course of general education, prior to the period of strictly professional study."

The amendment was also negatived. The original motion was then put to the vote, and carried.

The Council then resumed.

Erasure of a Name from the Register. A document, declared by the solicitor to be a regular certificate of the conviction, at Castlebar, County Mayo, of John Carter Barrett, of felony, was submitted to the Council.

Dr. A. SMITH moved, Dr. STOKES seconded, and it was resolved—

"That the name of John Carter Barrett be erased from the *Medical Register*."

WEDNESDAY, APRIL 12TH.

G. BURROWS, M.D., President, in the Chair.

The Council, on the motion of Dr. ANDREW WOOD, resolved itself into a General Committee on Education, the President in the chair; and proceeded with the consideration of the Report of the Select Committee.

Professional Education. Dr. STOKES moved—

"That Clause 7 of Section III be omitted; viz., 'That the several licensing bodies be requested to furnish a short statement of the mode in which their examinations are now conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways.'"

He considered that it was unnecessary to be constantly worrying the examining bodies.

Mr. SYME seconded the resolution. The clause was quite unnecessary after the resolution of the Council on the subject of visitation of examinations.

Dr. PARKES moved as an amendment—

"That those licensing bodies which have not already done so, be requested to furnish a statement of the dates of their examinations, and of the modes in which such examinations are conducted, whether by written, oral, or practical examination, and of the length of time a candidate is under examination in each or all of these ways; and that the Registrar transmit these reports to the members of the Council, in order that they may be taken into consideration at the next meeting of the several Branch Councils."

Although the clause in the report did not actually receive the sanction of the Council last year, several of the examining bodies, such as the Royal College of Physicians of London, had already complied with it, and others had stated they would have no objec-

tion to do so. It was extraordinary that the Council had not before required this information from the licensing bodies, which it had the power to do; and, if advisable before, it was necessary now for the purpose of supervision. If the Council had not the statements, the visitors of examinations must either wait for information until they entered the examination-rooms, or derive it from the members of the Council representing the several bodies. Either of these methods would be inefficient, because the Council could not form a judgment on the examinations until the statements regarding each board were before every member. No opposition, he thought, could be logically offered to the proposal, except by the minority who opposed the supervision of examinations; and he could not do these gentlemen the injustice to suppose that they would act in a factious spirit.

Dr. ANDREW WOOD seconded the amendment. He believed Mr. Syme would see that it was right to call for the statements. If there was any function of the Council distinctly marked out in the Medical Act, it was this. Visitation did not supersede the necessity for having the statements referred to, but rendered them even more necessary than before. It was very desirable that each examining body should be acquainted through its representative with the regulations of all others, so that it might amend its own defects or suggest amendments to others.

Mr. SYME said that, if it was considered necessary to have the returns for the purpose of carrying out visitation, he would not oppose the desire of the Council, and withdrew his name as seconder of Dr. Stokes's motion.

Dr. AQUILLA SMITH seconded the original motion.

Dr. APJOHN said that Dr. Parkes's resolution did not oblige the licensing bodies to send in returns each year.

Dr. CORRIGAN said that Dr. Parkes had founded his resolution on the fact that the Council would undertake the visitation of examinations. He would not undertake the task of visitation, which he considered impracticable. All that was required might be done by making the examinations public.

Mr. HARGRAVE said it was absurd to place the superintendence of the examinations in the hands of the Branch Councils. He questioned the impartiality with which the visitations would be conducted; and said that no independent body would submit to them.

Dr. EMBLETON said that, if there was any point on which the examining bodies ought to be "worried", it was that referred to in Clause 7. The Council would be in fault if they did not require the information. The licensing bodies would not refuse it; and the Council should be unanimous in asking for it.

Dr. Parkes's amendment was then put to the vote, and carried; 14 voting for and 4 against it. It was then put as a substantive motion, and carried *nem. con.*

Examinations. Mr. SYME moved—

"That Clause 1 of Section IV be adopted; viz., 'That the licensing boards be advised to encourage the periodical examination of students at the several classes.'"

Dr. PAGER thought the subject one of mere detail.

Dr. ANDREW WOOD seconded the motion. The matter was one of fundamental importance and not of trivial detail. When he was a student, there were no means of instruction but listening to lectures; there were no regular class-examinations. Hence many neglected their studies at first, and were at last obliged to cram for the final examinations. It would be very beneficial if the licensing bodies would demand certificates of attendance on

the class-examinations; a great stimulus would be given to attention on the part of the students, and the lecturers would be enabled to see how far their pupils were profiting by their instruction. By placing its *imprimatur* on class-examinations, the Council would be raising the profession more than any other way.

Dr. AQUILLA SMITH considered that the system of class-examination was carried too far. He did not know how an exact system of carrying out periodical examination could be prescribed.

Dr. SHARPEY said that the resolution implied merely that the Council would encourage class-examinations. Nothing was said as to the periods or the manner in which they should be conducted. He could speak from experience in favour of such examinations. It was difficult to carry out oral examinations thoroughly; but since last year he had tried simple written examinations of about an hour each, to be voluntarily attended; and these he believed to have been very useful.

Mr. COOPER said that the question was one between the teachers and students, and had nothing to do with the Medical Act.

Dr. PAGER explained that he recognised the high value of class-examinations, but that he objected to unnecessary interference with freedom of action.

Dr. CORRIGAN thought that the question should be left to be decided between the lecturers and students. He would vote for the motion if the words "educational bodies" were substituted for "licensing boards."

The PRESIDENT considered the matter an important one; but that it would better be left to the licensing bodies. If the Council laid down certain principles this year, such as registration of students, visitation of examinations, period of study, etc., much would be accomplished. But, if they entered into all details, however important, they would not do several things which ought to be done; and, at the present rate of progress of business, there was work enough on the programme for another fortnight.

Dr. PAGER moved as an amendment, and Dr. ALLEN THOMSON seconded—

"That, while acknowledging the great educational value of the periodical class-examinations of students, the Council decline to issue advice or instructions on the subject."

The amendment was negatived; 6 voting for and 12 against it. The original motion was also lost; 7 voting for and 12 against it.

Dr. ANDREW WOOD required that the names and numbers of the majority and minority and of those who did not vote be taken down. *Majority*, 12—Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Acland, Dr. Paget, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, Dr. Stokes. *Minority*, 7—Dr. Embleton, Dr. Andrew Wood, Dr. Fleming, Mr. Syme, Dr. Sharpey, Dr. Parkes, Dr. Christison. *Did not Vote*, 3—The President, Dr. Storrar, and Dr. Quain.

Mr. HARGRAVE moved, and Dr. STORRAR seconded—

"That Clause 2 of Section IV be omitted."

Dr. ANDREW WOOD moved as an amendment, and Dr. PARKES seconded—

"That Clause 2 stand as at present; viz., 'That the final examinations of the licensing boards be so carried on as to be an efficient test of the practical acquaintance of candidates with the several branches of medical knowledge, and especially with the practice of medicine and surgery.'"

The amendment was negatived; 7 voting for and 11 against it. The original motion was then put to the vote and carried.

Dr. ANDREW WOOD required that the names and

numbers of the majority and minority be taken down. *Majority*, 12—Dr. Acland, Dr. Embleton, Dr. Storrar, Mr. Syme, Dr. Thomson, Dr. A. Smith, Mr. Hargrave, Dr. Leet, Dr. Apjohn, Dr. Corrigan, Dr. Sharpey, Dr. Stokes. *Minority*, 7—Dr. Alderson, Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Andrew Wood, Dr. Fleming, Dr. Parkes.

Dr. FLEMING moved, Mr. ARNOTT seconded, and it was resolved—

“That Clause 3 of the Report be adopted as thus amended: ‘That the professional examination for any licence be divided into two parts; the first embracing the primary or fundamental branches of medicine; and the second the branches directly connected with the practice of medicine and surgery; that the former be not undergone till after the close of the winter session of the second year of professional study; and the latter, or final examination, not till after the close of the prescribed period of professional study.’”

Dr. STORRAR moved, and Dr. SHARPEY seconded—

“That Clause 4 be adopted as thus amended: ‘That examination in physics, chemistry, botany, and natural history may be undergone at an earlier period than the first professional examination.’”

Dr. APJOHN said that a knowledge of chemistry could not be acquired under two years. He suggested the omission of the word chemistry. If students were allowed to pass the examination in chemistry before entering on their studies, they would be liable to neglect it afterwards.

Dr. SHARPEY said that the University of London had a preliminary scientific examination in inorganic chemistry, and also required a further knowledge of chemistry at the first M.B. examination.

Mr. SYME said that students should be examined in chemistry before entering on their regular course of study. But they should not be allowed to neglect it afterwards.

Dr. ANDREW WOOD moved as an amendment the resolution with the omission of the word “chemistry.”

Dr. APJOHN seconded the amendment.

Dr. SHARPEY thought that there should be nothing to prevent an examination in elementary chemistry at an earlier period than the first professional examination.

Dr. PAGET said that the amendment was calculated to discourage the reception of chemistry into general education. Chemistry was now becoming taught in schools; and the number of candidates who presented themselves for examination in chemistry at the Cambridge local examinations was increasing yearly.

Dr. ALLEN THOMSON said that the ordinary courses of chemical lectures which medical students were required to attend contained much which had no direct bearing on their professional studies; hence he would desire to have the elementary parts of chemistry taught before the commencement of medical study.

Dr. CHRISTISON denied that the examination of students in chemistry at an early period involved the subsequent neglect of this science. Examiners in *materia medica*, medical jurisprudence, and medicine, could all examine candidates in medical chemistry. This was done in Edinburgh.

Dr. ACLAND would object to preventing students from passing an early examination in elementary chemistry if they had the requisite knowledge.

After some remarks from Dr. ANDREW WOOD, Mr. COOPER, and Dr. CORRIGAN, Dr. Andrew Wood's amendment was carried by a majority of 11 to 7. It was then put as a substantive motion: whereon

Dr. THOMSON moved as a second amendment and Dr. PAGET seconded—

“That Clause 4 be amended as follows: ‘That

examination in physics, the elements of chemistry, and in botany and natural history, may be undergone at an earlier period than the first professional examination.’”

This amendment was negatived.

Dr. A. Wood's amendment was then, as a substantive motion, put to the vote, and carried.

The Council now resumed.

Report of the Committee on the Subjects of General Education. Dr. STOKES presented the following

REPORT.

The Committee on the Subjects of General Education having duly considered the subject remitted to them, resolve to recommend to the Council—

That after the year 1867, the examinations in subjects of general education be left entirely to the national educational bodies recognised by the Medical Council—the Council confining its regulations on general education to publishing a list of the examinations which may from time to time be approved of by them, it being understood that no certificate which does not affirm the proficiency of the candidate in Latin, and also his knowledge of the elements of geometry, and of the elements of mechanics and hydrostatics, be accepted.

W. STOKES, *Chairman*.

On the motion of Dr. PARKES, seconded by Dr. PAGET, the Report was ordered to be received, and entered on the Minutes. (See page 405.)

Report of the Committee on Amendment of the Medical Acts. Dr. ANDREW WOOD brought up the following

REPORT.

The Committee beg to report that they have not only carefully considered the proposed amendments of Clauses in the Medical Act, which were specially referred to them by the Council, but have also deemed it their duty to take into consideration all the important Clauses of that Act. They have had during their sittings the advantage of the presence and advice of the solicitor of the Council, Mr. Onvry, who has prepared, in accordance with the resolutions of the Committee, the Draft of an Amended Bill, which the Committee now beg to bring before the Council.

Draft of Bill to Amend the Medical Act of 1858.

Whereas the Medical Act 1858 has been found ineffectual to enable persons requiring medical aid to ascertain who are qualified practitioners, and it is desirable to amend the said Act in several respects.

Be it therefore enacted by the Queen's Most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons in the present Parliament assembled and by the authority of the same as follows:—

1. This Act may for all purposes be cited as “The Medical Acts Amendment Act, 1865.”

2. This Act shall take effect from the passing thereof.

3. The following sections of the Medical Act 1858, shall be and the same are hereby repealed, viz.: Section xiv and Section xl, but without prejudice to any proceedings which may be pending under such sections or any of them.

In lieu of Section xiv. 4. It shall be the duty of the Registrars to keep their respective registers correct, in accordance with the provisions of this Act, and the orders and regulations of the General Council, and to erase the names of all registered persons who shall have died, or who, having ceased to practise, shall desire to have their names removed from the register, and from time to time to register all alterations in the addresses or qualifications of the persons registered under the Medical Act, 1858.

The Registrars, in these respects, may act upon such evidence as may appear to them sufficient, subject to any rules or regulations which the General Council may make thereon. [And for the purposes aforesaid, the Registrar may write a letter to any registered medical practitioner, addressed to him according to his registered address, to inquire whether he has ceased to practise, or has changed his residence; and if the answer to such letter be that the person has ceased to practise and desires his name to be removed from the register, or if no answer be returned to such letter within the period of six months from the sending of the letter, it shall be lawful to erase the name of such person from the register.] (For this paragraph the following was substituted when the report was discussed by the Council.) [And for the purposes aforesaid the Registrar may write a letter to any registered medical practitioner, addressed to him according to his registered address, to inquire whether he has ceased to practise, or has changed his residence; and if the answer to such letter be that the person has ceased to practise and desires his name to be removed from the register, it shall be lawful to erase the name of such person from the register; but if no answer be returned to such letter within three months, the Registrar shall then write a second letter, making similar inquiries; and if no answer be returned to such letter within three months thereafter, it shall be lawful to erase the name of such person from the register.] Provided always that any name which may be erased by the Registrars may be restored by the direction of the General Council. No person whose name has been erased from the register by order of the General Council, or any Branch Council, shall be re-registered, either on the original or any new qualification, except by the direction of the General Council or Branch Council, as the case may be.

In lieu of Section XL. 5. Any person practising medicine or surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule (A) to this Act, or that of physician, surgeon, doctor, professor of medicine, professor of surgery, or any other title, name or designation used by or used to distinguish duly qualified practitioners in medicine or surgery, shall upon a summary conviction, be liable to a penalty not exceeding £20 for each offence.

6. The words "qualified to be" in the seventh section of the Medical Act, 1858, shall be and the same are hereby repealed.

[In lieu of Section XLVIII.] 7. It shall, notwithstanding anything in the Medical Act, 1858, contained, be lawful for Her Majesty, by Charter, to grant to the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, and the Faculty of Physicians and Surgeons of Glasgow, or any or either of them power to institute and hold examinations for the purpose of testing the fitness of persons to practise as Dentists who may be desirous of being so examined, and to grant certificates of such fitness.*]

The Committee call attention to the changes in the present Medical Act, which are proposed in the Draft Amended Bill:

1. *The Preamble.* The preamble to the Act as it at present stands, says:

"Whereas, it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners."

The proposed preamble of the amended Bill is to this effect:

"Whereas, the Medical Act of 1858 has been found ineffectual to enable persons requiring medical aid to ascertain who are qualified practitioners."

2. SECTION VII. This section as it at present stands is this:

"Members of the General Council representing the Medical Corporations must be qualified to be registered under this Act."

It is proposed that they shall be henceforth not "qualified to register," but actually "registered." This alteration is in consonance with the clause proposed to supersede Clause 40, which amended clause makes registration compulsory on all qualified practitioners engaged in the practice of their profession.

3. SECTION XIV. This section as it at present stands is as follows:

"It shall be the duty of the Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the orders and regulations of the General Council, and to erase the names of all registered persons who shall have died, and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under this Act; and to enable the respective Registrars duly to fulfil the duties imposed upon them, it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter, it shall be lawful to erase the name of such person from the Register; provided always, that the same may be restored by direction of the General Council, should they think fit to make an order to that effect."

The amended clause stands thus (see preceding Draft, Section 4).

The object of the amendment of this clause is to facilitate the duty of the Registrars in keeping their Registers correct; to enable persons who, having ceased to practise, may desire it; to have their names erased from the Register; to render it imperative on the Registrar to address to any Registered Medical Practitioner (instead of one letter within six months, as in the Act as at present) two letters within six months, at an interval of three months, inquiring as to change of residence before erasing his name from the Register;* and to prevent any person who has been once erased from the Register from being re-registered without the instructions of the General or Branch Councils.

3. SECTION XL. As it at present stands is as follows:

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner, or Apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law, as a Physician or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an Apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

The clause proposed to replace this section, as agreed upon by the Medical Council, is as follows (see preceding Draft, Section 5).

In reference to this subject, it may be remarked that the object of the Medical Act was to enable "persons requiring medical aid to distinguish qualified from unqualified practitioners." But the offence for which a penalty was instituted under Section XL of that Act was the falsely pretending to be regis-

* This clause was not adopted by the Council.

* These words were introduced in Council.

tered under the Act. In the working of that section it has been found that it has failed to enable the public to distinguish qualified from unqualified practitioners, seeing that it has not proved efficient to prevent persons from practising medicine and surgery under titles falsely assumed, and thus the public have been deceived and imposed upon, to the injury of their health and danger to their lives.

[4. SECTION XLVIII stands at present thus:

"It shall, notwithstanding anything herein contained, be lawful for Her Majesty, by Charter, to grant to the Royal College of Surgeons of England power to institute and hold examinations for the purpose of testing the fitness of persons to practise as Dentists who may be desirous of being so examined, and to grant certificates of such fitness."

The proposed clause stands thus (see Draft, Section 7).

The Committee have thought it right to extend the operation of Section XLVIII of the Medical Act, so as to enable Her Majesty to grant charters to the Scotch and Irish Surgical Bodies, authorising them to grant certificates to Dentists.*]

In reference to the various questions specially referred to them by the Council, the Committee have to report:

1. In reference to the amending of Sections xv and xxxi, with the view of securing that all persons to be placed on the Register should have been duly educated, tested and qualified in all branches of the profession, whether medical or surgical, the Committee are of opinion that it is highly desirable that every medical practitioner should have a complete or double qualification. They see difficulties, however, in the way, for the present, of framing compulsory clauses which would secure that important object. They would, however, point out that by Section xix of the Medical Act, which is a permissory section, powers have been provided by which any two or more of the licensing bodies may unite and co-operate in conducting examinations required for qualifications to be registered under the Act. [Were this course carried out in London and in Dublin as it has already been successfully carried out in Scotland, the Committee believe that in this way, without the necessity of compulsory legislation, the great object would be effected of combining and concentrating the licensing bodies, to the relief of the student, and the advantage of the profession and the public.†]

2. SECTION XVIII at present stands thus:

"The several colleges and bodies in the United Kingdom, mentioned in Schedule (A) to this Act, shall, from time to time, when required by the General Council, furnish such Council with such information as they may require, as to the course of study and examinations to be gone through in order to obtain the respective qualifications mentioned in Schedule (A) to this Act, and the ages at which such courses of study and examination are required to be gone through, and such qualifications are conferred, and generally, as to the requisites for obtaining such qualifications; and any member or members of the General Council, or any person or persons deputed for this purpose by such Council, or by any Branch Council, may attend and be present at such examinations."

It has been proposed to amend the section by adding to it the following word or words to the same effect, viz.:

"And may also inspect the written answers of the candidates, and report concerning the examinations

and answers to the General Council; and to the persons deputed by the General Council as aforesaid, in such number as may be determined by the General Council, with the approval of one of Her Majesty's principal Secretaries of State, there shall be paid such fees for services and such reasonable travelling expenses as shall from time to time be allowed by the General Council and approved by the Commissioners of Her Majesty's Treasury; and the said payments shall be made out of the residue of the monies annually received for carrying this Act into execution, after defraying the expenses of the General Council and the Branch Councils, and, if necessary, out of further monies to be provided for the said purpose by vote of Parliament."

The Committee do not consider this amendment either necessary or expedient. The Branch Councils have the power under the Act as at present to visit the examinations of the licensing bodies, or to depute any person or persons to do so; they have also the power, as the Committee are advised by Mr. Ouvry, to remunerate the visitors of the examinations from the funds contributed under the Act. The Committee consider that it would be inexpedient to go to Parliament to ask a supplementary money grant for the purpose. They trust that ere long the expense of the meetings of the Council will be diminished, and that there will be sufficient funds to meet the expenses of visitation in any form that may be deemed necessary.

3. The Committee, after considering the penal sections of the Act, do not recommend that application should be made to Parliament for stronger powers to be given to magistrates administering the Act, or for higher penalties. The Committee believe that, if the clause proposed in lieu of Section xl prove effective, the present powers and penalties will be found adequate.

4. In regard to the question of the Registration of Licentiates in Dental Surgery, the Committee having given that consideration to the memorial of the dental surgeons to which it is justly entitled, are of opinion that it is inexpedient to place upon the *Medical Register* dental practitioners not otherwise qualified; holding as they do that that would constitute a further obstacle, in addition to those at present existing, to the securing that all persons whose names shall be inserted in the *Medical Register* shall be fully qualified to practise all branches of their profession.

The Committee have, in conclusion, to suggest the following form of memorial, to be addressed by the President, in the name of the Council, to the Secretary of State for the Home Department; viz.:

General Medical Council, April 1865.

SIR,—I am requested by the General Medical Council respectfully to solicit your attention to certain points on which it has been found, by experience, that the working of the Medical Act, 1858, has not been satisfactory; and to ask you to introduce a Bill in the present session for the amendment of that Act.

In order to place the matter before you in a practical form, the Council has caused a draft Bill to amend the Medical Act to be prepared, and such draft is transmitted herewith.

The only amendment to which I need direct your special attention, as involving an important change, is that which affects the fortieth section of the Act of 1858. It has been found, in practice, almost impossible to establish the false pretence, which is the offence punishable under that section; and accordingly ignorant pretenders, possessing no legal qualification to practise, and, assuming falsely medical and surgical

* The paragraphs here enclosed within brackets were not adopted by the Council.

† This sentence was not adopted by the Council.

titles, with impunity deceive the public, prey upon their credulity, and endanger their lives.

The most effectual remedy for this state of things would be the absolute prohibition of practice by persons not possessing the qualifications mentioned in the Act of 1858; but, as the Council considers that there might be difficulty in inducing Parliament to adopt so stringent a rule, the Council has framed a clause which it is hoped may meet the evil which the present existing Act has been found inadequate to suppress.

The other suggested amendments do not require separate remark; but I am to ask that you will be good enough to receive a deputation from the Council, when the reasons on which the proposed amendments rest will be fully stated to you.

As it is earnestly wished that the proposed Act should pass this session, I am to urge that you will be pleased to appoint a time for receiving the proposed deputation at your earliest convenience.

I have the honour to be, sir,

Your most obedient servant,

GEORGE BURROWS, M.D., *President.*

The Right Hon. Sir Geo. Grey, Bart., G.C.B., M.P.,

Secretary of State for the Home Department.

ANDREW WOOD, *Chairman.*

Dr. ANDREW WOOD moved, Mr. HARGRAVE seconded, and it was resolved—

“That the Report of the Committee on Amendment of the Medical Acts be received, and entered on the Minutes.”

The Council again resolved itself into a General Committee on Education, the President in the Chair; and resumed the consideration of the Report of the Select Committee.

Professional Examinations. Dr. CORRIGAN moved, and Dr. SHARPEY seconded—

“That Clause 5 of Section iv be adopted: viz.: ‘That the professional examinations be conducted both in writing and orally; and that they be practical in all branches in which they admit of being so.’”

Dr. STORRAR moved as an amendment, and Dr. A. SMITH seconded—

“That Clause 5 be adopted, with the addition of the following words; viz., ‘and that, with the view of promoting the adequacy of professional examinations, the final *viva voce* examinations be public, so far as admitting the graduates or licentiates of the examining body.’”

The amendment was negatived. The original motion was then put to the vote, and carried.

Dr. STORRAR moved, Dr. PARKES seconded, and it was agreed—

“That Clause 6 be adopted; viz.: ‘That the professional examinations be held by the several licensing bodies, except in special cases, at stated periods, to be publicly notified.’”

Dr. STORRAR moved, Dr. SHARPEY seconded, and it was resolved—

“That Clause 7 be adopted; viz.: ‘That returns from the licensing bodies in Schedule (A) be made annually, on the 1st of January, and in the subjoined form, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second examinations, and the number of those who have been rejected at the first and second examinations respectively; and that the Registrar forward a sufficient number of forms, with a notice for their being returned, in due time.’”

(A form of return was appended to this resolution.)

The Council now resumed, and adjourned.

THURSDAY, APRIL 13TH.

GEORGE BURROWS, M.D., President, in the Chair.

Amendment of the Medical Acts. Dr. ANDREW WOOD moved—

“That the Report of the Medical Acts Amendment Committee be adopted.”

The Council had already decided against making any changes in Sections xx and xxxi of the Act; and, on Section xl, the Council had agreed on an alteration, which was engrafted into the Report. He proceeded to explain the action of the Committee in reference to several questions referred to them. As to Sections xv and xxxi, the Council might remember that in Mr. Headlam's Bill it was made compulsory on the licensing bodies to combine in the examination of candidates for admission as general practitioners. He regretted that this proposal did not become law. At present, practitioners were entitled to practise according to their qualification or qualifications; and hence, by Section xxxiv, many were placed on the *Register* who had qualification in medicine only, or in surgery only. The Council had expressed an opinion that it was desirable that no one should be registered unless doubly qualified. It was, however, difficult to introduce a clause which should effect this, unless by disfranchising the Colleges of Surgeons and the Apothecaries' Company; and such an attempt would raise the powerful and most probably successful opposition of these bodies. It was thought, therefore, that the Council should express a very strong opinion in favour of the co-operation of the licensing bodies for the purpose of examination. If this course were followed, the necessity for compulsory legislation would be removed. With regard to the proposed addition to Section xviii, the Committee had found, on consultation with Mr. Ouvry, that the Council had already full power of visiting the examinations personally or by deputy, and of remunerating the visitors. He believed that Dr. Sharpey, who proposed the addition, had become convinced of this. Moreover, an application to Parliament for a money grant would be an obstacle to the passing of a Bill; and it was also unnecessary, as the funds of the Council were sufficient for carrying out its objects. The expenditure which had hitherto been unavoidable would be diminished as the work to be done at the meetings of the Council was reduced. The Committee did not think it advisable to apply for increased powers to be given to magistrates, or for higher penalties. The adoption of the amendment of Section xl would be sufficient. As to the registration of the licentiates in dental surgery, the memorial from these gentlemen was expressed in respectful terms, their claims were ably argued, and their case was fairly set forward from their point of view. But it was an objection to their requirement, that the introduction of mere dental licentiates into the *Register* would render them liable to be regarded as medical practitioners. It would be worth the consideration of the dental surgeons whether they should not have a register of their own. Dr. Andrew Wood then explained briefly the amendments proposed in the Draft Bill.

Dr. EMBLETON seconded the motion.

Dr. CORRIGAN proposed as an amendment—

“That the consideration of the Report on the proposed Amendments of the Medical Acts be postponed to the next meeting of this Council, inasmuch as the resolution of this Council of May 4, 1864, directed the attention of the Branch Councils only to Clauses xx, xxxi, and xl, while in the amended Bill now proposed for adoption amendments are introduced which have never previously come under the consideration of this Council, and no opportunity is af-

forded to the several licensing bodies to take these amendments into consideration."

He believed that there never was a greater delusion than to suppose it possible to pass the Bill in this session of Parliament. Many of the licensing bodies would apply for amendments; and the opposition of one alone would stop the progress of the Bill. He referred to the proceedings which took place in the Council last year in regard to the question; and said that, although he had been an indefatigable labourer in the cause, he could not support the present resolution. It was agreed last year that the amendments of the Acts should be confined to three clauses, and that an early meeting of the Council should be held for the purpose of considering them. He objected especially to the proposal to allow the Colleges of Surgeons in Scotland and Ireland to admit licentiates in dental surgery, unless the same privilege were granted to the Colleges of Physicians and to the Universities.

Dr. A. SMITH seconded the amendment, which, on being put to the vote, was lost; 3 voting for and 13 against it.

Dr. QUAIN then moved as a second amendment, and Dr. APJOHN seconded—

"That the Report of the Committee on the Medical Acts Amendment be considered clause by clause, except such clauses as have been already decided on by the Council."

The amendment was carried.

The preamble of the Draft Bill, and Clauses 1, 2, and 3, were put to the vote, and adopted without discussion.

When Clause 4 was put to the vote, the PRESIDENT called attention to the hardship which might be inflicted on a practitioner prevented by illness or other causes from replying to the Registrar. He thought it would be very arbitrary to erase a name in consequence of an answer not being returned to a single letter.

Dr. QUAIN proposed, and Mr. HARGRAVE seconded, an amendment to the effect that the Registrar should write twice, at intervals of three months. (See Clause 4, page 399, col. 1.) The Council agreed to the amendment.

Clause 5, having been already agreed on by the Council, was not discussed. Clause 6 was adopted; and Clause 7 was withdrawn.

The remaining portion of the Report was adopted, with the omissions and amendments already referred to.

Dr. CORRIGAN moved—

"That it would be desirable to have a clause inserted in the amended Bill, or in any Pharmacy Bill introduced to the legislature, rendering it imperative on the apothecaries and compounding chemists of the United Kingdom to follow, in compounding prescriptions, the formularies of the *British Pharmacopœia*, unless otherwise specially directed by the prescriber, inasmuch as compounding indifferently from the formularies of four different Pharmacopœias is dangerous to the lives of the community."

He believed that some of the leading members of the College of Physicians in London had recommended that the old *Pharmacopœia* should be followed; and his impression was that the public had hence been led to regard the *British Pharmacopœia* as of no importance. At present, in each division of the kingdom, both the new *Pharmacopœia* and the old ones of the respective Colleges were in operation; and the preparations bearing the same name in the different works were of such various strength that the minimum dose according to one *Pharmacopœia* would be poisonous according to another. He cited

tincture of aconite as an example. If a case of poisoning occurred, there was no obligation on druggists to follow the formulæ of the *British Pharmacopœia*. The Council should clear themselves from any charge of neglect or carelessness of the lives of the public; but he would not press for a penalty against druggists for not dispensing according to the new *Pharmacopœia*, since the not following the directions of an Act of Parliament in itself constituted a misdemeanour.

Dr. APJOHN seconded the motion.

Dr. LEET said that many of the apothecaries of Ireland, though very particular, followed the old formularies.

Dr. A. SMITH said that, from inquiries he had made in Dublin, he had reason to believe that not more than a thousand copies of the *British Pharmacopœia* had been sold in Ireland.

Dr. CHRISTISON did not think it necessary to ask for fresh powers to enforce the use of the *Pharmacopœia*. In Scotland, he believed that all the druggists understood that they were bound to use the *British Pharmacopœia*; and, as far as he had been able to learn, the practice was very similar in London. Those practitioners who did not follow the *British Pharmacopœia* marked their prescriptions to be dispensed according to the *London Pharmacopœia*. He thought that the *British Pharmacopœia* was gaining ground. It was adopted by practitioners, except by those few whose inclination was to resist.

After some remarks from Dr. ALDERSON, Dr. QUAIN, Mr. COOPER, and Dr. CORRIGAN, the motion was put to the vote, and carried *nem. con.*

Dr. CORRIGAN moved, Dr. ANDREW WOOD seconded, and it was resolved—

"That a copy of the foregoing resolution be forwarded to the Secretary of State for the Home Department."

Dr. ANDREW WOOD moved, Dr. ACLAND seconded, and it was resolved—

"That the memorial contained in the Report of the Medical Acts Amendment Committee to be addressed by the President to the Home Secretary be adopted, and transmitted without delay."

Dr. ANDREW WOOD moved, Dr. FLEMING seconded, and it was agreed—

"That the Report of the Medical Acts Amendment Committee, as now adjusted by the Council, be printed and inserted on the minutes."

It was moved by Dr. QUAIN, seconded by Mr. HARGRAVE, and agreed to—

"That a deputation be appointed to wait on Mr. Waddington, the Under Secretary of State for the Home Department, on Saturday, 15th inst., at one o'clock, according to appointment; the deputation to consist of the President, Mr. Arnott, Dr. Andrew Wood, and Dr. Stokes."

Practice by Chemists and Druggists. Dr. STOKES moved, Dr. ACLAND seconded, and it was resolved—

"That the Report of the Committee on Medical and Surgical Practice by Chemists and Druggists, and on the Pharmacy Bills, be accepted as read, and entered on the minutes."

[We will give the Report in the form in which it was finally adopted. See page 406.]

Report of the Finance Committee. Dr. SHARPEY moved, Dr. A. SMITH seconded, and it was resolved—

"That the Report of the Finance Committee be received and entered on the minutes."

REPORT.

The Finance Committee beg leave to present, in the table subjoined, a Statement of the Estimated

expresses the number of those who passed a preliminary examination before commencing professional study.

ENGLAND.

Royal College of Physicians, London, 142. One exempted by special commission of the College, having being examined at Bedford School in 1859. Total, 143.

Royal College of Surgeons of England, 366. 56 exempted, as they had begun professional study before October 1, 1861. Total, 422.

Apothecaries' Society of London, 331. 37 exempted, having begun professional study before January 1, 1860; 10 ditto, having begun apprenticeship before Jan. 1, 1860 (2 of these passed preliminary examination in January 1865). Total, 378.

University of Oxford. No return.

University of Cambridge, 12.

University of Durham, 55.

University of London, 50.

SCOTLAND.

No returns received from any of the Universities or licensing bodies in this division of the kingdom.

IRELAND.

King and Queen's College of Physicians, Ireland; Royal College of Surgeons, Ireland; Apothecaries' Hall, Ireland; University of Dublin; and Queen's University, Ireland. Total number who had passed preliminary examination, 254. One exempted, having been placed on the Register by special resolution of the Royal College of Surgeons, Ireland. Total, 255.

The Recommendations on Education. Dr. EMBLETON proposed, Mr. COOPER seconded, and it was resolved—

“That a Committee be appointed to arrange and digest the Recommendations on Education of the Council as to the preliminary and professional education and examination, agreed to during the past and present session; and that the Committee consist of Dr. Embleton (chairman), Mr. Cooper, Dr. Leet, Dr. Apjohn, Dr. Stokes, and Dr. Alderson.”

The following day being Good Friday, the Council adjourned to Saturday.

SATURDAY, APRIL 15TH.

G. BURROWS, M.D., President, in the Chair.

The Deputation on the Medical Acts Amendment Bill. The President informed the Council that the deputation appointed at the last meeting of the Council had waited upon the Under Secretary of State for the Home Department, and found that he had given his close attention to the report adopted by the Council on the amendment of the Medical Acts, including the Draft Bill; and, after some further explanations, he promised to forward immediately the report, with the memorial signed by the President, to the Secretary of State, Sir George Grey.

Degrees in Surgery. Dr. STORRAR moved—

“That Section x in Schedule (A) of the Medical Act, be amended by the introduction of the words ‘or Bachelor,’ after the word ‘Master,’ in the first line.”

He explained that, on the passing of the Medical Act, it was found that, in Section xxxi the qualification to practise medicine was understood in its limited sense: and hence several Universities have instituted degrees in Surgery, so as to give their graduates a double qualification. The University of London had thus instituted two degrees, those of Master and of Bachelor of Surgery, to correspond with the degrees of M.D. and M.B. This was not done for the sake of competition with the College of Surgeons, but because it was felt that, so long as the University could

not give academic distinctions in Surgery, the surgical claims of its graduates were not fairly represented. He did not include the University of London alone in his proposal, but was desirous that all the Universities which gave degrees in Surgery should have the privilege of registering them.

Mr. SYME seconded the motion. He had always considered that the degree of Doctor of Medicine should confer the right of practising surgery as well as medicine: and he regretted that a different decision had been arrived at. But this being the case, the recognition of the surgical degree was absolutely necessary.

Mr. ARNOTT objected to the extension of the privilege to all the Universities, on the ground of the difference of constitution between the University of London and the Scotch Universities: the former being an examining body only, the latter both teaching and examining bodies. It would be discouraging to the great medical schools in London to give the Scotch Universities the privilege of granting degrees in Surgery: it would encourage students to desert the London schools and go to Scotland. If the University of London wished for a recognition of their degree in Surgery, let them obtain it by a special charter or Act; but do not let the privilege be extended to institutions which are medical schools. It had been said that the Royal College of Surgeons did not give a medical qualification; but he argued that their examination was medical as well as surgical. Candidates were examined on fever arising from surgical injuries, on inflammation of the brain, lungs, peritoneum, etc. He believed that the College of Surgeons would resist the proposal to recognise the surgical degrees of the Universities, if the motion were carried.

Mr. HARGRAVE considered the requirements of the University of London as to surgery very superficial and meagre.

Dr. QUAIN said that, from its institution, the University of London had examined candidates for the M.B. degree in Surgery as well as in Medicine. But, as a graduate, he had felt it hard that his surgical qualification was not recognised. When the Medical Act was passed, the University Convocation decided in favour of the recognition of degrees in surgery. The Senate also was willing to agree to this, but it was found that the degree of Master of Surgery was alone recognised by the Medical Act. The University had instituted two degrees in Surgery, those of Master and Bachelor; and all that they asked was, that their graduates should be allowed to register these titles. It was desired in instituting the degrees, that all candidates should be required to take the M.B. degree, and after this proceed either to the M.D. degree or to a degree in Surgery according to their inclination.

Dr. A. SMITH said that the Council should decline to give any opinion on the subject. The University of London, if it wanted its surgical degrees to be recognised, should apply to Parliament.

Dr. CHRISTISON said that it was a mistake to suppose that the resolution was intended to confer the power of granting degrees in Surgery on Universities which did not already possess it. Such a power could only be granted by charter to each University. The University of London had this right by charter; and all that was to be decided was, whether its graduates should be allowed to register their surgical degrees. Mr. Arnott was right in saying that the Scotch Universities did not now grant degrees in Surgery; but he was wrong in supposing that they did not possess the power to do so. Their old charters, still in force, entitled them to grant degrees in Medicine, etc., “aut in quavis aliâ licitâ facultate.” He was,

however, by no means desirous that they should exercise this privilege.

Mr. COOPER said that the Society of Apothecaries had done its duty in endeavouring to render practitioners duly qualified. If the College of Surgeons and the Hall were efficient for the licensing of general practitioners, he did not see the necessity for the Council taking measures to form a higher class of these.

Dr. PAGET said that Dr. Storrar's proposal was that the privilege of registering a lower degree in Surgery should be granted to bodies which already could register a higher degree. He feared that if many took the degree of Bachelor in Surgery, a competition would be instituted between that degree and the membership of the College of Surgeons; and competition between licensing bodies was not beneficial to the public.

Dr. CORRIGAN regarded the question as a battle between shops. The Council had set out with the desire of diminishing the number of professional licenses; and now a proposal was made to increase them. The Colleges of Surgeons had obtained their powers on the supposition that the Universities neglected Surgery.

Dr. ACLAND objected to the opening remarks of Dr. Corrigan. As to the University of Oxford, there were no fewer than fifty-two different titles which the University could grant; among these was a license in Surgery, which, in his opinion, was well left in abeyance at least for a time. The question of the recognition of the surgical degrees had not been raised in Oxford because he did not think it expedient to add another to their degrees; but if another University was inclined to act differently, it was unfair and unbecoming to represent the question as a mere battle of petty interests.

Dr. STORRAR having replied, the motion was put to the vote and lost.

Dr. CORRIGAN required that the names and numbers of the majority and minority, and of those who did not vote, should be taken down. *Majority*, 9—Mr. Arnott, Mr. Cooper, Dr. Paget, Dr. Andrew Wood, Dr. Fleming, Dr. A. Smith, Mr. Hargrave, Dr. Apjohn, Dr. Corrigan. *Minority*, 6—Dr. Storrar, Mr. Syme, Dr. Sharpey, Dr. Quain, Dr. Christison, Dr. Stokes. *Did not Vote*, 5—The President, Dr. Alderson, Dr. Acland, Dr. Embleton, Dr. Leet.

The British Pharmacopæia. The Report of the *Pharmacopæia* Committee was taken into consideration. (See page 376.)

Dr. QUAIN moved—

"That the Report of the *Pharmacopæia* Committee be adopted."

The principal changes in the second edition would be that the chemical processes for the preparation of medicines would be omitted; and that the work would be printed in one size only.

Dr. APJOHN seconded the motion.

In answer to a question from Dr. ANDREW WOOD,

Dr. QUAIN said that it was intended to publish the new edition as soon as possible after the next meeting of the Council. There would not be a posological table, but the doses would be mentioned under each medicine; and all alterations from the nomenclature of the other *Pharmacopæias* would be entered.

Dr. CHRISTISON, in the course of the discussion which followed, said that no article would be omitted that was known to be used by medical men; and new preparations used by practitioners in extensive practice would be introduced. The *Pharmacopæia* Committee had thought it better rather to add superfluous matter than to strike out.

The motion was carried.

Dr. CORRIGAN moved, Dr. ANDREW WOOD seconded, and it was resolved—

"That it is desirable to have a proof copy of the new *Pharmacopæia* in the hands of the members of the General Medical Council at least one month before the meeting of the General Medical Council, at which the opinion of the Medical Council is to be given relative to its being published, in order to afford to each member of Council the opportunity of making such suggestions to the Committee as may appear desirable."

Dr. QUAIN moved, Mr. HARGRAVE seconded, and it was agreed—

"That the Executive Committee be authorised to obtain estimates, and make contracts for printing and binding the new edition of the *Pharmacopæia*, when the same is ready for the press."

Dr. QUAIN moved, Mr. COOPER seconded, and it was resolved—

"That the sum ordered to be placed at the disposal of the *Pharmacopæia* Committee, by resolution of May 7th, 1864, be extended from £100 to £300."

Subjects of General Education. Dr. STOKES moved—

"That the first part of the Report of the Committee on the Subjects of General Education, extending to the words, 'approved by them,' be adopted." (See page 395.)

He said that the examination in the subjects of general education was most efficiently conducted by those who were also the teachers of these subjects. In examining by the professional bodies, great abuses had prevailed. He had heard of an instance in which the Registrar of an institution had informed the candidates in what parts of certain works they would be examined; and of another in which one passage was so constantly used, that the book if thrown up would always fall open at that one page. It was true that these events occurred many years ago, and great credit was due to the Colleges of Physicians and Surgeons for instituting a better state of things; but still there was room for improvement. He considered that the want of a good general education was the cause of the low social position of the medical profession. The public should understand that the Council would not be satisfied with a low standard, and that it was their opinion that students should continue to cultivate general studies even after having passed their examinations. He cited the late Sir Benjamin Brodie as supporting this opinion. The Council should insist on a few subjects and take care that they were well known.

Dr. PAGER seconded the resolution. All that was desired was, that medical students should have a fair general examination.

Dr. ANDREW WOOD was not prepared to discuss so important a subject at so late a period of the session. He believed the examination in arts of the College of Surgeons was as good as that of the universities; and the incorporations were not at present in a condition to part with their right of holding the preliminary examinations. The College of Surgeons of Edinburgh had their examination in mathematics conducted by Professor Kelland; but in Latin they found a member of their own profession quite competent. He did not think that the Council would be content with the standard laid down in the report. He moved as an amendment—

"That, as at this late period of the session it is impossible duly to consider the important questions brought forward in the Report of the Committee on General Education, the consideration of that report be delayed till next session."

Dr. FLEMING seconded the amendment.

After a discussion, in which Dr. CORRIGAN, Mr. HARGRAVE, Dr. STORRAR, Dr. APJOHN, Mr. COOPER,

and Dr. STOKES took part, the amendment was put to the vote and carried; the numbers being, for, 11, against, 8. It was then also carried as a substantive motion.

A proposal for the suspension of the standing orders, so as to allow the Council to sit for an additional hour, was negatived by a majority of 12 to 6.

Professional Education and Examination. Dr. EMBLETON moved, Dr. LEET seconded, and it was resolved—

“That the Report of the Committee appointed to arrange and digest the recommendations as to education and examination agreed on during the present session by the General Committee on Education be received, and entered on the Minutes.”

Executive Committee. A ballot was taken for the election of four members to form, with the President, the Executive Committee; and Dr. Acland, Mr. Arnott, Dr. Paget, and Dr. Sharpey, were declared elected.

MONDAY, APRIL 17TH.

GEORGE BURROWS, M.D., President, in the Chair.

The Pharmacy Bill. The Report of the Committee on Medical and Surgical Practice by Chemists and Druggists and on the Pharmacy Bills, was discussed, clause by clause, and finally adopted in the following form.

REPORT.

The Committee appointed on April 7th, 1865, to report whether the Medical Council is charged under the Medical Act with any duty in relation to medical and surgical practice by chemists and druggists, and also to consider and report on the two Bills relating to Pharmacy now before Parliament, report as follows:

In 1864, the General Medical Council represented to Her Majesty's Government the necessity of regulating by statute the practice of pharmacy by chemists and druggists throughout the kingdom. The Committee are of opinion that this necessity continues as cogent as ever; and that the Council ought to encourage and support any approved measure for effecting such legislation.

Two Bills for the purpose have been introduced into the House of Commons during the present session, one promoted by the Pharmaceutical Society, the other by chemists and druggists not belonging to that body. The Bill of the latter is confined to England and Wales, that of the former to Great Britain.

After carefully considering both Bills, the Committee are of opinion that the preferable mode of legislation is that which adopts the Pharmaceutical Society, with the Pharmacy Act of 1852, as a basis. They think the Bill promoted by the Society well fitted to attain various important objects, and reasonable in its demands for powers and privileges.

The main objects of the Bill are to form a register of legally qualified pharmaceutical chemists; to prohibit the use of certain pharmaceutical titles by persons not on the Register; to confine to those registered the privilege of executing the prescriptions of medical practitioners, subject to the provisions hereinafter named; but not to restrict the sale of medicines asked for in any other manner.

The Committee desire to bring before the Council certain defects which it appears to them necessary to correct before the Bill becomes law.

1. The Bill should be altered so as to apply to Ireland, as well as to England and Scotland. They are not aware that any state of things exists in Ireland to render the regulation of pharmacy by the State less necessary there than in Britain.

2. The Committee are of opinion that a clause should be inserted in any Pharmacy Bill, rendering it imperative on chemists and druggists to follow, in compounding prescriptions, the formularies of the *British Pharmacopœia*, unless otherwise directed by the prescriber.

3. The Committee consider that the promoters of the Bill, probably from a desire to disarm opposition, propose to admit, on too easy terms, into their Society practising chemists and druggists not now belonging to it. The proposal is to admit all who offer themselves for examination, or who produce a certificate from a qualified medical practitioner that they have been in the practice of dispensing medicines from the prescriptions of medical men before January 1, 1866. The latter alternative implies a facility of entrance which will be apt to lead to abuse. The Committee are of opinion that more satisfactory evidence of qualification should be required.

4. The last important defect in the Bill which the Committee have to notice is, that no adequate provision has been made towards preventing registered pharmaceutical chemists from converting themselves into unqualified medical practitioners.

Looking to the history of medical practice in this country, the Committee see great danger to the interests of the public and of the medical profession from the body which will be constituted by the Bill, should it become an Act in its present shape. The General Medical Council, in carrying out the objects of the Medical Act, have raised, and, it is hoped, may further raise, the qualifications of legally qualified medical practitioners. But their labours will be in vain, should the creation of a new race of unqualified practitioners be inadvertently encouraged by an Act of Parliament. It is well known that many existing chemists and druggists, both members of the Pharmaceutical Society and others, practise medicine, although unqualified by law and not competent by education. To a limited extent, this practice may be inevitable, and, at all events, cannot be prevented. But the existence of it gives peculiar facilities and temptations to the pharmaceutical chemist to embark largely in irregular medical practice as an unqualified practitioner.

The Committee have considered whether the danger here indicated might not be averted by extending the jurisdiction of the General Medical Council, so as to include control over pharmaceutical chemists as well as over practitioners in medicine. But they believe that such a plan is at present attended with difficulties.

By Clause 55 of the Medical Act, chemists and druggists are expressly exempted from the provisions of the Act, so far as the “selling, compounding, and dispensing medicines” is concerned. Nor is there any provision in the Act which gives the Medical Council any greater power to prevent chemists and druggists from practising medicine also, than the Act enables the Council to exercise over all other unqualified medical practitioners. It is plain, therefore, that the Act did not contemplate the exercise by the Medical Council of any control over chemists and druggists; and the Committee consider that it would be unwise to seek to alter the existing relations between the Medical Council and chemists and druggists.

The Committee have further considered whether the danger they have pointed out might be averted by some simple provision in the Pharmacy Bill. By Section xvii of the Bill of the Pharmaceutical Society, it is declared that—

“Nothing in this Act contained shall extend, or be construed to extend, to lessen or prejudice, or in any wise to interfere with, any of the rights, privileges, and immunities heretofore vested in, and exercised,

and enjoyed by any duly qualified medical practitioner."

This clause sufficiently protects medical practitioners in such right of practising pharmacy as they have hitherto enjoyed; but it does not attempt to prevent pharmaceutical chemists from practising medicine. Considering their peculiar temptations to practise it, however, some check seems desirable. The Committee suggest that this object may be attained, in some measure, were the following clause to be added to Section XVII; viz.—

"Or to entitle any person registered under this Act to practise medicine or surgery, or any branch of medicine or surgery."

The members of the pharmaceutic body would thus have constantly before them the sentiments of the legislature as to the principles on which the Pharmacy Act was founded.

The Committee have reason to believe that the Council of the present Pharmaceutical Society have every desire to discourage the practice of medicine by its members. They, therefore, apprehend that no opposition would be made to the addition of such a clause.

The Committee call attention to the fact that the Bill proposes to confer on the whole body of chemists and druggists the right of dispensing and selling medicines without any control on the part of the Government, except such as is exercised under the Pharmacy Act over registered pharmaceutical chemists. The medical profession has not been so dealt with in the Medical Act. The Medical Council is properly restricted in its action by the Medical Corporation and Universities, and is also controlled by the Privy Council. They submit that the whole profession of pharmacy ought to be subjected to some control.

The Committee recommend that the above observations should be laid by the President before the Secretary of State for the Home Department, and the Chairman of the Select Committee on the two Bills.

Signed on behalf of the Committee,
HENRY W. ACLAND, *Chairman*.

Returns from the Licensing Bodies. Dr. EMBLETON moved, Mr. HARGRAVE seconded, and it was resolved—

"That the Report of the Committee on Returns received from the Bodies in Schedule (A), and the Registers of Medical Students be adopted." (See p. 403-4.)

Finance. Dr. SHARPEY moved, Dr. STORRAR seconded, and it was resolved—

"That the Report of the Finance Committee be adopted." (See page 402.)

Dr. SHARPEY remarked that the balance due on account of the *Pharmacopœia* was now reduced to £674.

Dr. SHARPEY moved, Dr. STORRAR seconded, and it was resolved—

"That the Resolution adopted on the 7th of May, 1864, directing that two members of the Executive Committee be annually appointed to audit the accounts of the Council, be rescinded, and that the Standing Order, Sect. VI, No. 14, founded thereon, be repealed."

The Registrar. Dr. PAGET moved, Mr. ARNOTT seconded, and it was resolved—

"That it be delegated to the Executive Committee, in case of the death or incapacity from illness of the Registrar, when the General Council is not in Session, to appoint a person to perform temporarily the duties of Registrar."

The King and Queen's College of Physicians. Dr. CORRIGAN moved, Dr. APJOHN seconded, and it was agreed to—

"That the correspondence, as now submitted, between the Director-General of the Army Medical Department, the Secretary of State for War, the General Medical Council, and the King and Queen's College of Physicians in Ireland, be inserted in the minutes, and that the Registrar be requested to write to the Secretary of State for War, enclosing a printed copy of the above, and explaining to his Lordship that the General Medical Council are of opinion, for the reasons stated in the correspondence mentioned above, that initials, indicating the several medical qualifications which army surgeons possess, should be inserted after their names without distinction or preference to one degree or license over another, each surgeon, when he possesses more than one medical qualification, having, however, only one medical qualification appended to his name."

The standing orders were here suspended so as to enable the Committee to sit until seven o'clock.

The Army and Navy Returns. Dr. CORRIGAN moved, Dr. APJOHN seconded, and it was resolved—

"That a letter be addressed to the Director-General of the Army Medical Department, requesting that he would direct the future returns from the Army Service to have columns attached similar to those in the Navy return, specifying in similar detail the number of Candidates and the heads under which the Candidate failed to answer."

Business of the Council. It was moved by Dr. ACLAND, and seconded by Dr. STOKES—

"That a Committee of not more than five, and the President, be appointed to consider and report to the Council what are the means best calculated to expedite the business of the General Council; and, what are the several objects on which the funds of the Council may, consistently with the spirit of the Medical Act, be expended."

After some discussion, the motion was negatived; 4 voting for and 9 against it.

Recommendations on Medical Education, etc. Dr. EMBLETON moved, Dr. LEET seconded, and it was resolved—

"That the Report of the Committee appointed to arrange and digest the recommendations as to education and examination agreed to during the present session by the General Committee on Education to be considered, be adopted, and that the recommendations therein embodied be printed, under the direction of the Executive Committee, in a separate form, circulated among the members of the Council, and sent to each of the licensing bodies."

Visitation of Examinations. Dr. CORRIGAN moved, Dr. APJOHN seconded, and it was agreed by a majority of 7 to 4—

"That this Council, in recommending in their resolution of April 6th, 1865, the visitation of examinations by the Branch Councils, or members of such Councils deputed by them, did not contemplate payment for such duties."

The Executive Committee. It was moved by Dr. ANDREW WOOD, and seconded by Dr. EMBLETON—

"That the powers and duties delegated to the Executive Committee, in accordance with Section IX of the Medical Act (See Standing Orders, Section VI), shall be vested in the Committee until the next meeting of the General Medical Council; and that, in addition, it be delegated to them to communicate with the government in order to carry out the views of the Council in regard to the Bill for amending the Medical Acts."

Dr. APJOHN moved as an amendment, and Dr. CORRIGAN seconded—

"That the words 'in order to carry out the views of the Council,' be omitted, and the following sen-

tence added to the foregoing resolution: "it being understood, however, that no concession shall be made by the Committee inconsistent with the Amended Bill proposed by the amended Council."

The amendment was carried by a majority of 7 to 4, and, having been put as a substantive motion, was also carried.

Publication of Proceedings. It was moved by Dr. CORRIGAN, seconded by Dr. ARJOHN, and agreed to—

"That a third volume be published, without delay, of the proceedings of the past and present meetings of the General Medical Council, with full index attached."

Votes of Thanks, etc. The following resolutions, moved by Dr. ANDREW WOOD, and seconded by Dr. AQUILLA SMITH, were unanimously agreed to.

"That the thanks of the Council are due, and are hereby tendered, to the Treasurers, Dr. Sharpey and Dr. Quain, for their important services.

"That the thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council.

"That a gratuity of twenty guineas be given to the resident officials of the College of Physicians, for services rendered to the Council.

"That a gratuity of ten guineas be given to Mr. Bell, and the same to Mr. Roope, the clerks, in consideration of their extra services during the present lengthened session of the General Medical Council."

Dr. EMBLETON moved, Dr. STOKES seconded, and it was agreed to—

"That the cordial thanks of this Council are due, and are hereby tendered, to Dr. Andrew Wood, for his unwearied exertions and invaluable services as Chairman of the Business Committee during the past and present session of the Council."

It was finally moved by Dr. ANDREW WOOD, seconded by Dr. CORRIGAN, and unanimously agreed to—

"That the thanks of the Council are cordially tendered to the President for his kind, courteous, and efficient services during the present session of the General Medical Council."

The minutes of the day's meeting were then read and confirmed; and the eighth session of the Medical Council was brought to a close after a sitting of eleven days.

In concluding this report, we would express our thanks to the Council and the College of Physicians for the accommodation afforded us; and also to the clerks, Mr. Bell and Mr. Roope, for the obliging manner in which they placed copies of the minutes and other available documents in our hands at the earliest possible opportunity, and furnished us with all other necessary information.

THE NEW HOSPITAL AT CAMBRIDGE will probably be completed in the course of three or four months.

HEALTH OF SCOTLAND. The Scottish Registrar-General's monthly return for the eight principal towns—containing an aggregate population of probably above 922,000—shows a mortality of 2,593 for the month of March. This is 147 above the average mortality of the month, but it is 322 less than the month of March 1864. Epidemic diseases, however, still prevail; the zymotic class of diseases caused one in every four of the deaths of the month, one in every three in Paisley, and nearly half of all the deaths in Perth. Above 11 per cent. of the mortality of the month was from typhus, which in Greenock caused nearly 20 per cent. of the entire mortality.

WE beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, APRIL 22ND, 1865.

THE MEDICAL COUNCIL.

THE members of the General Council of Medical Education and Registration have again met, have deliberated during a session of eleven days, and have departed. The Council has had before it several important subjects, among which the most prominent were Medical Education, the Amendment of the Medical Act, and the Pharmacy Bills. What has been the result of its labours?

The first subject to which the Council directed its attention was the amendment of the Medical Act. Last year, it was determined that the consideration of the subject should be deferred for the time; that the Branch Councils should be requested to consider how Sections XX, XXXI, and XL of the Act could be best amended; and that the Council should appoint an early day at their meeting in the next session (that which has just been held) for the examination of the whole subject. Accordingly, on the first day of the session, the Council, after disposing of some formal business, proceeded to deliberate on the Act; and the several recommendations of the Branch Councils were read and placed on the minutes. The Council first debated on the sections above mentioned, and subsequently entrusted the Medical Act to a Committee, with the view of a more extended examination.

On Section XX, which gives the Medical Council the power of representing to the Privy Council the conduct of those licensing bodies whose requirements do not come up to a proper standard, various proposals were made by Dr. Andrew Wood, Mr. Syme, and Dr. Parkes. (See JOURNAL, April 8, p. 352.) Neither of these, however, met with sufficient favour to carry them; and it was ultimately decided to leave the section as it at present stands. The Council was, we believe, led to this decision by the very valid argument that it would be absurd to ask for an increase or modification of its powers under this section until it has ascertained by experiment—which it has not yet done—that these powers are not sufficient. The Council, in fact, adopted the resolution of the Branch Council for England:

"That, consistently with the existing provisions of the Medical Act, the Medical Council may make

known what they consider to be requisite as a sufficient course of education and examination, and may, if needful, represent cases of deficiency to the Privy Council, for correction; and that the Medical Council has, further, the power of supervising examinations, with a view to their efficiency;—that hitherto these provisions of the Act have not been proved by actual trial to have failed of their purpose, and that it would be impolitic to apply to the legislature for other powers until those already conferred shall have been practically shown to be insufficient.”

For Section XL—the penal clause of the Medical Act—the Council resolved to substitute a clause to which we have already directed attention as being objectionable. Notwithstanding the arguments adduced by several members in favour of compulsory registration, we still regret that the Council decided on omitting the words “nor being able to give evidence of being qualified to be registered under this Act”.

The Council having thus come to a decision with reference to Sections XX and XL, on a subsequent day referred the whole of the Act to a Committee, together with suggestions from certain members of the profession and an important memorial from the Dental Licentiates of the Royal College of Surgeons. The Report of this Committee, and the decision at which the Council arrived in regard to it, will be found at pages 398-402 of the present number.

The Committee laid before the Council the draft of an amended Bill, which, with some modifications, was adopted. By it, Sections XIV and XL of the present Act are proposed to be repealed, such repeal not having a retrospective effect. For Section XL, the clause to which we have already referred is substituted. Section XIV of the present Act defines the manner in which the *Register* is to be kept. Of this section the spirit has been preserved; but it is proposed to amend it by directing the Registrar, in cases of doubt, to apply twice, at intervals of three months, to practitioners before erasing their names from the *Register*; and also by enabling the Registrar to remove the name of any one who has ceased to practise and wishes his name to be erased. No name which has been once struck off is to be restored to the *Register* without the authority of the General Council or Branch Council.

In the seventh section of the Medical Act, the representatives of the corporate bodies in the Council are required to be “qualified to be registered”. This wording was obviously necessary when the Act first came into operation; but now the Council propose that the representatives of the corporations shall absolutely be registered.

The Committee further recommended that the privilege of granting licenses in Dental Surgery, already possessed by the Royal College of Surgeons of England, should be further conferred on Scotch and Irish surgical corporations. This proposal was, however, objected to on the ground that it would not be fair to

exclude the Universities and the Colleges of Physicians from a similar privilege; and the clause was accordingly withdrawn without much discussion.

Several other questions, arising out of suggestions made by various practitioners and by members of the Council, were also taken into consideration by the Committee; viz., the introduction of a clause to compel practitioners to obtain both a medical and surgical qualification before registration; the application to Parliament for a grant of money to defray the expenses of visitation of examinations; and an application for increased powers to be given to magistrates administering the Act, and for increased penalties. On these points, the Committee recommended that no action should be taken; and the Council endorsed their recommendation. The Council, however, considered it highly desirable that all registered practitioners should have a double qualification; and again expressed an opinion in favour of combined action on the part of the Colleges of Physicians and Surgeons in each division of the kingdom. In reply to the memorial of the dental surgeons, the Council resolved, on the recommendation of the Committee, that it is not expedient to open the *Register* to dental practitioners having no other qualification than their licence to practise dentistry; because such admission would further frustrate the desire of the Council to secure a full qualification for all registered practitioners.

The Council completed its proceedings in regard to the amendment of the Medical Act by authorising the President to address a memorial on the subject to Sir George Grey, and by sending a deputation to the Under Secretary for the Home Department. This deputation was received by Mr. Waddington on Saturday last, and met with what was considered to be an encouraging reception. Whether, however, it will be possible to obtain the passing of a Bill during the present session, is somewhat doubtful. Some members, Dr. Corrigan especially, regard the attempt as useless; and there is, we fear, much reason in their arguments. We shall, however, soon see how far they are right.

The two Pharmacy Bills, now before Parliament, also received the attention of the Council. A Committee appointed for the purpose brought up a report on them which, with some modifications, was adopted. The Council prefers the Bill of the Pharmaceutical Society—that introduced by Sir Fitzroy Kelly; but proposes that the Bill should be made applicable to Ireland as well as to England and Scotland; that a clause should be introduced rendering it compulsory on druggists to follow the *British Pharmacopæia* in compounding prescriptions, unless otherwise directed by the prescriber; that more satisfactory evidence of qualification than that mentioned in the Bill should be required from druggists seeking admission into the Pharmaceutical Society; and that some provi-

sions should be made to prevent chemists and druggists, registered under the proposed Act, from acting as medical practitioners. The Pharmacy Bill, it is observed, proposes to protect the rights, as to pharmacy, of duly qualified medical practitioners; and it is further proposed to add a clause to the effect that no registered pharmaceutical chemists shall be entitled to practise medicine or surgery. Illegal practice by druggists to some extent, the Council acknowledged, cannot be prevented; but it desires that the Bill should contain an expression of discouragement of such practice. The Council further urges that the profession of pharmacy should be placed under some control analogous to that which is exercised over the Medical Council by the Universities and corporations, and by the Privy Council.

Medical Education occupied a considerable share of the time of the recent session. The proceedings were at first carried on in a rather desultory manner; various members bringing forward resolutions without any definite order, until Dr. Quain very opportunely recalled to the memory of the Council a fact which seemed to have been overlooked; viz., that the report of a Committee on Education, which had been partly discussed and decided on last year, still remained for the consideration of the Council. Accordingly, discussion on this report was resumed and completed; the decisions arrived at in 1864 being also reconsidered and in several instances modified. We shall give in an early number the complete code of recommendations agreed on by the Council; and will here only point out the leading features.

All medical students are to be registered by the Branch Registrars at the commencement of their professional study; a preliminary examination in general education having been first passed. The licensing bodies are to be requested not to examine after October 1869 any candidates whose names are not on the Students' Register or on the general *Medical Register*. Special exceptions, however, may be admitted by the Branch Councils, if sufficient reason be given. No license is to be obtainable until after the expiration of forty-eight months from the time of the student's registration; and within this period he must have attended a medical school recognised by any of the bodies in Schedule A, during not less than four winter sessions, or three winter and two summer sessions. The Council still declines to lay down any special course of study to be followed; but advises that lectures should be so arranged as not to interfere with hospital and clinical study. As to examination, the Council have resolved to ask the licensing bodies for particulars regarding the manner in which their examinations are carried on. This information, although only suggested by a recommendation of last year's Committee not then formally adopted, has already been

furnished by some of the licensing bodies. The examination is to consist of two parts: the first not to be undergone until the close of the winter session of the second year of study; and the second part not before the close of forty-eight months after the registration of the student. Candidates may, however, be examined in physics, botany, and natural history, at an earlier period than the first professional examination. The examinations are to be held, except in special cases, at stated periods; and the professional examinations are to be practical in all branches in which they admit of being so. No candidate is to be admitted to his final examination until he is 21 years of age; but special exceptions may be made, and the reasons for the same must be transmitted to the Branch Council.

One very important decision at which the Council arrived was, to organise the visitations of examinations.

"Each of the Branch Councils, or such of their members as may be deputed by such Councils, shall from time to time visit the examinations, preliminary as well as professional, conducted by the qualifying bodies in their respective divisions of the United Kingdom, and report the results of their observations to the General Council."

We are glad to see that the Council have at last recognised the necessity of exercising some supervision over the examining bodies. Whether they have adopted the most efficient scheme, remains yet to be proved; but we cannot but think that the expression of their determination at least will have a beneficial effect. A proposal of Dr. Corrigan, who disapproves of visitation, that the examinations of each licensing body should be public to the graduates, members, and licentiates of that body, was rejected.

In the course of the proceedings, two very important documents, having a bearing on medical education, were laid before the Council; viz., the Returns from the Directors-General of the Army and Navy Medical Departments of the number of candidates admitted to examination during 1864. These returns, which are given at p. 372 of last week's JOURNAL, apparently had an influence on the deliberations of the Council, especially in demonstrating the necessity of supervising examinations. They showed that, in the Army Medical Department, out of 151 candidates who presented themselves, each of whom had been already declared by two licensing bodies fit to practise medicine, 30 were rejected; while, in the Navy, no fewer than 21 out of 49 were rejected. The Naval Board of Examiners appended to their return a letter, in which they observed that "in a very large number of cases, the candidates displayed a lamentable ignorance of Latin"; and that they regretted the general want of instruction in operative surgery in the dead body.

The Returns received from the Licensing Bodies shewed a considerable decrease in the number of stu-

dents who passed the first examination, as compared with last year's return; while there was an increase of those who presented themselves at the second examination.

Year of Return.	Passed.		Rejected.	
	1st Exam.	2nd Exam.	1st Exam.	2nd Ex.
1864	1708	1687	375	224
1865	1493	1738	309	227

The percentages of rejections at the two examinations respectively have been nearly the same in the two returns; viz., for the first examination, 17 last year and 18 this year; and for the second, 11.5 in each of the two years.

This year, a Register of Students has been laid before the Council. This return gives the total number as 1315, of whom 1210 had passed a preliminary examination before commencing professional study, and 105 were exempted for various reasons. It is observed, that the number of exemptions is considerably less than in previous years.

On the subject of General Education, Dr. Stokes, as Chairman of a Committee, brought up a report in which it was recommended that the preliminary general examination should, after 1867, be left to the national educational bodies recognised by the Medical Council; and that no certificate should be accepted which did not show the candidate to have a knowledge of Latin, and of the elements of geometry, mechanics, and hydrostatics. The consideration of this report was, however, deferred, for want of time, until next session.

From the *Pharmacopæia* Committee, we learn that a new edition of the *British Pharmacopæia* is in course of preparation, and that certain improvements are to be made in it. It is not, however, to appear before the next session of Council. From the financial statement, it appears that 722 copies of the large and 1300 of the small edition were sold between May 1864 and January 5, 1865; and that the stock on hand of the large edition is 103 out of 13000 copies, and of the small 10,917 out of 15,000. The balance due on account of publishing has been reduced from £1206 to £723.

The Balance-sheet of the Council for 1864 shews a deficit of £59:11:6½, although the receipts were greater than in 1863 by above £130, and there was in 1863 a balance in favour of the Council amounting to £917. The contrary balance is chiefly due to the increased expenditure on behalf of the General Council, which in 1863 amounted to £3338, and in 1864 to £4317. The expenses of the Branch Councils have also, but in a less degree, been increased, having been £1210 in 1863, and £1339 in 1864.

We have thus given the principal points brought forward in the recent session. Other matters there were, for an account of which we must refer to the reports of each day's proceedings. On reviewing the proceedings, we are disposed, without pledging ourselves to an approval of all that the Council has

done, to give it credit for less of eloquence and more of work than on previous occasions. At all events, the members seem to have endeavoured to act under the conviction that the profession expects something from them more than they have already done. One day, indeed, may be regarded as having been spent altogether unprofitably. On Saturday, April 8th, the Council were occupied for an hour in discussing an opinion of counsel on their duties as to voting, which, however, was so obscure, that the President declared himself unable to learn from it what he ought to do, and Dr. Andrew Wood compared it to the celebrated oracular answer, "Aio te, Æacida", etc.; and after this, nearly three hours of precious time were taken up with that apparently interminable question, the privileges of the Irish Apothecaries—the result being, to leave matters precisely as they were. But, with this exception, something was done, or some important matter discussed, at each day's sitting.

The Council has this year, we repeat, improved in its shew of work. And this must be admitted: that, whatever may be their shortcomings, credit is due to the members of the Council for their assiduity in attending to their duties. During the recent session, one member only, Dr. Alexander Wood, has been absent—we regret to learn, from illness. It seems, in fact, a point of honour with them, at least by their attendance to fulfil the trust placed in their hands by the licensing bodies which they represent. And this many of them must do at a pecuniary loss to themselves; for it cannot be supposed that the five guineas *per diem* with the allowances for hotel and travelling expenses which each member receives constitute an adequate return for his absence from practice. It would be an improvement, however, if some means of remunerating the members could be devised which should press less heavily on the funds of the Council. Dr. Acland, indeed, made an unsuccessful attempt to obtain a Committee to consider how the business might be abridged; but the Council thought that in time the business will, without any aid from Committees, naturally and necessarily contract itself within more reasonable limits than those to which, in the last two sessions, it has extended.

THE opinion which this JOURNAL was the first of the medical journals to give—viz., that the so-called new disease said to have been raging in St. Petersburg was "evidently neither plague nor any new disease, but the plain old-fashioned famine-fever, typhus, with its companion, relapsing fever"—has turned out to be strictly accurate. There have evidently been gross exaggerations made by the papers and telegrams in reference to the destructive character of the disease. It seems to us that the duty of medical journals in cases of this kind is not

to feed and foster the popular craving after excitement, by giving heed to the popular, though ignorant, and the marvellous side of such reports; but to calmly survey, and philosophically estimate, their real meaning. It surely is not the business of medical journals to square their medical knowledge according to the capacity of the ignorant multitude. Our duty should be to try and elevate ignorance up to a level with scientific teachings. An official document issued by the Russian Minister of the Interior gives us, no doubt, something like an accurate statement of facts. From this we learn that the epidemic in the Russian capital is neither Black Death nor Oriental Plague. "The epidemic," says the Minister, "does not offer any new features of note, nothing unknown to science, no special form but the typhoid class, with various known modifications," among which "buboes" are not mentioned. Typhus and typhoid fever visit St. Petersburg in the autumn of almost every year, diminishing about November, when a great number of workmen quit the city for the provinces, and increasing again in the spring, when these workmen return and the ice breaks up. This year, the customary spring outbreak has been more severe than usual, and attended with "bilious typhoid fever" and "relapsing fever". The last appears to be new in St. Petersburg. The relapsing fever is contagious. Only two deaths had been reported among the doctors, and a few more among the nurses. Infection has been most virulent in the poorest dwelling-houses, where the ventilation is bad, and infected clothing rarely destroyed. The Russian physicians express no doubt as to the origin of the malady. "It may be attributed to bad hygienic arrangements; to the consumption of bad food; to an unusual agglomeration of workmen in the capital." Nothing is said about the "horned rye", on which so much stress had been laid. Of the pathology of the disease, no doubt the medical men who have been sent by the English Government to the seat of the fever will give us a more accurate and satisfactory account than that contained in the report of the Russian Minister. Information, moreover, has been received from Dr. Whitley.

"He arrived," says Mr. Simon, "at St. Petersburg on Saturday night last, and his telegram informs me in positive terms that 'nothing resembling plague has been observed'. As regards the disease which is prevailing in parts of North Germany, the case is very widely different. That disease is one of which hitherto England has had no general experience. Even in foreign medical literature, mention of it is but comparatively recent, and the knowledge which relates to it is incomplete. It is a febrile nervous affection of a very painful and very dangerous kind. By us, for practical purposes, it may be regarded as a new disease; but, in truth, it has for the last twenty-eight years been prevailing very extensively in successive small epidemics, both in Europe and in America, throughout the entire breadth of the north temperate zone. Both on account of the alarming rumours which are connected with the present epi-

emics in North Germany, and also with a view to collect the latest and fullest information concerning the habits of so important a disease, your lordship (as in the case of the St. Petersburg fevers) deemed it right that an English physician should be sent to observe and report; and, under your lordship's orders, I instructed Dr. Sanderson to proceed for this purpose to those places about the Lower Vistula where the disease was chiefly prevailing. From him during the last few days I have received telegrams and letters which leave no doubt as to the identity of the prevailing disease, and establish, as I have already stated, that it has no dependence on the fevers of St. Petersburg."

THE profession, who approve of fair play, will be glad to learn that the treasurer of St. Thomas's Hospital has not succeeded in his attempt to deprive Mr. Solly of the privileges of his hospital appointment. So far from this, the treasurer, on the 18th inst., received a very considerable defeat; for it was decided, by a majority of forty-five against eighteen governors, that Mr. Solly should be allowed to hold his appointment of surgeon to the hospital for the full term of twenty years. We believe that Mr. Solly has still eight of the twenty years of office to run.

THE Vaccination Committee of Lyons have just published their Annual Report. Every year, they tell us, adds something new to a subject which has been long ago thought exhausted. M. Palasciano of Naples had supplied matter from the cow, and with this some children and animals at Lyons had been vaccinated. In its use, it appears that certain precautions are requisite. Professor Chauveau states that the matter from the cow never fails when the rules laid down by M. Palasciano are duly attended to; and that it produces finer pustules than the ordinary ones, and is absolutely harmless. One of the most essential rules is, that the matter must be taken from a pustule which is not more than seven days old; and that it must be taken from the very bottom of the pustule. The liquid matter, which may be obtained in abundance from the surface of the pustule at the eighth or ninth day, appears to have only very feeble inoculating powers. Thus eleven inoculations, made with matter taken from the bottom of young pustules, all succeeded perfectly; whilst five inoculations, made with matter taken from the surface of the pustule on the eighth day, all gave negative results. M. Chauveau thinks that we should employ animal vaccination as a means of avoiding syphilitic contagion. But the head surgeon of l'Antiquaille—M. Gailleton—gives a much more moderate view of the question. In his opinion, vaccination from the cow is a method which can only be very rarely employed, and is not required as a preventive against syphilis, if only due precaution be taken by the vaccinator. M. Berne, also head surgeon of

the Lyons La Charité, affirms that vaccine matter has in no way degenerated, and is still as effective a preventive against small-pox as ever it was. Altogether, it would appear that the experiments made at Lyons with vaccine matter taken from the cow do not correspond precisely with the account given by M. Palasciano at the Lyons Congress. The Lyons Hôtel-Dieu is, we are told, a permanent focus of variolous infection, both of patients and of visitors; so that the vaccination of every patient on admission has been recommended.

THE bromide of potassium, as a remedy for epilepsy, has been tried by M. Moreau, in the Salpêtrière. Of the 300 or 400 epileptics in that hospital, the youngest patients, and those most recently affected, were chosen for the trial. The treatment was continued for three months, and the dose gradually increased from the first to the sixth week, from half a *centigramme* to three *grammes* in the twenty-four hours. After the sixth week, the three *grammes* were continued up to the end of the treatment. The result of the treatment in fifteen patients was, that in the first category of patients the bromide-salt produced neither good nor harm, the epileptic fits continuing as before. In the second category, the fits were more numerous after than they were before the treatment. The conclusion, therefore, is that the bromide is completely inefficacious in confirmed epilepsy.

HOMŒOPATHY appears to be in the ascendant in Spain. Recently, there has been established a Chair and *Clinique* of Homœopathy at Madrid. There is also a Homœopathic Academy, whose President, José Nanez, is a Marquis and Grand Cross. The Minister of State has determined that a fair trial should be given to homœopathy, in order to ascertain whether it will or not be right to alter, for the future, the course of medical instruction. All medical Spain is in commotion at the proposal. The Academy of Medicine has sent a protest to the Senate. "When Spain moves, instead of advancing, it progresses backwards," says the critic.

The Medical Congress at Madrid begins on next September 24th; it lasts six days. Any one, on showing his medical diploma, can gain admittance. The chief subjects proposed for discussion are: Hospital Reforms; Histological, Chemical, and Clinical Analysis of Purulent Infection; Nature and Treatment of Typhoid Fever; etc. The papers and discussions may be carried on in the French language.

The administration of nitrate of silver in ataxia of locomotion, and other paralytic disorders, is highly spoken of by certain French practitioners. The nitrate of silver should be made into a pill with nitrate of potash or silica, and not with bread, which decomposes it.

"No one can give an opinion concerning the acts of lunatics brought before the courts of justice," says M. Legrand du Saulle, "who has not had large experience of patients in lunatic asylums. He who does so speaks of that of which he has no knowledge—of what he has not seen; and the consequence is, that his incompetent evidence may lead the judge or the jury to the most unfortunate conclusions."

M. Guibout, of St. Louis, in lead-poisoning, speaks highly of flour of sulphur given in honey. Half an ounce of the sulphur is given during the day. It purges gently, and also directly neutralises the lead, says M. Guibout.

Dr. Chabraud states that cretinism has been for the last twenty years on the decrease in the Briançon district, and attributes the fact, in great part, to the use of coffee, which has there become very general.

M. Musse recommends a creasote lotion as a specific for mentagra.

M. Chenu, army physician, has just published a full exposition of questions, hygienic, medical, and surgical, relating to the Crimean war, founded on official documents. His work contains eight hundred pages in quarto, and is illustrated with one hundred engravings. He gives therein an account of the "courageous victims which were gathered by death from amongst the ranks of medical military service during the Crimean campaign." The number of officers of all ranks who died from wounds was 779, or 17 per cent.; of medical officers who died of different diseases, was 82, or 18.22 per cent.; of officers of all ranks who died of typhus, was 26, or 0.17 per cent.; of medical officers who died of typhus, the number was 58, or 12.88 per cent. Speaking of the position of the military medical officer, M. Chenu says:

"What is the position of the military surgeon? In the eyes of the soldier, he has the reproach of being a non-combatant. His real value, however, is only felt on the field of battle, in the ambulance, in the hospital, and in the midst of contagious diseases. In the hour of danger, every one praises him. The medical man who dies in the fulfilment of his sacred duty, says *Moniteur de l'Armée*, deserves as well of the army, of his country, and of his sovereign, as the soldier who dies on the field of battle. But when the danger is passed, then kindly thoughts vanish. But, in truth, in what particular does he differ from the combatant? He marches with the ambulance on to the field of battle. He is neither protected from death nor from wounds. The only difference which there is between him and the combatant is, that he does not return the wounds which he receives. In the hospital, his position is still more dangerous; there he strives with invisible enemies, against whom he has no defence, unsustained by the ardour of battle, the excitement, and the sound of the trumpet."

ODONTOGRAPHIC SOCIETY OF PENNSYLVANIA. On February 7th, Professor Thomas H. Huxley, F.R.S., F.L.S., was elected an honorary member, and Charles James Fox, M.R.C.S., L.D.S., a corresponding member of this Society.

Association Intelligence.

CHEMISTS AND DRUGGISTS BILL.

THE following amendments have been proposed to be inserted in the No. 1 Bill (Sir F. Kelly's) by the Parliamentary Bills Committee of the Metropolitan Counties Branch of the British Medical Association. To Clause 17, which saves the rights of medical practitioners, it is proposed to add: "And it shall not be lawful for any person registered under this Act, to prescribe for any patient, or undertake the treatment of disease, or in any way assume to act as a medical practitioner, and every chemist and druggist so offending, shall, upon a summary conviction, forfeit or pay a sum not exceeding £10." As Clause 19, it is proposed to insert the following: "No patent, quack, or other medicine shall be sold, unless a sworn certificate of its composition be lodged with the Registrar appointed under this Act, and a copy thereof be open for inspection in the shop or place in which such medicine is sold; and any person or proprietor of a shop, selling any secret remedy, shall, on summary conviction for each such offence, be liable to a penalty not exceeding £20."

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE next meeting will be held at the Committee Room of the Dartford Union House, on Friday, April 28th, at 4 P.M.

Dinner will be ordered at the Bull Hotel, at 5.15.

Tickets 5s. each, exclusive of wine.

Flaxman Spurrell, Esq., F.R.C.S., will preside; and a paper is promised by John Grantham, Esq., on Fibrous Disorganisation of the Stomach and Pylorus.

FREDERICK J. BROWN, M.D., *Hon. Sec.*

Rochester, April 19th, 1865.

WEST SOMERSET BRANCH: QUARTERLY MEETING.

A QUARTERLY meeting was held at Clarke's Castle Hotel, Taunton, on Wednesday, April 12th, at 7 P.M. HAMILTON KINGLAKE, M.D., President, in the Chair. Eight members were present.

Annual Meeting. It was resolved that the annual meeting be held at Taunton, on Tuesday, July 4th.

Communications. The following communications were read:—

1. On the Value of Perchloride of Iron in Obstetrics: with Cases. By Hugh Norris, Esq. After a full discussion, and thanks to Mr. Norris for his useful hints, he was requested to send the paper to the JOURNAL for publication, as it was calculated to make better known so valuable a remedy.

2. A Case of Phlegmasia Dolens in a Boy aged 11. By H. J. Alford, Esq. Copious notes of this unusual disease occurring in so young a subject were read by Mr. Alford, and commented upon.

The meeting separated at ten o'clock.

UNIVERSITY OF LONDON. The Senate of the University of London have determined to establish a degree of Bachelor of Surgery, which may be granted at the same time as the degree of Bachelor of Medicine.

Reports of Societies.

LIVERPOOL MEDICAL INSTITUTION.

MARCH 9TH, 1865.

HENRY LOWNDES, Esq., Vice-President, in the Chair.

Acupressure. Mr. HIGGINSON gave an explanation of an instrument he had invented for the application of acupressure in external wounds.

Abnormal Arrangement of the Peritoneum. Mr. RAWSON showed a specimen of abnormal distribution of the peritoneum, the whole of the small intestines with the exception of the duodenum being contained in a sac formed by reflection of the peritoneum.

Ovariectomy. Dr. GRIMSDALE read four cases of ovariectomy. His previous successful cases had all continued to enjoy good health. One (Mary A. Smith) who was operated on in September 1863, was safely delivered of a child by Mr. Cavanagh, and has since with the child continued to do well.

CASE I. Margaret Robinson, aged 28, unmarried, a sempstress, was a thin delicate woman. Menstruation had continued regular, lasting usually four days. On examination a tumour was found, as large as the uterus at the eighth month, occupying the abdominal cavity; it was globular, uniformly fluctuating, and moveable most freely from the left side. The diagnosis at this time was unilocular tumour of the right ovary. On examining the chest, the percussion-sounds under the clavicle were not very clear; in the right subclavian region the respiratory murmur was harsh; on the left side it was weaker and interrupted. As there was no idea of performing ovariectomy at this time, no vaginal examination was made. She increased in size; and on January 8th, 1864, twenty-seven pints of ovarian fluid were withdrawn, followed by a total disappearance of the tumour. She rallied quickly and soon refilled. On May 14th she was again tapped, and thirty-two pints were withdrawn. On the 21st, a vaginal examination was made. The uterus was small and situated in front of the tumour. The tumour was somewhat fixed towards the left, and some pelvic adhesions were diagnosed. Ovariectomy was performed on June 14th. Several adhesions were met with. The peduncle was hard and fleshy, of good length, and a medium-sized clamp embraced it. The wound was closed by five deep and two superficial sutures. There was very little shock from the operation, and a remarkable freedom from pain; but one opiate was given, and that three hours after her return to bed. Sixty-eight hours after the operation all the sutures were removed, the wound having appeared to heal by first intention. She progressed satisfactorily, and left the hospital on July 9th. After leaving the hospital she suffered from abscess in the iliac region of the abdominal parietes, and though for some time in great danger, she made a good recovery.

CASE II. Annie Dowdale, single, aged 18; first commenced to enlarge in the abdomen during February 1862. She was a small delicate-looking woman, with enlarged submaxillary glands. She had slight cough. There was a loud rasping bellows-murmur with the second sound of the heart, heard at the base. In the early part of the year 1862, she was in the Royal Infirmary for acute rheumatism with heart-complications. The respiratory murmurs beneath the clavicle were clear, but rather harsh. Her abdomen, which contained a globular uniformly fluctuating tumour, measured at the umbilicus thirty-four inches, and from the scrobiculus cordis to the pubes sixteen

inches. The tumour was moveable chiefly from the left side, and was diagnosed as a tumour probably of the right ovary. There was no solid matter to be felt, and no evidence of any adhesions. On January 27th, she was tapped to sixteen pints of pale clear fluid. On October 7th, she was tapped to twenty-two pints. On November 21st, she was tapped to twenty-three pints. On June 9th, 1864, she was tapped to twenty pints. The condition of the girl for undergoing so formidable an operation was such as to make it a most difficult question whether it would be justifiable to perform ovariectomy. At her urgent desire, however, her request was complied with. The operation was performed on July 5th, 1864. The peritoneum was found very closely adherent to the tumour, causing delay in the early stage of the operation. There were no pelvic or any adhesions posteriorly. A large apron of omentum was found closely adherent to the upper and anterior surface of the tumour; this when carefully stripped off bled pretty freely, and from so many oozing points that it was considered advisable to tie it in one mass, and to bring the ligatured part into the wound at its upper edge. The peduncle was long and very thin. There had been no escape of ovarian fluid into the peritoneal cavity; but from the torn adhesions and the omentum so much blood had been poured out, that it was necessary to sponge out the pelvic cavity freely. The wound was brought together by five deep and three superficial silk sutures. For some time after the operation she remained in a very weak condition. Dyspnoea came on apparently from a collection of mucus in the bronchial tubes, which considerably increased the danger of her condition. To remedy this, after other measures had failed, the whole of the front of the chest was painted with blistering fluid, followed by the application of a hot poultice. This had the desired effect, and she now gradually commenced to recover from her most dangerous condition. One deep suture was removed in forty-eight hours, and the remaining four in sixty-eight. She was discharged from the hospital on August 2nd perfectly well, and returned to service. One curious fact remains to be recorded, viz.: that the enlarged submaxillary glands of four years duration, disappeared within three weeks of the operation.

CASE III. Ellen Seddon, unmarried, aged 25, came to the Lying-in Hospital on May 13th, 1864, suffering from an abdominal enlargement. She first noticed the swelling in the summer of 1862. On examination, the tumour was as large as the uterus at the eighth month of pregnancy. The tumour fluctuated, and there were no indications of any solid mass; no adhesions could be detected. On examination *per vaginam*, the uterus was found lying centrally behind the tumour. There was a harsh respiratory murmur beneath both clavicles. She was ordered a tonic, and to remain under observation. She improved in general health, the tumour in the meantime increasing in size. A note was made that the tumour was probably of the right side. The operation was performed on September 24th, 1864. There were no adhesions except a small omental one. The tumour was chiefly bilocular. Twelve pints of thick portery fluid were drawn off; the pedicle was of fair length. Five deep sutures served to close the wound; these were removed, and nine hours after the operation the incision healing by first intention. She made an excellent recovery, and left the hospital quite well on October 29th, 1864. This patient called to see Dr. Grimsdale last week, and was in robust health.

CASE IV. Martha Budds, aged 32, married, was admitted into the Lying-in Hospital on September 12th, 1864. She had been suffering for three years from an abdominal tumour. She was tapped in May

1863, and three quarts of thick fluid withdrawn. There had been a watery discharge from the umbilicus which was very prominent. The abdomen presented a remarkably prominent appearance, caused by an egg-shaped tumour of large size. There was little if any fluctuation to be detected anywhere, and no evidence of ascitic fluid. The uterine cavity was found of normal length, directed towards the left side. The diagnosis being: "Large semi-solid and multilocular tumour of left ovary, generally adherent in front, and passing with some pelvic adhesions posteriorly." Her condition was fully explained; but after due consideration she determined to undergo any risk for the hope of getting rid of the disease.

Operation, Oct. 8th, 1 P.M. In consequence of the semi-solid nature of the tumour, an incision was made two inches above the umbilicus to the pubes. The tumour was very adherent in front; but down within the pelvis most formidable adhesions presented themselves, and when these were overcome, the tumour had a peduncle so broad and so thick, that it was hopeless to think of embracing it in the largest size clamp; it was therefore transfixed and tied in four separate portions, and the ligature cut short. For some two or three hours there was great tendency to collapse; but by 5 P.M. she was sick and complaining of pain. An opiate enema was given at 7.20, and at 7.45 she was asleep. She soon, however, commenced to sink, and in spite of all remedies, died twenty hours after the operation.

Dr. Grimsdale has now performed the operation ten times, seven cases having been quite successful.

The President, Mr. Higginson, and Mr. Steele took part in the discussion.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 28TH, 1865.

JAMES ALDERSON, M.D., F.R.S., President, in the Chair.

ON THE SOLVENT TREATMENT OF URINARY CALCULI: AN EXPERIMENTAL AND CLINICAL INQUIRY.

BY W. ROBERTS, M.D. (MANCHESTER).

[Communicated by Dr. BENGE JONES.]

THIS paper was divided into two parts. The first part was devoted to experiments and observations relating to the solvent treatment of uric-acid calculi by alkalis the urine by internal medicines. The inquiry started from two known data—namely: first, that uric acid is dissolved by solutions of the alkaline carbonates of a certain strength; and secondly, that alkaline carbonates can be introduced into the urine, so as to render it alkaline, by the administration of certain salts by the mouth. The practicability of dissolving renal and vesical calculi, composed of uric acid, by alkalis the urine, was inquired into under ten headings or sections.

1. Comparison of solutions of carbonate of potash and carbonate of soda shewed that solutions of carbonate of potash are better solvents for uric acid than solutions of carbonate of soda.

2. Comparison of solutions of different strength shewed that the greatest solvent power (for uric acid) lies in solutions containing from forty to sixty grains of carbonate to the imperial pint. Above this strength dissolution is soon prevented by the formation of a crust of biurate which invests the stone. Below this strength the solvent power gradually declines.

3. Comparison of the effects of varying volumes of solutions of constant strength shewed that the quantity of the solution permitted to pass over the stone,

between the limits necessarily imposed by the capacity of the kidneys to separate aqueous fluids, is of slight importance. A flow of three or six pints during twenty-four hours was found nearly as effective as a flow of eight or fifteen pints.

4. As to the absolute rate of dissolution of uric-acid calculi in solutions of the alkaline carbonates, it was shown that solutions of carbonate of potash, of the maximum solvent power, when passed at the rate of from three to eight pints in the twenty-four hours over uric calculi, at the temperature of the body, dissolve from ten to twenty per cent. of the weight of the stone each day.

5. The bicarbonate, acetate, and citrate of potash were found the most effective substances to alkalis the urine. Of the three the citrate was preferred. Forty grains of citrate of potash dissolved in five ounces of water, taken every two hours, alkalis the urine to a mean degree corresponding with the maximum solvent power of solutions of carbonate of potash.

6. The urine of a person taking full doses of citrate of potash, as recommended in Section 5, was passed over an uric-acid calculus at blood heat. The stone (weighing 180 grains) lost weight at the rate of twelve grains and a half in the twenty-four hours. In the performance of experiments on this point it came out that if the urine became ammoniacal (from decomposition of urea), it ceased to dissolve the uric acid, and the stone became invested with a crust of precipitated phosphates. Hence the deduction was drawn, that ammoniacal decomposition of the urine in cases of vesical calculi puts an absolute bar to the effectiveness of the solvent treatment by alkaline carbonates.

7. Two cases of complete dissolution of uric-acid calculi in the bladder were quoted from other authors. The author related three cases which occurred in his own practice. In none of the latter did complete dissolution occur. One of the cases proved to be an example of mulberry calculus; another, an alternating calculus of uric acid and oxalate of lime. This second specimen offered peculiarities of surface which indicated with certainty that dissolution of the uric acid had taken place; these peculiarities were explained by the aid of drawings of the stone after extraction. The third case proved abortive, apparently because the treatment was not carried on sufficiently long. In neither of the cases was the treatment carried out as effectively (as the later experience of the author showed) as it might have been. The principal instruction from the cases was the proof they offered that alkalis the urine does *not* cause the stone to be encrusted with a phosphatic deposit, so long as ammoniacal decomposition of the urine does not take place.

8. As to the cases in which the solvent treatment is and is not applicable, the conclusions were the following. The solvent treatment is inapplicable in all cases where the urine is ammoniacal. When the urine is acid (before treatment) the case is *primò facie* suitable for the alkaline solvent treatment; but exceptions must be made of cases where it is known or strongly suspected that the stone is composed of oxalate of lime, also where the stone is large. In cases where the urine is acid, and there is no indication of the nature of the stone, it may be either uric acid or oxalate of lime, or an alternating calculus composed of these two substances. Such cases deserve a trial of the solvent treatment for a limited period of a month or six weeks. The cases which are especially suitable for the solvent treatment are those in which (the urine being preliminarily acid) it is known or strongly suspected that the stone is com-

posed of uric acid, and has not yet reached any large size.

9. For carrying out the solvent treatment effectually, the urine must be kept *continuously* alkaline, and alkaline to a mean degree corresponding with the maximum solvent powers of solutions of carbonate of potash. The treatment must be given up immediately if the urine become ammoniacal.

10. The author examined some of the objections which have been urged against the principles of the solvent treatment.

The appendix to the first part contained some experiments showing that cystine is even more amenable to the alkaline solvent treatment than uric acid. The second part of the paper contains three sections. Section 1 contained experiments on the solvent treatment of uric-acid calculi by injections into the bladder. Solutions of the following substances were tried in a manner to imitate injections into the living bladder: bicarbonate and carbonate of potash, common phosphate of soda, basic phosphate of soda, borax, borax with liquor sodæ, potash soap, carbonate of lithia, liquor potassæ, and liquor sodæ. The results obtained demonstrated conclusively that their operation was so slow, that no practical advantage could be obtained from their use. Section 2 recorded some experiments on the effects of a solution of carbonate of potash and dilute nitric acid on oxalate of lime calculi: neither solvent promised any useful result. Section 3 showed the unsusceptibility of phosphatic calculi to solutions of the alkaline carbonates. Brodie's method of injecting dilute nitric acid into the bladder was imitated in one experiment, with results confirmatory of his statement respecting the use of this treatment in phosphatic concretions.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, MARCH 3RD, 1865.

G. POLLOCK, Esq., President, in the Chair.

On Melancholia. By G. F. BLANDFORD, M.B. The author first adverted to the theory of the pathology of insanity. No theory had yet been propounded fully accounting for the phenomena of diseased mind. Insanity had been thought due at times to inflammation, to irritation, and again to congestion. Some attributed it to altered nerve-force; others to a change in molecular substance. It was probable that each manifestation of nerve-force corresponded to a molecular change in the nerve-substance, and these changes bore a certain relation to the rhythmic nutrition of the nerve-substance, disease being a result of the loss or want of rhythm. No cases showed so plainly as these of melancholia, the important part which nutrition performs in the restoration of disordered mind.

The author chiefly brought forward the less severe and non-acute form of the disease, which recovered more than any other form of insanity when not complicated with serious bodily evil. The young are sometimes affected, but most frequently the patients are beyond middle age; it often happens at the change of life. Such cases illustrate well the emotional origin of insanity. Frequently simple depression is all that characterises them; beyond this the intellectual part of the brain may become involved, and delusions arise. At the commencement this disease is very insidious. The patient is out of spirits; he thinks everything is going wrong, or that he will be blamed for things altogether beyond his control. Every little matter worries him; the friends probably do not notice the complaint until these feelings be-

come ideas, and delusions take the place of emotional phenomena. The delusions usually assume one of two forms; a constant fear of some impending catastrophe, or a constant remorse for some fancied sin. These often run one into the other, and each may lead to suicide. The patient's health suffers; his nights are bad; he loses flesh. In nine cases out of ten there is disinclination to take a sufficient quantity of food. This refusal of food has been often attributed to dyspepsia; but in the author's opinion, dyspepsia did not occur here as a primary symptom. The state of the tongue and mucous membrane was due to the depressed nerve-force, and often to sheer starvation. Frequently the symptoms of dyspepsia vanish when food is given in large quantities. Sleep is generally deficient, and the patient wakes in a panic. The period of waking is generally that at which the greatest depression is felt; probably of the longest absence from food. Opium and its preparations agree with almost all these cases of depression. The opiate treatment of melancholia is now generally received as an established fact in therapeutics. Opium does not agree so well with women as with men. The bimeconate of morphia is the most useful preparation, and does not, like the acetate or hydrochlorate, produce nausea, loss of appetite, and constipation. Both food and stimulants must be given more freely than in health. Constipation must be met by gentle laxatives. The prognosis is generally favourable when no very acute symptoms are present.

These patients require change of air and removal from home. They must be stimulated by well chosen companions, and made to forget themselves by taking interest in the affairs of others. The medical, with the moral treatment, will usually produce a marked effect, and in a month or two the patient will often be well. When there is entire refusal to take food, and a determination to commit suicide, it will not be possible to treat the case safely except in an asylum.

Correspondence.

SYPHILISATION.

LETTER FROM HENRY LEE, ESQ.

SIR,—The second promised communication from Professor Boeck has now arrived, and the interest of the individual case which led to the present correspondence becomes in a great measure merged in the subject of syphilisation generally.

M. Ricord believed, as Boeck now believes, that all syphilitic sores may be artificially inoculated; and that they would all alike, when thus inoculated, produce a "specific pustule".

In 1855, M. Clerc announced the doctrine that the indurated chancre could not be inoculated upon a syphilitic person. In 1856, I published some cases illustrating the correctness of this view.

In 1858, M. Fournier published the results of 100 cases in which he had attempted to inoculate the secretion from an indurated sore. He succeeded in two instances only. Subsequently, M. Rollet published an account of 200 cases in which he succeeded in producing the specific pustule in six per cent.; and he accounts for these cases by supposing that they were instances of mixed chancres—i. e., cases in which there had been a twofold inoculation, and in which the poison of an indurated sore had become mixed with the secretion from a soft or suppurating sore.

In the forty-fourth volume of the *Medico-Chirurgi-*

cal Transactions, I have shown that both primary and secondary indurated sores, which usually yield no inoculable secretion, may, when artificially irritated, produce an inoculable pus; and that the secretion of an indurated sore, retained in the presence of an irritating fluid, may in like manner become inoculable upon a syphilitic person. (See Cases II and III.) The inoculations produced in this way differ, however, materially from those produced from the secretion of an ordinary suppurating sore. They are more superficial; they are not attended with any loss of substance; and they do not leave any cicatrices.

If, then, the secretion from an indurated sore cannot, as a rule, be inoculated, and the artificially or accidentally produced suppurative action can, is it not likely that it is this induced action, and not the original disease, which is reproduced? The seed should be known by its fruit. The indurated sore, when inoculated, should produce an indurated sore; the suppurating sore, a suppurating sore. But here we have an action produced which differs in some respects from both of these; and the important question at once suggests itself: Is this action the true syphilitic disease? or does it more resemble the phagedænic or the sloughing actions which may be induced on real syphilitic sores, and which may be communicated to other parts without themselves partaking of the nature of syphilis?

Now, we are informed that Professor Boeck finds it necessary, in order to obtain an inoculable pus from indurated chancres, to confine their secretions by means of dry lint. If this process be necessary in order to obtain an inoculable secretion, it is evident that it is not the natural action alone which is inoculated. It is the adventitious artificial action which is propagated; and we must inquire how far the original disease is modified or altered by this process.

When the secretion of a suppurating sore is placed on an indurated chancre, as has so often been done by Rollet, a fluid is obtained which may be inoculated again upon the patient; but the result is exactly the same as if the secretion of the suppurating sore alone had been used. A soft sore is produced; and the inoculated part takes no cognisance of the infecting action. Now, how fares it with the pus that has been subject to Professor Boeck's process? The professor himself tells us.

In the year 1856, Dr. Boeck syphilised a patient suffering from chronic eczema, and who had never had constitutional syphilis. Five years afterwards, M. Bidekap, at Dr. Boeck's request, inoculated this patient again with the secretion from a characteristic indurated chancre. Pustules were produced, which were followed by very superficial ulcerations; these very soon cicatrised, and were followed by no induration, and by no secondary symptoms.

How very different are the results of the direct inoculation of the secretion of an indurated sore in other hands, Dr. Boeck has, with characteristic honesty, also informed us. M. Danielssen syphilised a great number of lepers. No constitutional syphilis appeared in any of these, with one exception. In this case, two hundred and eighty-seven artificial inoculations had been performed with the secretion of soft sores from the 25th of April, 1857, to the middle of September following; when, on the 28th of September, he was inoculated by M. Danielssen, with a positive result, from an indurated sore. In the beginning of February 1858, the patient had distinct constitutional syphilitic symptoms.

In Professor Boeck's hands (*Recherches sur la Syphilis*, par W. Boeck; Christiania, 1862, pp. 68b, 68c), the secretion from an indurated sore produced only superficial ulcerations, without induration, and not followed by any secondary symptoms. In M.

Danielssen's hands, on the contrary, the same process was followed by large indurated ulcers, followed by constitutional syphilis.

From these facts it would appear that, by Professor Boeck's process, the action of the syphilitic poison is in some way modified or destroyed. Its sting is gone. For the much dreaded syphilitic inoculation, a very innocent and harmless treatment is substituted.

In the year 1861, I performed a considerable number of experiments with the secretion of indurated sores that had been made to suppurate either accidentally or artificially; and I found that the results produced were exactly similar to those which Professor Boeck now describes. Tolerably large, rather irregular pustules, were produced. Some of these are represented in the forty-fourth volume of the *Medico-Chirurgical Transactions* (Plate ix, Figs. 5, 6, and 7).

It thus appears that three very different actions have been included under the term syphilisation; and, until these actions are distinguished, the confusion which has hitherto reigned with regard to this subject will continue.

1. There is the inoculation of real syphilis in a constitution not previously affected.

2. The inoculation of the secretion of the soft or suppurating sore.

3. The inoculation of the accidental or artificial suppurative action induced upon an indurated sore.

The first of these (to which the name "syphilisation" ought, in my opinion, exclusively to belong) is so serious a matter, that, if likely to be at all generally practised, it would probably at once be prohibited by law.

2. Although a much less formidable proceeding, the repeated inoculation of the secretion of the soft or suppurating sore has led to many grave inconveniences. To this process apply the remarks of a writer in the *British and Foreign Medical Review* for January 1865. "Woe be to the wretch who falls into the hands of a believer in syphilisation! We had occasion to see several times, both in Paris and Vienna, patients who had been thus treated, and whose arms, back, chest, and legs were pitted with innumerable cicatrices; nor shall we easily forget one 'misérable,' who lay with an enormous phagedænic sore, involving the whole of one buttock and the upper part of the thigh—a consequence of inoculation. This syphilisation, or indefinite multiplication of simple sores by inoculation, and therefore no syphilisation at all, has been tried at Vienna, as elsewhere on the continent, and with the anticipated result—complete failure to cure syphilis, or to prevent its recurrence."

3. The inoculation of the artificially induced suppurative action from an indurated sore would appear, in Professor Boeck's hands, a very mild and innocent proceeding; and I have certainly, in my limited experience, never seen any evil results from this practice. If syphilisation by this method were confined to those who had acquired syphilis, there would, I apprehend, be no great objection to its use. But, even in Professor Boeck's hands, its results are far from encouraging, when used for the treatment of children hereditarily affected. Out of forty-two children treated in this way, twenty-two died! This is a rate of mortality to which we, fortunately, have no parallel in this country, under the ordinary mode of treatment. The fact remains to be explained, how it is that Professor Boeck's mode of syphilisation, which I believe to be accompanied by no danger when applied to persons who have acquired syphilis, should in his hands produce such insignificant results when applied to those who are not syphilitic.

In concluding this part of the subject, I may be

allowed to state that, however much some surgeons may have the misfortune to differ from Professor Boeck with regard to the conclusions at which he has arrived, there can, I apprehend, be no difference of opinion in the profession with regard to the accuracy of his records or the honesty of his intentions. His great work, published at the expense of the Government, bears upon it the impress of thorough truthfulness.

In reference to the case which originally called forth the present correspondence, I would observe, that I could readily conceive a mild form of syphilis in a person who paid no attention to the condition of his skin, or in one who was previously in some degree under the influence of the disease, or in a patient where some other action supervened so as to mask the symptoms; in which the secondary manifestations might for a time be overlooked; but I cannot conceive it possible that in the case in question, seen by so many eminent men, a disease could have been acquired which remained dormant, without giving any signs of its existence, during a period of six years, and then for the first time showed itself with such terrible severity. Such a case, if substantiated, would, I believe, be unique in the annals of medical science. When this patient was under my care, he had an enlargement of the left parietal bone extending over the space of several square inches. The bone appeared uniformly thickened, very hard, and without any soft or depressed portion such as usually exists in similar affections having a syphilitic origin. There was also a deep-seated persistent enlargement of some of the deep-seated tissues on the back and left side of the neck (perhaps connected with the vertebræ), giving the appearance, at first sight, of an unusual development of the muscles in this situation.

I am, etc., HENRY LEE.

9, Savile Row, April 11th, 1865.

OVARIOTOMY: CLAY'S ADHESION CLAM.

LETTER FROM JOHN CLAY, ESQ.

SIR,—In the abstract of Mr. Baker Brown's admirable paper "On a New Method of Securing the Pedicle in Ovariectomy," read before the Fellows of the Obstetric Society in February last, Mr. Brown is reported to have said: "Having repeatedly used the actual cautery of late, employing Dr. Clay's instruments, etc." In the same paper the name of Dr. Clay of Manchester is more than once mentioned in reference to the procedures of the operation; and the inference to be drawn from the above quotation is, that the instruments used by Mr. Brown were some devised by Dr. Clay of Manchester. As I was not aware at the time of reading the report that Dr. Clay had devised any instrument to be used as an actual cautery, or that he agreed with that mode of securing the pedicle or dividing the adhesions in the operation of ovariectomy, I addressed a note to Mr. Baker Brown, requesting to be informed whose the instruments were which he employed, and he kindly sent me a reply, of which the following is a copy. I regret to learn that my note was not answered earlier in consequence of Mr. Brown's indisposition.

"17, Connaught Square, Hyde Park, W.

"My dear Sir,—I have been prevented by illness from replying to your note before this. I certainly spoke of *your* clam as Mr. Clay's; the word 'Dr.' is a typical error entirely. Ever since you first introduced your clam to the profession I have used it, and seldom or ever use any ligatures; and as you see, I even use the clam, or rather an improvement on yours, to secure the pedicle.

"As you are fairly entitled to all the credit due to

the clam, you are perfectly at liberty to make any use of this note you choose.

"Ever yours sincerely, I. B. BROWN.
"To John Clay, Esq., Birmingham."

I may be allowed to add that I am the more anxious that this explanation should be publicly made, as the instruments have been considered by an eminent ovariotomist unfitted for the purpose for which they were invented. I may state, however, that the gentleman referred to heated the cauterising iron in boiling water, which was a perversion of the application of the instruments which I never contemplated. The instrument heated by the flame of a spirit lamp, has never failed in my hands in severing the adhesions and effectually preventing any hæmorrhage.

From experiments which I have recently made, I find that the cauterising iron requires to be heated to about 800° Fahr. To attain this uniform temperature with ease and accuracy, I find that this may be accomplished by immersing the iron in a metal bath composed of one part each of lead and zinc melted in a suitable iron ladle. The iron when immersed in the metal is apt to become coated with it, which is of little importance in the operation, having no injurious effects on the structures to be divided. This coating of metal, if desired, can be removed by subjecting the iron to a greater heat than that of the metal bath.

Mr. Brown merits every acknowledgment for the skill and courage he has evinced in employing the actual cautery for securing the pedicle in ovariotomy—a mode of procedure which has opened a new era in the performance of this important operation.

I am, etc., JOHN CLAY,
Professor of Midwifery, Queen's College, Birmingham.
April 1865.

POOR-LAW MEDICAL REFORM.

LETTER FROM WILLIAM DATE, ESQ.

SIR,—Will you allow me a small space in your JOURNAL to throw out a suggestion upon the subject of Poor-law Medical Reform.

Mr. Griffin in your issue of March 25th, says: "If, however, the Poor-law Board still continue obdurate, we must, like the lawyers, become politicians, and at the next general election refuse to give a vote without a promise that each member will aid in obtaining from Parliament an equitable adjustment of the claims of the Poor-law medical officers."

Now, sir, I beg leave respectfully to differ from Mr. Griffin; I think that the profession will not gain much in this respect by becoming politicians. It is not often that an election is so closely contested that a candidate would care to gain one—or half a dozen—votes by making such a promise. Even if he did, we know from experience that the M.P. generally finds it convenient to forget the promises made by the candidate.

I do not think, then, that we are likely to gain any assistance from Parliament. The fact is that M.P.s and the public generally look upon the subject in a very commercial spirit. The present value of a commodity is regulated by the relative proportions of supply and demand. The supply of medical officers far exceeds the demand, and therefore their services are cheap. It is not, perhaps, exactly this course of reasoning which is followed, but the same result is roughly obtained by the question—"If the appointments are underpaid and not worth having, why do you take them?" No later than last week, in the debate on the Superannuation Bill, we find members of Parliament asserting that medical men do not take Poor-law appointments for the sake of the salary, but for the prestige attaching to them.

It is certain that, as long as medical union officers can be found at the present salaries, Boards of Guardians are not likely to raise their rate of payment. The remedy, then, for the present state of things lies in our own hands, and in ours alone. Would the profession generally "strike," and each member refuse to accept a union appointment except under certain conditions previously agreed on, Boards of Guardians, Poor-law Board or Parliament would soon raise the present pitiable scale of payment. I would then, with all respect, suggest to Mr. Griffin that, instead of spending more money in memorials to Parliament or the Poor-law Board, he should take steps to obtain from the profession an unanimous agreement as to the minimum terms at which Poor-law appointments should be taken by medical practitioners. He might put the question to each member of the profession individually—"If all your brethren agree to do the same, will you decline a union appointment, except under such and such conditions?"

I am aware that the present holders of union appointments might fear that, after the object of the "strike" had been obtained, others than themselves might, in the scramble, obtain the appointments which they had previously given up. I think this objection might be obviated if every medical man not at present holding a union appointment, would promise not to oppose the present holder at the first election after the rise of salary had been obtained.

I cannot help thinking that, some such plan as the one which I have very roughly sketched is feasible, if only some energetic man like Mr. Griffin would start it and carry it out.

I am, etc., WILLIAM DATE.
Ilkestone, April 4th, 1865.

POOR-LAW MEDICAL RELIEF.

LETTER FROM R. GRIFFIN, ESQ.

SIR,—I shall feel obliged by your giving insertion to the annexed circular from the Poor-law Board to the Boards of Guardians, as it is a document of very considerable importance.

I should recommend the medical officers of each union to meet, and, if possible, come to some definite decision as to what should be considered "expensive medicines". Cod-liver oil and quinine are named, and, in addition to these, I should say leeches, opium, castor-oil, sarsaparilla, and perhaps a few other drugs might be added, but not too many, lest all should be rejected.

It may fairly be pointed out to the Guardians that the recommendation of the select Committee was made for the benefit of the poor, as it was considered, that in consequence of the expensive nature of many articles, and the very low salaries paid to the medical officers, they could not always afford to purchase them, and as a consequence, the poor have not had them to any very great extent; therefore, to attempt to reduce any of the salaries cannot be submitted to by the medical officers. Should any of the Boards of Guardians be disposed to find all the medicines for the poor, I should recommend the medical officers to second the proposal and submit to a general revision of their salaries.

I am, etc., RICHARD GRIFFIN.
12, Royal Terrace, Weymouth, 15th April, 1865.

The following circular letter on the above subject has been addressed by the Poor-law Board to Boards of Guardians:—

Poor-Law Board, Whitehall, S.W., 12th April, 1865.

SIR,—I am directed by the Poor-law Board to state that they are desirous of drawing the attention of the

Guardians to the question of the supply of medicines for the sick poor.

The Board transmitted to the Guardians a copy of the report of the Committee of the House of Commons on poor relief shortly after it was printed, with the view of informing them of the opinions and recommendations of the Committee on the several points to which their inquiries had been directed.

The Board think it right, however, now to bring more particularly under the notice of the Guardians the following resolution of the Committee relating to medical relief, viz.:—

"That there are no sufficient grounds for materially interfering with the present system of medical relief, which was made the subject of special and lengthened inquiries by select Committees of this house in the years 1844 and 1854.

"That the recommendations of those Committees were for the most part carried out by the orders of the Poor-law Board, and the system of medical relief appears to be administered with general advantage. Your Committee, however, recommend that in future cod-liver oil, quinine, and other expensive medicines, shall be provided at the expense of the Guardians, subject to the orders and regulations of the Poor-law Board."

The Board have repeatedly considered the recommendation of the Committee relative to the supply of cod-liver oil, quinine, and other expensive medicines, with the view of determining what measure should be taken by them to carry it into effect.

It does not appear to the Board that they can, with advantage, issue any general and positive regulation on the subject; and the Board are of opinion that much difficulty and embarrassment might arise from a compulsory interference with the arrangements for medical relief, which are in force under the existing contracts. They request the Guardians, however, to be good enough to consider whether an alteration in those arrangements as regards the supply of the medicines referred to cannot be effected whenever a new appointment of a medical officer is made, or, with the consent of the present medical officers, during the continuance of their existing contracts.

With regard to the mode in which the proposed object can most conveniently be effected, the Board are of opinion:—

1. That it may be advisable to provide a store of cod-liver oil at the workhouse, or at some other convenient places of deposit in the union, and to supply it to the sick poor on the prescription of the medical officers, through the relieving officers, in the same way as wine or other extras recommended by the medical officers in the way of nourishment are now supplied.

2. That quinine and other expensive medicines may be supplied, either by an order of the medical officer on a chemist, the cost of the medicines so ordered being paid for by the Guardians to such chemist as goods or provisions supplied in relief; or by the medical officers themselves, who may send in an account quarterly to the Guardians of the cost of the medicines in question which they may have supplied to their pauper patients.

The former plan may probably be convenient in the town unions; the latter in the country unions.

Cod-liver oil and any other medicines intended to be so supplied should be specified and excepted from the provisions of the medical contract, which require generally that medical officers should themselves provide the requisite medicines and medical appliances for their pauper patients.

I am, etc.,

(Signed) ENFIELD, Secretary.

Medical News.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND. The following gentlemen have been elected Fellows of this College.

Cruise, Francis Richard, M.D.T.C.D.

Haughton, the Rev. Samuel, M.D.T.C.D.

APPOINTMENTS.

*ARMSTRONG, J. C., Esq., elected Surgeon to the Gravesend and Milton Infirmary and Dispensary, in the room of Dr. Sanders, resigned.

BENNETT, George J., Esq., appointed Honorary Surgeon to the Gateshead Dispensary.

*SOPER, William, Esq., appointed Surgeon to the Jews' Hospital, Lower Norwood.

ARMY.

BARRY, Surgeon D. P., Military Train, to be Staff-Surgeon, *vice* T. R. Williams, M.B.

FINEGAN, Staff-Assistant-Surgeon B. J., to be Assistant-Surgeon 2nd Foot, *vice* F. M. Chalk.

HEDLEY, Staff-Assistant-Surgeon W. S., M.D., to be Assistant-Surgeon 1st Foot, *vice* W. White.

Low, Staff-Assistant-Surgeon E. L., M.B., to be Assistant-Surgeon Military Train.

MACBETH, Surgeon A. M., Military Train, to be Staff-Surgeon, *vice* W. Y. Jeeves.

MACFADIN, Assistant-Surgeon F. H., 73rd Foot, to be Assistant-Surgeon Military Train.

MENZIES, Surgeon R., Military Train, to be Staff-Surgeon, *vice* D. Woods.

MILLER, Surgeon O. B., Military Train, to be Staff-Surgeon, *vice* J. Hannan.

OWEN, Staff-Assistant-Surgeon O., to be Assistant-Surgeon 50th Foot, *vice* G. F. Davis.

PRICE, Staff-Assistant-Surgeon W. S., M.D., to be Assistant-Surgeon 73rd Foot, *vice* F. H. Macfadin.

STOREY, Staff-Assistant-Surgeon R., to be Assistant-Surgeon Military Train.

WHITE, Assistant-Surgeon W., 1st Foot, to be Assistant-Surgeon Military Train.

To be Staff-Assistant-Surgeons:—

MILITIA.

WALTER, Assistant-Surg. J., Kent Artillery Militia, to be Surgeon.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.= Rifle Volunteers):—

GAYE, H. S., Esq., to be Honorary Assistant-Surgeon 10th Devonshire R.V.

BIRTHS.

CLARKE. On April 9th, at Mold, Flintshire, the wife of *Edward G. Clarke, Esq., of a daughter.

CRISP. On April 6th, at Lacock, Wilts, the wife of *J. H. Crisp, Esq., of a son.

DEATH.

STEPHENSON. At Nottingham, aged 29, Annie, wife of *T. Appleby Stephenson, Esq.

THE ENDOSCOPE. At a meeting of the Surgical Society, held on the 7th inst., Dr. Fleming of the Richmond Hospital exhibited Desormeaux's endoscope, and detailed some experiments which he had made with it. The experiments had already been made familiar to the profession by Dr. Cruise.

SANITARY STATE OF BOURNEMOUTH. Mr. Hawkesley has been called in by the local commissioners at Bournemouth to investigate and report upon the sanitary state of the town in respect to drainage. This wise proceeding will probably lead to a settlement of the differences which have lately agitated the inhabitants of that naturally health-giving place.

TYPHUS IN AUSTRALIA. Several cases of typhus fever occurred at Melbourne in the month preceding the departure of the last mail for England. The *Melbourne Argus* states that all the cases are traceable to the ship *Golden Empire* and to the premature release of that vessel from quarantine. Several ships which reached Victoria in the month were placed in quarantine on their arrival.

SUPPRESSION OF QUACKERY. No quack is permitted to practise in France. When a man is about to commence the practice of medicine in any town there, he is obliged to present to the mayor, or other authority of the town, his diplomas, and if they are not *en règle*, he is not allowed to open his practice. Why cannot that which is done in France be done in England? (*Solicitors' Journal*.)

THE CASE OF DR. PRITCHARD. The completed report of the analysis by Dr. MacLagan of the stomach and viscera of the late Mrs. Pritchard and Mrs. Taylor was received by the Glasgow authorities on Saturday. The report is one of great length, describing the various processes gone through in the course of both the qualitative and the quantitative analysis. The result of the whole is an inference, well supported by the statements in the report, that not only Mrs. Pritchard but Mrs. Taylor were poisoned by antimony. With reference to Mrs. Taylor, although the poison has not been found in such large quantities as in the body of Mrs. Pritchard, yet distinct traces of it have been discovered in the blood and intestines, and in the stomach alone as much as a quarter of a grain has been found. It is supposed that the unfortunate lady had received minute doses several times, and that her final death-blow, so to speak, had been given in the administration of a large dose about three or four hours before her decease. (*North British Mail*.)

BIRTHS, DEATHS, AND MARRIAGES IN SCOTLAND. The seventh annual report of the Registrar-General has just been issued. The report is for the year 1861. The state of elementary education, the report says, continues satisfactory. Year after year it appears that as many women are able to sign their names in the marriage register in Scotland as men in England. Under the head of marriages it is stated, as the result of statistical investigation that the married women of Scotland are more prolific than those of England, seeing that, during the year 1861, every 314 wives at the child-bearing ages gave birth to 100 children in Scotland; whereas it required 355 wives

at the same ages for every 100 births in England. As like results appear year after year, it may be assumed as proved that the Scottish married female is more prolific than the English married female. The Registrar-General also directs attention to an inquiry made for the first time into the comparative mortality of the married and the unmarried women at each quinquennial period of life. The results arrived at, he says, are startling, and particularly merit the attention of those engaged in life assurance.

THE LLEWELLYN MEMORIAL. The memorial to the memory of David Herbert Llewellyn, late surgeon of the Confederate *Alabama*, was last week erected in the parish church, Easton, Wilts. It may be remembered that this gallant man refused to imperil the safety of the wounded when the *Alabama* was sinking by taking a seat in the boat with them, and went down with the ship amid the balls of the Federal *Kearsage*. The east window, of Gothic architecture, in the perpendicular style, is filled with stained glass, the centre compartment representing the birth of Christ, and the Crucifixion, with the Ascension in the quatrefoil. The side lights have figure subjects; the Good Samaritan, Christ walking on the water to save the sinking Apostle Peter, Christ healing the sick, the Apostles at the Beautiful Gate of the Temple, and Faith, Hope, and Charity in the tracery. The monument consists of a handsome black marble slab of pyramidal form, upon which is placed a Latin cross in white marble, of prominent size; at the foot rests a naval anchor and cable, with shot of varying sizes. Leaning against the side of the cross is the wand of Æsculapius, and beneath an entablature with the inscription. (*Wiltshire Independent*.)

VOLUNTEER HOSPITAL. The only serious casualty that occurred during the Brighton Review was from the wheels of a gun-carriage passing over the thigh of a gunner, not breaking, but bruising it very badly. The poor fellow was at once conveyed in one of the Netley ambulances from the field to the temporary hospital, where he was attended to by Brigade-Surgeon Burrows, of the 1st Sussex Artillery. This little hospital is very neat and airy. It contains four beds, an operating-table, and all the appliances necessary in surgical cases of emergency. In addition there were four accident beds provided at Bevendean Farm, and a ward to accommodate thirty or forty cases was secured in the Industrial Schools. Brigade-Surgeon Burrows had charge of these arrangements, which were altogether exclusive of those in the general hospital of the town. Two of the men of the Carbineers had falls from their horses. One soon recovered from the shock he received in falling, and was able to mount again. The horse trampled on the knee of the other soldier and hurt it, but even in this case the injury is believed not to be a serious one.

DR. JOHN STEARNE, FOUNDER AND FIRST PRESIDENT OF THE COLLEGE OF PHYSICIANS IN IRELAND. Dr. Stearne was born in 1624 at Ardbraccan, in the county of Meath. The family to which he belonged has numbered amongst its members many distinguished men, among whom were Archbishop Ussher and the author of *Tristram Shandy*. His career at Trinity College was interrupted by the rebellion, and to save his life he fled to England, where he completed his studies, first at Cambridge and afterwards at Oxford. His life at Cambridge he describes as one of peculiar quiet and felicity, and avows that he would not exchange it for the riches of the kings of the Persians. On his return to Ireland, he was, in 1656, elected Hebrew lecturer; but he resigned both it and all his college preferments. Stearne, besides being a man of extensive erudition and great mental

powers, was a time-server and a diplomatist, and his acute and sagacious mind foresaw the approaching downfall of the Cromwellian party, and the deprivation and ejection of all who had been appointed to offices of emolument during the Commonwealth. On the recall of Charles II in 1660, the entire of the fellowships conferred during the interregnum were pronounced illegal; but so skilfully had Stearne trimmed his course to the changing current, that he was appointed by King's letter to one of the vacant senior fellowships, with a special exemption from the statute of celibacy. He would appear at this time to have enjoyed extensive practice. An entry in the College books records the fact of the Board having passed a resolution permitting him to absent himself from the College at night "in consideration of his practice of physick." One grand effect of Stearne's exertions was the founding of a "hall for the sole and proper use of physicians". Stearne was its first President. He procured a charter for the new College in 1667. Stearne continued President until his death in 1669. On purely medical subjects he wrote little; but one of his works contains a code of sanitary rules in which he descants on the advantages of cold baths, air, exercise, etc., with "Aphorisms on Felicity", wherein he lays down regulations for the guidance of life—e.g., "That a man must be a time-server"; "A man who lendeth money to a friend oftentimes loseth both friend and money". He recommends his reader never to oppose himself to the *vox populi*; for it will in most cases overwhelm him who opposes it; but if it be yielded to, it will in a short time consume itself and burn out. He tells a curious story of "a case which came under his own observation." A young man had been successfully operated upon for stone in the bladder. The calculus was all in one piece, and weighed eleven ounces, yet the wound healed without suture or plasters. The patient's father, who was present at the operation, was so violently affected by the fear of his son's death, that within twenty-four hours every hair of his head fell off. He afterwards complained of great heat in his head, became for two hours deprived of vision, and lo! his hair began to bud forth again! It was not customary for physicians of the time to write medical treatises. They studied and observed much, but wrote little; and when they did write it was frequently on subjects unconnected with medicine, and addressed to literati rather than to physicians, who had not yet emancipated themselves from belief in the infallibility of Hippocrates. Moreover, the spirit of the age was intensely theological. Stearne was an Admirable Crichton in his way. He excelled as a scholar and as a physician, and equally so as a theologian in an intensely theological age. His character has been well summed up in these words, which form part of his epitaph outside the chapel of Trinity College, Dublin. "*Philosophus, medicus, summusque theologus idem.*" (Dr. Belcher in *Dublin Med. Press.*)

TO CORRESPONDENTS.

. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

The length of Report of Proceedings of the Medical Council must be our apology with our correspondents, the publication of whose letters, etc., have been in consequence necessarily delayed.

THE RUSSIAN EPIDEMIC.—It was remarked last week in the French Academy of Medicine, that there had been evidently great exaggeration in the newspaper accounts of the epidemic in Russia. Several academicians said that they had just received letters from St. Petersburg, in which no reference whatever was made to the so-called "pestilence". Moreover, nothing had been received on the subject from French consular agents in Russia.

CHANGE OF TYPE IN DISEASE.—E. L. writes: "I have heard a physician of long standing in London say, that he could remember the time when there were as many as 90 per cent. of the patients in Westminster Hospital who had ague. A case is now rarely heard of in the hospital. According to Dr. Barclay, therefore, we should conclude that a change in the type of disease has taken place; but the profession generally will, I have no doubt, attribute the fact to its evident cause—viz., the drainage of the once marshy land on either side of the Thames about and above Westminster Bridge."

ANIMAL FOOD FOR INVALIDS.—SIR: In the JOURNAL for this week (No. 224), mention is made of the great waste caused by giving animal food to the sick in the form of beef-tea. The chief reason for the practice is, no doubt, that the sick can often take liquid food, and no other; but for more than two years, I have found the following formula very useful—convalescent patients enjoying the food so prepared, and deriving benefit from it.

Take chicken, or the lean of veal or beef; mince it as fine as sausage-meat; make a gravy with the bones; and, having added some finely grated bread, a little butter, salt, and pepper, flavour with an onion or sweet herbs.

Pour the mass thus prepared into tin cups, capable of containing two or three ounces, cover them with paper, and steam them for half an hour. I am, etc.,

April 14th, 1865. J. C. COOKWORTHY.

THE GRIFFIN TESTIMONIAL FUND.—SIR: The following subscription has been further received on behalf of the above Fund:—Richard Wilding, Esq. (Church Stretton), 5s. 3d.

Amount previously announced, £132:15:0.

I am, etc.,

ROBERT FOWLER, M.D.,

Treasurer and Hon. Sec.

145, Bishopsgate Street Without, April 20th, 1865.

Observations

ON THE

CÆSAREAN SECTION AND ON OTHER OBSTETRIC OPERATIONS.

BY

THOMAS RADFORD, M.D.,

F.R.C.P. EDIN. AND F.R.C.S. ENG., ETC.,
HONORARY CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL,
MANCHESTER.

CHAPTER X.

Considerations on the Cæsarean Section as an Operation of Election.

IN the preceding remarks, I have to my own mind most satisfactorily proved that the Cæsarean section is at least an operation of necessity, and that those measures which have been proposed as substitutes are totally inadequate to supersede it.

The (British) statistics of this operation are most certainly unfavourable; yet it has, I think, been shewn that the great cause of the maternal mortality is avoidable; and that most of the other alleged causes of this fatality have been pointed out to be subject to control, and that some of them are really preventable, whilst others are remediable.

Although the deaths of the women from this operation, as hitherto performed, are very numerous, yet objections ought not to be raised against it on data so unsatisfactory as those are which now influence the opinions of British practitioners. When I speak of unsatisfactory data, I mean that we should not take an abstract view of them, and attach to them more importance than they deserve. British obstetricians have been guided more from prejudice arising from preconceived opinions, than from an analysis of the real causes of death in these cases.

A comparative estimate of the mortality between this operation and craniotomy has never been fairly made. As regards the Cæsarean section, all the deaths are known, whereas those of craniotomy are only very partially known. This latter operation is not confined to any particular class of cases, but it is performed under very different circumstances and dangers—in some cases of accidents which occur in labours, such as hæmorrhage, convulsion, and other contingent mischief, which happen in women whose constitutional powers are unimpaired; whilst the greater part of the women who have undergone the Cæsarean section have laboured under incurable disease, and have had additional injury inflicted upon them by protraction, and in many cases by the practitioner in his ineffectual performance of craniotomy, etc.

Dr. Joseph Clarke reports 49 cases of craniotomy, in which 16 mothers died, or one in three. Dr. Collins performed craniotomy in 79 cases, in which 15 died, or one in five. Now, in Dr. Clarke's practice collectively, there are recorded 65 deaths;* in Dr. Collins's practice collectively, there are recorded 94 deaths.* Thus the statistics of craniotomy, which are indiscriminately made up of all kinds of cases in which it has been performed, show an unfavourable result.

Besides this, we have no account of the injuries

which are inflicted on the pelvic organs by the instrument used in this operation.

In 77 cases of Cæsarean section, there were collectively 98 deaths,* the greater portion of which were not due to the operation; but, on the contrary, very many lives might have been saved, if it had been timely and judiciously performed.

Notwithstanding all the preëxisting dangers in Cæsarean cases, several recoveries have taken place. These favourable terminations ought to encourage us to hope, and indeed ought to inspire us with confidence, that if the operation were earlier performed, and on a different class of subjects, it would be attended with infinitely more success.

These cases prove that, notwithstanding the serious nature of the constitutional disease which existed in these women, the vital powers were equal to the reparation of both the abdominal and uterine incisions; and also show the fallacy of the opinion that wounds of the uterus are necessarily mortal. The conservative vital powers were wonderfully apparent in the case of Mrs. Sankey, which is related in the *London Medical Gazette*, also in the *Provincial Medical and Surgical Journal*. The restorative powers in this individual were really so active as to impress my mind with the conviction that the chance of success would be as great in well conducted Cæsarean cases as that which attends other capital operations.

Another woman (Mrs. Haigh), in whom mollities ossium existed to a great extent, and whose pelvis was very much distorted, showed great restorative powers. She recovered, and lived several years afterwards. She died exhausted by the disease. *Post mortem* examination revealed no disease in the abdominal or pelvic viscera. The uterine tissue was uniform in appearance, there being no cicatrix to indicate the site of the incision. There was only a single band of lymph, not thicker than a thread, passing from this organ to the peritoneum; so that there existed no mechanical obstacle to the distension and ascent of the uterus, if she had unfortunately become pregnant again; but the moral rule of abstinence prevailed with both her and her husband.

Recoveries after rupture of the uterus afford further evidence that wounds of this organ are not always mortal. The lacerated tissue in these cases must be in a very different, and indeed in a much more unfavourable, condition for uniting, than in Cæsarean cases. In these accidents, the peritoneum, the abdominal and the pelvic viscera, must inevitably sustain very great injury by the escape of the infant, and also very frequently of the placenta, through the uterine rent; and also from the attempts which are made for the delivery of the woman. The same mischief cannot possibly be inflicted by a well conducted Cæsarean operation.

Two instances of recovery after rupture of the uterus have occurred in my practice. One of these women became pregnant several times afterwards. In one of these pregnancies, she went to her full time, and bore a child, which is still alive; and she also aborted several times. During her last labour, and also during the several abortive periods, she had the valuable aid and advice of my respected friend

[Continued on page 427.]

* These accounts contain the number of deaths of both women and infants.

TABLE OF RECORDED CASES OF CÆSAREAN SECTION IN GREAT BRITAIN AND IRELAND.

No.	Year.	Name and residence of the patient.	By whom and where the case is related.	Operator.	Cause of difficulty.	Duration of the labour.	Mother.		Child.		Mother survived.
							Pre-serv'd.	Died.	Pre-serv'd.	Died.	
1	Jan. 9, 1738.	Alice O'Neil, aged 33 years, near Charlemont, Ireland.	Mr. Duncan Stewart, <i>Edinburgh Essays</i> , vol. v, p. 439.	Mary Donnelly.	Not stated.	12 days.	P.			D.	
2	June, 1757.	Patterson, Cannon Gate, Edinburgh.	Smellie's <i>Midwifery</i> , vol. iii, coll. 39, No. 2, p. 373.	Mr. Smith.	Distorted pelvis, most likely from molities ossium.	7 days.		D.		D.	18 hrs.
3		Not named.	Manuscript Lectures.	Professor Young.	Distorted pelvis, from rickets.	No account.		D.	P.		
4		Not named.	Manuscript Lecture.	Professor Young.	Distorted pelvis, from moll. ossium.	No account.		D.	P.		3 days
5		Not named.	Mentioned in Dr. Hamilton's <i>Outlines of Midwifery</i> .	Mr. Alex. Wood, Edinburgh.	Not stated.	No account.		D.		D.	
6	Before 1740.	Not named, Rochdale, Lancash.	Dr. Hull's <i>Defence</i> , p. 67.	Dr. White, Manchester.	Not stated.	No account.		D.		D.	
7	Oct. 1769.	Martha Rhodes, London.	Dr. Cooper and Mr. Henry Thompson, <i>Lond. Med. Obs. and Inquiries</i> , vol. iv.	Mr. H. Thompson.	Distorted pelvis, from rickets.	Nearly 30 hours.		D.		D.	5 hours
8	1774.	Elizabeth Clerk, aged 30, Edinburgh.	Dr. Alex. Hamilton, <i>Outlines of Midwifery</i> , p. 293.	Mr. W. Chalmers, Edinburgh.	Distorted pelvis, most likely from molities ossium.	12 days.		D.	P.		26 hrs.
9	August, 1774.	Elizabeth Forster, London.	Dr. Cooper, <i>Lond. Med. Obs. and Inq.</i> , vol. v.	Mr. Hunter, London.	Distorted pelvis, from molities ossium.	60 hours.		D.	P.		25½ hrs.
10	1775.	Not named.	Dr. Hull's <i>Defence</i> , p. 66.	Mr. W. Whyte, Glasgow.	No account.	No account.		D.		D.	No account.
11	1777.	Elizabeth Hutchinson, aged 40, Leicester.	Dr. Vaughan, <i>Cases and Observations on Hydroph.</i>	Mr. Atkinson, Leicester.	Distorted pelvis, from molities ossium.	Nearly 3 days.		D.	P.		About 80 hrs.
12	Nov. 1793.	Janet Foster, aged 40, Blackrod, Lancashire.	Mr. Barlow, <i>Med. Records and Researches</i> , p. 154; also, his <i>Observations</i> , p. 355.	Mr. Barlow.	Distorted pelvis, from fracture.	5 days.	P.			D.	
13	Sept. 1794.	Isabel Redman, aged 33, Blackburn.	Dr. Hull's <i>Defence</i> , p. 172.	Dr. Hull.	Distorted pelvis, from molities ossium.	12 hours.		D.	P.		34 hrs.
14	June, 1795.	Jean Douglas, Edinburgh.	Dr. Alex. Hamilton, <i>Outlines of Midwifery</i> , p. 299.	Dr. James Hamilton, jun.	Distorted pelvis, from molities ossium.	54 hours. Spurious pains three nights previous.		D.		D.	33 hrs.
15	Sept. 1793.	Anne Lee, Manchester.	Dr. Hull's <i>Defence</i> , p. 162.	Dr. Hull.	Distorted pelvis, from rickets.	10 days.		D.		D.	6 hours
16	1798.	Janet Williamson, aged 38, Kirriemuir, Forfarshire.	Dr. Hull's <i>Defence</i> , p. 188.	Mr. Kay, Forfar.	Distorted pelvis, from molities ossium.	More than 3 days.		D.		D.	11 days
17	June, 1799.	Elizabeth Thompson, aged 32, Hazelhurst, near Ashton-under-Lyne, Lancashire.	Mr. Wm. Wood, <i>London Med. Memoirs</i> , vol. v.	Mr. Wood, Manchester.	Distorted pelvis, from molities ossium.	21 hours.		D.	P.		76 hrs.
18	March, 1800.	Not named; resided at Edinburgh.	Sir Chas. Bell, <i>Lond. Med.-Chir. Trans.</i> , vol. iv.	Mr. Jno. Bell.	Distorted pelvis, from molities ossium.	Not stated.		D.	P.		Very short time.
19	August, 1801.	Hannah Rheubotham, aged 41, Manchester.	Mr. Wm. Wood, <i>Lond. Med. Phys. Journ.</i> , vol. vi, p. 346.	Mr. W. Wood, Manchester.	Distorted pelvis, from molities ossium.	61 hours.		D.		D.*	24 hrs.
20	Feb. 1801.	Susan Holt, aged 36, Lower Shore, Rochdale, Lancashire.	Dr. Hull's <i>Translation of Baudelocque</i> , p. 134.	Mr. Walter Dunlop.	Distorted pelvis, from molities ossium.	56 hours.		D.	P.		6 days and 9 hours
21	July, 1811.	Mrs. M., Leith, Scotland.	Dr. Kellie, <i>Ed. Med. and Surg. Journal</i> , vol. viii.	Dr. Kellie.	Distorted pelvis, from molities ossium.	About 36 hours.		D.	P.		About 24 hrs.
22		Wife of Benjamin Buckley, Staley-bridge, Lancashire.	Not before mentioned.	Mr. Hutton.	Distorted pelvis, from molities ossium.	3 days.		D.		D.	
23		Name unknown; resided at Staley-bridge, Lancashire.	Not mentioned before.	Mr. Hutton.	Distorted pelvis, from molities ossium.	No account as to precise time; but long.		D.	P.		
24	August, 1811.	Wife of Jas. Tinker, aged 31, Moston, Lancashire.	Mr. K. Wood, <i>Med.-Chir. Trans.</i> , vol. vii, p. 264.	Mr. K. Wood.	Distorted pelvis, from molities ossium.	About 40 hours.		D.		D.	10 hrs.
25	Jan. 1817.	Wife of Wm. Ratcliffe, aged 35, Staley-bridge, Lancashire.	Not mentioned before.	Mr. Hutton.	Distorted pelvis, from molities ossium.	No account.		D.	P.		48 hrs.
26	July, 1817.	Ann Hacking, aged 42, Blackburn, Lancashire.	Mr. Barlow, <i>Observations</i> , p. 361.	Mr. Barlow.	Distorted pelvis, from molities ossium.	13 hours.		D.	P.		76 hrs.
27	April, 1820.	Mary Ashworth, aged 42, Denton, Lancashire.	Dr. Radford, <i>Edin. Med. & Surg. Jour.</i> , vol. xv; <i>Lond. Med. Gaz.</i> , vol. xlviii, p. 95.	Mr. Morris, Ashton.	Distorted pelvis, from molities ossium.	37 hours.		D.		D.*	35 hrs.
28	Sept. 1820.	Mrs. Lowe, aged 30, Perth, Scotland.	Dr. Henderson, <i>Ed. Med. and Surg. Jour.</i> , vol. xvii, p. 105.	Dr. Henderson.	Distorted pelvis, from molities ossium.	102 hours.		D.	P.		20 hrs.
29	April, 1821.	Wife of G. Ridgedale, aged 42, Blackburn, Lancashire.	Mr. Barlow, <i>Observations</i> , p. 375.	Mr. Barlow.	Distorted pelvis, from molities ossium.	About 34 hours.		D.	P.		52 hrs.

* Dead before operation.

TABLE OF CASES OF CÆSAREAN SECTION (continued).

No.	Year.	Name and residence of the patient.	By whom and where the case is related.	Operator.	Cause of difficulty.	Duration of the labour.	Mother.		Child.		Mother survived.
							Pre-serv'd.	Died.	Pre-serv'd.	Died.	
30	May, 1821.	Mary Nixon, aged 39, Manchester.	Dr. Radford, <i>Edin. Med. & Surg. Jour.</i> ; <i>Lond. Med. Gaz.</i> , vol. xlviii, p. 98; <i>Proc. Med. & Sur. J.</i> , vol. xv, p. 426, 1851.	Mr. Wilson.	Distorted pelvis, from mollities ossium.	22 hours.		D.	D.		67½ hrs.
31	April, 1826.	M. R., aged 22, Stobsmuir, Scotland.	Mr. Crichton, <i>Dundee, Ed. Med. and Surg. Journ.</i> , vol. xxx, p. 53.	Mr. Crichton.	Distorted pelvis, from fracture, etc.	6 days.		D.	P.		8 hours.
32	August, 1826.	Mary Forrest, aged 35, three miles from Blackburn, Lancash.	Mr. Barlow, <i>Lond. Med. & Surg. Jour.</i> , vol. iv.	Mr. Barlow.	Distorted pelvis, from mollities ossium.	From 30 to 36 hours.		D.	P.		More than 3 days.
33	Sept. 1829.	Mrs. M., aged 26, Belfast.	Communicated by Dr. W. Campbell, <i>Edin. Med. & Surg. Jour.</i> , v. xxxv, p. 351.	Dr. McKibbin.	Distorted pelvis, from a large exostosis arising from the sacrum.	About 30 hours.		D.	D.†		17 hrs.
34	Nov. 1834.	Mrs. — Dublin.	Dr. Montgomery, <i>Dublin Med. Journ.</i> , vol. vi.	Mr. Porter.	Fibrous tumour, growing from substance of uterus and covered by peritoneum.	18 to 20 hours.		D.	D.†		21½ hrs.
35	April, 1834.	Mary Bamford, aged 38, Great Easton, Rockingham.	Mr. T. I. Greaves, <i>Lancet</i> , vol. ii, 1833-4.	Mr. Greaves.	Distorted pelvis, from mollities ossium.	About 34 hours.	P.		P.		
36	May, 1835.	Sarah Bate, aged 36, Birmingham.	Mr. Knowles, <i>Trans. Proc. Med. Assoc.</i> , vol. iv, p. 376.	Mr. Knowles.	Distorted pelvis, from mollities ossium.	About 30 hours.	P.		P.		
37	Aug. 14, 1840.	Mary Ann Jones, aged 39, Manchester.	Mr. Jas. Whitehead, <i>Med. Gaz.</i> , vol. xxviii, p. 939, 1840-41.	Mr. Whitehead.	Distorted pelvis, from mollities ossium.	24 hours; in active labour for 2 to 3 hours.	P.		P.		32 days 10 hrs.
38		Name not given, or age; private note, aged 30.	Mr. Dendy, Medical Society of London, <i>Lancet</i> , 1842-43, vol. xliii, p. 691.	Mr. Bryant, Lambeth.	Distorted pelvis, by rickets.	24 hours.		D.	P.		60 hrs.
39	Oct. 17, 1842.	Mary Davis, aged 23, Reading.	Mr. T. B. Hooper, <i>Reading Medical Society, Lancet</i> , 1843, vol. xliii, p. 689.	Mr. Hooper.	A large tumour, arising from the sacrum.	3 days.		D.	D.†		40 hrs.
40	Mar. 8, 1842.	Mary Jepson, aged 43, a weaver, Darwen.	Mr. S. H. Wraith, <i>Darwen, Proc. Med. Jour.</i> , vol. v, p. 329, 1842-43.	Mr. Wraith.	Distorted pelvis, from malacosteon.	10 hours.		D.	D.		3 hours.
41	Feb. 22, 1843.	Mary Forrest, aged 38, a weaver, Stockport.	Dr. Radford, <i>Med. Gazette</i> , vol. xlvii, p. 801; <i>Proc. Med. & Sur. J.</i> , vol. xv, p. 257, 1851.	Dr. Radford.	Distorted pelvis, from malacosteon.	53 hours.		D.	D.		About 27 hrs.
42	July, 1825.	Betty Wilcock, aged nearly 49.	Messrs. Hardy and Bailey, <i>Ass. Med. J.</i> , vol. iv, p. 45, 1850.	Mr. Bailey.	Distorted pelvis, from mollities ossium.	83 hours.		D.	P.*		61½ hrs.
43	Oct. 18, 1837.	E. Hull, aged 25, Sunderland.	Mr. J. Ward, <i>Lond. Med. Gazette</i> , vol. xxi, p. 817.	Mr. J. Ward.	Distorted pelvis, from (presumed) rickets.	27 to 30 hours.		D.	D.†		5 days 7½ hrs.
44	1840.	..	Dr. Churchill's <i>Operative Midwifery</i> , Table, p. 205, communicated in a letter to Dr. C.	Dr. Elliott, Waterford, Ireland.	Distortion of pelvis; kind not mentioned.			D.	D.		
45	Feb. 1842.	Helen McKenzie, aged 35.	Mr. Alex. Ross, <i>London and Edin. Monthly Journal</i> , vol. ii, p. 425.	Mr. A. Ross, Invergordon.	Distortion of pelvis, most probably mollities ossium (outlet contracted). Tubercles of ischia approximated very closely; coccyx closing up lower part.	Midwife stated she had been in labour, more or less, for 12 days. Much time elapsed after Mr. Ross decided on necessity of operation.	D.		P.		5 days 7 hrs.
46	August, 1844.	Rebecca Brooks, aged 27, Welford.	Mr. Fred. Cox, <i>Proc. Med. and Surg. Journal</i> , vol. viii, p. 382.	Mr. F. Cox, Welford.	Distortion of pelvis, most likely rickets, but not stated.	30 to 40 hours.		D.	D.†		54 hrs.
47	Feb. 21, 1845.	Wife of Richard Instan, aged 40.	Mr. J. Milman Coley, Pamphlet.	Mr. Coley.	Distortion of pelvis, said to be rickets.	At least 10 days.		D.	D.		9 days.
48	March, 1845.	Mrs. R., Shettlestone.	Mr. William Lyon, <i>Lond. & Edin. Jour. of Med. Science</i> , vol. v, p. 885.	Mr. Lyon.	A large tumour, the size of a child's head.	72 hours.		D.	P.		36 hrs.
49	Nov. 1845.	Mrs. Sankey, aged 41, Salford.	Dr. Radford, <i>Lond. Med. Gaz.</i> , vol. xlvii, p. 894; <i>Proc. Med. & Sur. J.</i> , vol. xv, p. 313, 1851.	Mr. Goodman, assisted by Dr. Radford.	Distortion of pelvis, from mollities ossium.	12 to 14 hours.	P.		P.		Lived.
50	Jan. 1847.	Sarah Bartlett, aged 37, removed for operation to St. Bartholomew's Hospital, London.	<i>Lancet</i> , 1847, vol. i, p. 139.	Mr. Skey, London.	Distortion, from rickets.	5 hrs. 5 min.		D.	P.		36 hrs.

* Two.

† Dead before operation.

‡ Craniotomy.

TABLE OF CASES OF CÆSAREAN SECTION (continued).

No.	Year.	Name and residence of the patient.	By whom and where the case is related.	Operator.	Cause of difficulty.	Duration of the labour.	Mother.		Child.		Mother survived.
							Pre-serv'd.	Died.	Pre-serv'd.	Died.	
51	June, 1847.	Mrs. Toft, aged 30.	Dr. Radford, <i>Lond. Med. Gazette</i> , vol. xlviii, p. 238; <i>Prov. Med. & Surg. J.</i> , vol. xv, p. 483, 1851.	Mr. Jas. Brind, Manchester.	Distorted pelvis, from molities ossium.	3 days, and 10 to 12 hours.		D.		D.*	5½ hrs.
52	1849.	Mrs. Rogers, aged 40, six miles from Lisburn, in a mountainous district.	Mr. Jno. Campbell, <i>Lisburn, Ir.-land</i> , <i>Lond. Med. Gazette</i> , vol. xliii, p. 1105.	Mr. Campbell.	Distorted pelvis, from molities ossium. Clearly so, from the account of the case.	52 hours.		D.	P.		7 days.
53	May, 1849.	Mary Haigh, aged 31, near Ashton-under-Lyne.	Dr. Radford. Read at Worcester, at meeting of Prov. Med. Assoc., Aug. 1, 1849. <i>Prov. Med. & Surg. J.</i> , afterwards in <i>Lond. Med. Gaz.</i> , vol. xlvii, p. 1110.	Mr. Cluley, assisted by Dr. Radford.	Distorted pelvis, from molities ossium.	Slight pains for two or three days. Membranes unruptured until a few hours before operation.	P.		P.		
54	May, 1850.	Elizabeth Williams, in the 27th year of her age.	Dr. Chas. West, <i>Med.-Chir. Trans.</i> , vol. xxxiv, p. 61.	Mr. Skey.	Distorted pelvis, from molities ossium.	16 hours.		D.	P.		108½ hrs.
55	May, 1850.	Mrs. Kennaway, aged 43.	Mr. M. Nimmo, <i>Dundee, Mon. Jour. Med. Science</i> , Sept. 1850, p. 226.	Mr. Nimmo.	Distorted pelvis, from molities ossium.	5 days. Occasional pains; but had regular labour for 17½ hours.		D.	P.		Scarcely 3 hrs.
56	Sept. 1850.	Sarah — Bethnal Green, aged 23.	Dr. Henry Oldham, London, <i>Med.-Chir. Trans.</i> , vol. xxxiv, p. 89.	Mr. Poland, London.	Distortion of the pelvis from rickets.	84 hours from the time labour was artificially induced.		D.		D.†	About 44 hrs.
57	June, 1851.	Sarah L., aged 23.	Dr. Henry Oldham, <i>Guy's Hosp. Reports</i> , vol. vii, p. 426.	Mr. Poland.	Cancer of the cervix uteri.	Indefinite slight uterine contractions for 2 or 3 days. Membranes ruptured about 12 hours before operation.	P.		P.		Recovered from.
58	Nov. 1851.	Ann Kenyon, aged 31.	Dr. Broughton, manuscript.	Dr. Broughton, Preston, assisted by Dr. Radford and Dr. Whitehead.	Distorted pelvis, from molities ossium.	11 hours.		D.	P.		5 days 2 hrs.
59	1853.	Aged 41.	Dr. Charles Waller, <i>Medical Times and Gazette</i> , vol. vi, p. 266.	Mr. Le Gros Clark.	Large fibrous tumour.	30 hours. Membranes ruptured 78 hours before operation.		D.	P.		36 hrs.
60	Feb. 28, 1853.	Mrs. Y., Shaftesbury, Dorset, aged 42.	Mr. R. W. Sanneman, <i>Chelsea, Lancet</i> , vol. ii, 1850, p. 50.	Mr. Sauneman.	Distortion of the pelvis, from molities ossium.	12 hours.		D.	D.		23 hrs.
61	June 24, 1854.	Mrs. — Cupar, Scotland.	Professor Simpson, <i>Assoc. Med. Jour.</i> , vol. ii, 1854, p. 1066.	Professor Simpson.	Distortion of the pelvis, from molities ossium.	60 or 70 hours.		D.		D.‡	
62	1854.	Mary A. Johnson, aged 31.	Paper read at Royal Med. & Chir. Soc., April 13, 1858; from notes kindly furnished by Dr. Greenhalgh to me.	Dr. Greenhalgh.	Distortion of the pelvis, from molities ossium.	About 6 hours.		D.	P.		3 weeks.
63	1854.	Lydia Lowdey.	Notes kindly furnished me by Dr. Greenhalgh.	Dr. Greenhalgh.	Distortion of the pelvis, from rickets.	12 hours.		D.	P.		4 days.
64	Dec. 5, 1854.	Martha C., Nottingham.	Dr. J. C. L. Marsh, <i>Lancet</i> , vol. ii, 1853, p. 560.	Dr. Marsh.	Distortion of the pelvis, from molities ossium.	55½ hours.		D.	P.		48 hrs.
65	Feb. 29, 1856.	Mrs. Runham, Lawton, aged 30.	Mr. Humphry, <i>Assoc. Med. Jour.</i> , vol. iv, 1856, p. 779.	Mr. Humphry.	Distortion of the pelvis, from molities ossium.	Not definitely stated; but most likely about 30 hours.		D.		D.‡	20 hrs.
66	Feb. 25, 1856.	Nancy Nixon, aged 27, a travelling hawker, in a miserably low cellar, Staleybridge, Lancash.	Dr. Chas. Clay, <i>Midland Quarterly Journal of the Medical Sciences</i> , part i, p. 21.	Dr. Clay.	A large tumour of a firm fibro-cartilaginous texture.	3 days.		D.		D.‡	19 days.
67	Oct. 1, 1856.	Anne N.	Dr. W. H. Thornton, <i>Lancet</i> , vol. i, 1857, p. 313.	Dr. Thornton.	A bony projection from promontory of sacrum, evidently exostosis; perhaps cellulated.	About 18 hours.	P.			D.*	
68	Feb. 19, 1858.	Matilda T., aged 20, Newport, Monmouthshire.	Mr. Jas. Hawkins, <i>Lancet</i> , vol. i, 1858, p. 529.	Mr. Hawkins.	Distortion of pelvis; kind of deformity not stated; but as lameness and inability to walk in early life, it was most probably from rickets.	Not definitely stated.	P.		P.		Lived.

* Dead before operation.

† Embryotomy had begun; the arm removed.

‡ Head perforated.

§ Alive when extracted; but died in a few seconds.

† Living; died soon after.

TABLE OF CASES OF CÆSAREAN SECTION (concluded).

No.	Year.	Name and residence of the patient.	By whom and where the case is related.	Operator.	Cause of difficulty.	Duration of the labour.	Mother.		Child.		Mother survived.

* Turning ineffectually attempted. Craniotomy was also unsuccessfully performed.

† Dead before operation.

Mr. Hunt. Many years afterwards, she died in the Manchester Workhouse. Her body was inspected by Mr. Hunt, in the presence of Dr. Francis and of myself. There was not the slightest trace of the cicatrix in the womb to be seen; but there was a band of slight adhesion to the ilium.

I was consulted by Dr. Clay in his first case of large ovarian tumour, and attended along with him both before, during, and after the operation. I take this opportunity of saying I consider the successful issue of this operation as the commencement of a new era in the history of ovariectomy. It had not been attempted for many years before; and, at the time of its performance, it did not stand as if it were a recognised surgical operation. I attended also along with Dr. Clay many of his next succeeding cases, being present at all the operations. I took great interest in these cases, not only on account of that which necessarily belonged to them, but also because the results analogically tended to substantiate my views relative to the probable success of the Cæsarean section. It is nevertheless true, that the influence in these two classes of cases is not quite the same; yet there is, however, sufficient similarity between them to lead us to trust more in abdominal surgery. In ovariectomy, there is certainly no uterine incision; but there is a necessary division to be made of the connecting tissue which exists between the tumour and the uterus. In many of these cases, extensive adhesions, which exist between the tumour and the peritoneum, etc., have to be separated. It

is, however, evident that during the progressive development of an ovarian tumour, the sympathy of the peritoneum, etc., must in some measure be blunted, and consequently its susceptibility to mechanical injury must be diminished.

The rest of Dr. Clay's successful cases, and likewise those of Mr. Spencer Wells, and all those which have occurred to other practitioners, collectively afford strong evidence of the safety of abdominal incision.

The operations performed by my esteemed friend Dr. Blundell on animals, to prove some important physiological facts, likewise afford substantial evidence that abdominal wounds are very much safer than has been usually considered.

In my introductory remarks, I stated that I should not bring forward any statistical data, as shown from the result of foreign cases of the Cæsarean section, although I feel quite sure that the comparative position of this operation has been damaged by the omission. Continental success in this operation has been remarkably great, when compared with the results of British practice. There have been many instances of two or three successful operations on the same woman.

Having, as I sincerely hope, faithfully and candidly placed all the circumstances appertaining to the two operations—the Cæsarean section and craniotomy—before the profession, it now only remains for me to bring forward my proposition, first made in 1843. Deep reflection since that period, and a

strong sense of humanity, have induced me further to declare that the Cæsaræan section should be generally performed as an operation of election; and that craniotomy should be as far as possible abolished, and ought only to be performed as an operation of necessity, except (as already adverted to) in a very few cases.* I am quite aware that many of the opinions I have so urgently stated in the foregoing remarks are at variance with those of the profession generally; yet they have been most conscientiously advocated. They originated from the dictates of humanity, to try to extinguish as far as possible that dreadful expedient—nay, shall I not call it murderous operation?—craniotomy.

Having now fully and without the least reserve put my views into the hands of the profession, I consider I am only doing justice to myself in declaring that I shall not feel called upon to enter into any controversial defence of them.

Original Communications.

ON PUERPERAL FEVER.

By T. SNOW BECK, M.D. Lond., F.R.S., Member of the Royal College of Physicians, London.

[Read before the Obstetrical Society of London, February 1st, 1865.]

IN July 1860, I attended Mrs. B. in her first confinement. She had been married about twelve months, was 24 years of age, of rather short stature and good conformation, had always enjoyed good health, and during her pregnancy "never suffered any inconvenience".

On July 24th, she complained of frequent pains in the stomach, which prevented her procuring rest; but without any vaginal discharge. The orifice of the uterus was soft and open, so as to admit the end of the finger.

The following day, the pains were more frequent and of longer duration, became more distressing to her, and were complained of as of a forcing character, chiefly seated in the bottom of the back—the sacrum. The orifice of the uterus was dilated to the size of a five-shilling piece; the membranes entire. There was no vaginal discharge.

The pains continued much the same during the night, but became more decided, retaining their former character, on the afternoon of the 26th. The head descended into the pelvis, and remained stationary for some hours. Ergot of rye and borax were administered without advantage. She became much fatigued. The small forceps was introduced, and a small living female child readily extracted, without any perceptible laceration of the perineum.

Ergot of rye and borax were again given, but without producing any perceptible effect. The placenta was removed by gentle traction on the cord, combined with pressure on the abdomen. Some hæmorrhage followed; and, after it had continued about an hour, I introduced the hand, and found a large, flabby, open uterus, which could not be distinguished through the walls of the abdomen, and which remained inert under the combined influence of the hand internally and pressure externally on the abdomen. Ice was now passed up into the orifice of the uterus, when a slow and languid contraction followed—sufficient to prevent further hæmorrhage, but not sufficient to induce a firm contracted organ. I

reluctantly desisted from further efforts in this direction, by reason of the repeated solicitations of her friends.

She passed a good night; and the succeeding day—the 27th—was so well that she considered "keeping in bed was only a farce".

On the 28th, I was struck with the alteration in her expression, which was anxious and somewhat pinched. The complexion bore a thick muddy hue; she complained of feeling inwardly cold, but had no decided shivering; the pulse was 110, soft, and otherwise natural; the skin cool, and moistened with perspiration, which had a peculiar acrid odour. She complained of pain in the left lumbar region, which extended round the abdomen in a line with the crest of the pubic bone, and induced considerable difficulty in turning in bed. The walls of the abdomen were tender in these situations; the lochia not much in amount, and rather offensive; no milk had appeared in the breasts; there were no after-pains; no vomiting; the bowels had not been relieved. A dose of calomel and opium was given, and followed by a gentle saline aperient.

July 29th. A strong, faint, and peculiar offensive odour pervaded the room. The skin was soft, and freely perspiring, which imbued the night-dress with moisture, whilst the exhalation from it appeared to hang about the bed. The expression was anxious and depressed; no pain in the head; mental faculties appeared perfect; no delirium; feeling of great exhaustion; tongue clean and red; not much thirst; she had occasionally vomited a little froth, slightly tinged with yellow; the bowels were moved several times, the motions being liquid and very offensive; the urine was apparently natural; pulse from 120 to 130, small, and easily compressed. The pain in the side was relieved, and she could turn in bed with more ease; but a more general soreness existed over the whole abdomen on deep pressure, particularly around the navel and over the hypogastrium. The walls of the abdomen were also tender to gentle pressure. The calomel and opium were continued every four hours, combined with a stimulating diaphoretic mixture, and turpentine fomentations were applied to the abdomen.

July 30th. The odour in the room had nearly disappeared; the offensive odour of the lochia was also gone. She expressed herself as being better. The expression of the face was improved, but still oppressed; and the complexion muddy. The perspiration was much diminished; the pulse from 130 to 140, weak, and very easily compressed; the tongue clean; no great thirst. She continued to vomit a little froth occasionally; did not complain of pain in the abdomen, unless under firm pressure, when the tenderness was about the same. The walls of the abdomen were more prominent and tympanitic on percussion. The mental faculties were unimpaired.

In the evening, I met Dr. Murphy in consultation, who took a most unfavourable view of the case, although the symptoms continued slightly improved. Camphor and opium, in pills, were directed to be substituted for the former pills; and the other remedies to be continued.

On the following morning—July 31st—she was evidently sinking. In the night, she had vomited some coffee-grounds looking matter upon the pillow, and had slightly wandered in her sleep; was lying on the left side; breathing sighing; could not be roused to consciousness; vomited occasionally on the pillow; the pulse very rapid, and fluttering.

She gradually sank, and died about noon.

The vomited matters, under the microscope, showed many fat-globules and portions of muscular fibre. The black points were composed of a congeries of

* See remarks, page 344.

jointed fibres, resembling the yeast-plant, which, when aggregated together, produced the black colour.

I could not prevail upon the friends to allow an examination of the body, and consequently had not an opportunity for ascertaining whether any, and, if any, what local changes had taken place during this fatal illness, the symptoms and course of which seemed to preclude the idea that it arose from inflammatory action, and appeared to point to the occurrence of some poisonous infection of the whole system. Hence the question arose: By what means could this infection have taken place?

I had attended the lady's family for several years, and herself at different times for slight illnesses; and I thus had an opportunity of knowing that her health was good and her constitution sound. This was, moreover, indicated by the excellent health she enjoyed during the whole of her pregnancy, and the expression of her own feelings the day after the birth of the child, that "keeping in bed was only a farce". The following day, however, evidences of poisoning of the general system were noticed; and this proved of so serious a nature as to cause her death three days after the first symptoms were observed.

The leading feature in the case was the absence of that contractile power in the uterus necessary to effect the expulsion of the child and provide for the safety of the mother after its birth. This was apparent at each step of the labour—the languid contraction of the uterus; the inability to increase the force of these contractions by the usual agents; the requirement for the use of the forceps; the necessity for the removal of the placenta; the hæmorrhage which followed; the existence of a large, flabby, open uterus, when the hand was introduced; the great difficulty to induce sufficient contraction of the organ to prevent further hæmorrhage; and the impossibility to procure a firm persistent contraction after the cessation of the hæmorrhage. These facts impressed me with the conviction that the poisonous infection of the general system, which showed itself on the second day after delivery, had occurred in consequence of this lax condition of the uterus, which permitted the uterine sinuses to remain pervious; and that this condition arose from the absence of that due contraction of the muscular tissue of the organ which is essential to prevent any fluids from circulating along their canals. From the observation of previous cases, I was assured that the cessation of the hæmorrhage could not be taken as an indication that the amount of contraction had occurred which is necessary to effectually prevent the passage of fluids from the interior of the uterus into the general venous system. But no opportunity occurred for testing the correctness of these opinions, until I met with the following case.

On March 21st, 1864, I was requested to see Sarah H., from whose mother I received the following history.

She was a strong, healthy young woman, 28 years of age; had been married a few years, and was delivered, in her third pregnancy, on the 14th. During her first pregnancy, she was attacked with small-pox, and miscarried with twins. In her second pregnancy, she went the full period, and had again twins, one child being dead, the other living. During her last pregnancy, she was quite well until the night previous to her confinement, when she suffered some pains, but was in "strong pains" for two hours only prior to the birth of the child, which took place before the arrival of the medical attendant. The placenta came away about half an hour afterwards, "without any pain".

She had but few after-pains. The lochia were very much, and of a black red colour." All things

appeared to progress well until early in the morning of the third day (16th), when she was taken "heart-sick, with the head and body full of pain." She vomited some offensive dark coloured matter. The bowels were moved twice, the motions being very copious and very offensive. She had taken castor-oil the same morning. She had no appetite.

Nothing was done for these symptoms, which continued for two days; they then became easier, and "she appeared to be doing nicely". But, early in the morning of the sixth day—the 19th—she awoke saying, "Oh! what shall I do? I think I am dying; I never felt such a feeling in my life." The bowels were relieved into the bed; the motions being watery, very offensive, and accompanied with much flatus. She again vomited some offensive dark coloured matter; was very thirsty; had no appetite; "had little dozes, but had never seemed to sleep since her confinement."

She took some Dover's powder, and the sickness appeared to abate. But, about noon on the seventh day—the 20th—the sickness and purging returned. She also complained much of the pain in the abdomen; and "the perspiration used to stream off the forehead from it." She also complained of "being so weak she did not seem to have strength to move her hands."

The symptoms continued much the same; and I saw her on the morning of the eighth day—the 21st. She was lying on her back, with the head low, the knees drawn up and apart. She complained of a feeling of so much exhaustion and sinking, "as if she would sink through the bed," and "as if she had not power to lift the hand to her head." The expression was anxious; the complexion pale and muddy; the skin cool, or rather cold, with a slight moisture on the surface, but not perspiring; the breathing frequent and short; the pulse about 140, small, soft, and very compressible; the abdomen somewhat distended and tympanitic on percussion. She did not complain of pain; but, in answer to questions, said she had occasional shooting pains across the upper part of the abdomen. The abdomen was very tender to superficial, as well as to deep and continued pressure. The lips were dry and parched; the tongue large, dry, and dark coloured. There was great and incessant thirst, followed by constant vomiting of whatever was taken; the vomited matter was "sometimes quite green." The motions, which were said to be watery and not very offensive, were passed every few minutes into the bed. The urine was also passed into the bed. The lochia said to be sufficiently free, of good colour, and not offensive. There was no pain in the head; and the intellect was quick, clear, and very anxious. She was directed to take some iced brandy and water, with a stimulating astringent mixture.

In the evening, the symptoms were slightly changed. She was talking constantly, yet answered all questions readily and correctly. The skin was warmer—a slight perspiration on the surface; the eye bright; the face less pale. The vomiting and purging continued unabated. She was lying on the back, frequently moving the arms and legs. In reply to questions, she said she was in no pain. The pulse was very quick and fluttering.

She gradually sank, and died about 2 A.M. on the ninth day—the 22nd.

The body was examined thirty-six hours after death. It was well developed, moderately fat. Some port-wine coloured fluid escaped from the mouth. The abdomen was distended and tympanitic. The uterus could not be felt, nor any tumour through the walls of the abdomen. Some slight green discoloration existed in the left iliac region; also some reddish

discoloration in lines, marking the course of some veins on the abdomen and thighs. There was considerable fat in the walls of the abdomen. The small and large intestines were much distended with flatus; there was no unpleasant odour. The omentum was considerably injected; the small intestines were somewhat injected at their contiguous edges. About two pints of opaque, dirty, yellowish, and oily looking serum were found in the cavity of the abdomen, in which floated numerous shreds of loose friable lymph. The whole of the peritoneum was slightly injected, and the surface covered with a thin layer of soft friable recent lymph, rather thicker in some places. The mucous membrane of the small and large intestines was pale; they were much distended with air. There was a small amount of feces in the descending colon. The fimbriated extremities of the Fallopian tubes were of dark, almost black colour, from great injection. The uterus was large, spongy to the feel, round, and even, occupying the hollow of the sacrum; its surface was somewhat injected. The liver was apparently healthy. The kidneys were also healthy; their capsules were thin and transparent. The veins of the pelvis were not distended; and, on dividing them, the blood was fluid, thin, and of a brownish red colour. No coagula were observed.

The uterus was removed for further examination. It was round, pear-shaped, even on the surface, soft and rather flabby to the touch. It measured five inches across the fundus, five inches and three-fourths in length. The walls of the body were one inch and one-tenth thick, eight-tenths of an inch at the neck, six-tenths at the fundus, and at one part not more than four-tenths of an inch. The cavity was large, three inches and three-fourths at the fundus, five and a half inches longitudinally; and was every where covered with a dark brownish red mucous discharge, which was readily removed, leaving a smooth, uniform, and slightly red surface beneath, studded over with those small depressions, about one-tenth of an inch in diameter, which are caused by the decussation of the internal layer of muscular fibres. The situation of the placenta was marked by an oval and less red patch on the anterior surface of the body. The neck of the uterus was of a deep, approaching to a black colour, which appeared to arise from blood effused into the tissues. The upper portion of the vagina was of similar character, but not so deep. The line of separation between the mucous membrane of the uterus and that of the vagina was distinctly marked. The secretion on the surface of the uterus was of a mucous character, and loaded with round ovate, and in some instances spindle-shaped bodies (elementary corpuscles), comparatively few blood-discs, some mucus-corpuscles, many fat-globules, and a few columnar epithelium-cells.

When placed under water, the inner surface of the uterus was seen to be every where covered with a soft membrane, from which numerous shreds proceeded, and floated in the water. This membrane consisted chiefly of the round or ovate bodies found in the mucous secretion (elementary corpuscles), amorphous connective tissue, and contractile fibre-cells. The portion marking the former attachment of the placenta was thicker, and appeared as if a thin layer of that body was left adhering to the uterus. It contained several (what appeared to be) small coagula of blood, and consisted of elements similar to those already noticed, with some fibrous tissue.

At this part of the uterine surface, numerous open orifices were observed, which, when pressed, emitted a minute portion of their fluid blood, and which led directly to sinuses of considerable size beneath. Air blown into the uterine and spermatic veins escaped out of those orifices, and ascended through the water;

and water injected into the same veins readily escaped into the uterine cavity.

There was not any appearance of inflammatory product in any part of the uterus. The veins were empty; their walls not injected; their surface smooth and shining. The lining membrane of the sinuses was clear and shining, and the connecting tissue beneath healthy. The lymphatics were also empty and transparent. The muscular tissue was undergoing the usual amount of fatty degeneration, but otherwise appeared unchanged from that of healthy tissue.

In this case, the labour appears to have been natural, and the placenta was expelled without any assistance. No hæmorrhage occurred; whilst the abundant flow of the lochia and the blackened colour of the discharge were the only symptoms to indicate that the uterus was not fully contracted. Everything appeared to progress favourably until the third day after the birth of the child, when symptoms indicative of general poisoning first arose. These were not marked, and appear to have remained stationary, if not somewhat diminished, during the two following days; but, on the morning of the sixth day, they recurred with increased severity, and continued gradually to increase until death took place, early in the morning of the ninth day after the delivery. In the examination after death, extensive peritonitis, of a low type, was observed, with a copious effusion of serum, and of that soft friable lymph which characterises these cases. But, beyond this, all the tissues of the uterus were found, after careful and even minute examination with the microscope, to be perfectly healthy. No appearance of inflammatory action was any where observed; and the only condition differing from that of health was the soft flabby state of the uterus—its full size; and the important circumstance, that the uterine sinuses remained so open as to allow air blown into, and water injected into, the uterine and spermatic veins, to traverse these canals, and to escape by the open orifice on the inner surface of the organ. I think it is, then, fair to assume that, where these vessels are pervious to admit fluids to pass in a direction contrary to the course of the blood, these fluids may pass in the direction of the current of the circulation. It is even probable that the blood flowing along the large veins would produce an exhaustive effect, and thus facilitate the entrance of fluids into the uterine sinuses.

So far, then, as any deductions may be justified from these cases, they appear to show that:

1. The phenomena of puerperal fever may be produced by the introduction of poisonous fluids into the general system.
2. The uterine sinuses remaining pervious to the flow of fluids, would afford a means by which this poisonous fluid or fluids would enter the system.
3. The pervious condition of the sinuses remained, in consequence of an absence of that firm and persistent contraction of the uterus after childbirth which appears necessary to effectually close these canals and prevent all circulation of fluids along them.
4. The secretion from the interior of the uterus was probably sufficient, when mixed with the blood, to induce the effects observed; and it would further follow that:
5. The various phenomena observed in puerperal fever may arise from this cause, modified infinitely by many incidental states; and the various inflammatory actions and products observed in the course of the disease would not be the essential parts of the disease, but morbid phenomena which occurred during the course of it.

6. The primary, though not the only object, in the prevention of these attacks of puerperal fever, will then be to procure a firm, complete, and persistent contraction of the uterus after the birth of the child, and thus effectually to shut off all circulation within the vessels of this organ.

But it remains to be seen how far these conclusions accord with the results of previous observers.

[To be continued.]

CONGENITAL LUXATION OF FEMUR: NECROPSY.

By Dr. BEREND, Director of the Orthopædic Establishment at Berlin.

THE necropsy of a boy, 6 years old, suffering from congenital luxation of the femur, showed the following particulars. The acetabulum was found in its normal situation, reduced to one-third of its proper circumference; and the articular surface was almost flat, instead of concave, apparently through deficiency of the surrounding capsular ligament. The head of the femur rested in a new articulation on the outer surface of the ilium, behind and a little above the acetabulum. This new articular surface was limited posteriorly by a semi-circular bony wall which would have formed a complete acetabular cavity, if the bony ring had been a little higher and extended entirely around. The head of the bone, partially atrophied but not at all destroyed by ulceration, was turned upon its axis in such manner that the trochanter major pointed directly forwards (ante-

serted into the edge of the sacro-ischiatic notch, with no attachment to the neck of the femur, but a narrow insertion in the head of the bone itself. The rotator muscles (pyriformis, gemelli, and obturator internus) were quite as abnormally situated, being inserted into the false capsular ligament itself and not into the trochanter. Moreover, they were found to be atrophied; and, apparently as a secondary effect, to have undergone fatty degeneration. Finally, the situation of the quadratus femoris was also abnormal as to its usual insertion. This last circumstance was due to the rotation of the femur: the muscle was extended over the surface of the bone, and appeared to be rolled upon it.

ILLUSTRATIONS OF THE DIFFERENT FORMS OF INSANITY.

By W. H. O. SANKEY, M.D.Lond., Proprietor of Sandywell Park Private Asylum; Lecturer on Mental Disease in University College, London; late Medical Superintendent of the Female Department, Hanwell Asylum.

[Continued from page 294.]

OF the varieties in form of mental disease: some affect chiefly the moral and intellectual faculties, and the motor are involved in a secondary manner. Two forms, however, are more immediately connected with the motor functions; viz., general paresis, which was described in the last paper; and epileptic mania, which remains to be illustrated.

In all cases of mental disease, there is some disturbance of the motility, as shown in restless activity, or in torpidity of movement. In general paresis, the motor functions give a prominent feature to the disease. But they form the primary affection in that form called epileptic mania.

Cases of epileptic mania form some of the most formidable and trying with which the physician has to deal. The disease presents itself in two forms, according to my experience. In one, the maniacal symptoms appear to be superadded to an ordinary case of epilepsy; being, as it were, an extension of the morbid processes from the motor to the moral and intellectual faculties. In these cases, the violence is at one period very great and peculiar; being more totally uncontrollable and furious than is met with in cases of ordinary mania. The patient makes a sudden and unprovoked attack on the nearest bystander perhaps, and cannot be soothed or temporised with, as in an excitement of passion. Some of these patients direct their violence towards themselves, and will butt with their head against a wall, or will bite and tear their own flesh. It is usually on account of these outbreaks of violence that the asylum is sought; and many such cases were admitted into Hanwell during my term of office there. In all these patients, the maniacal violence gradually subsided after admission. The violence, or maniacal furor, in most of these cases, preceded each epileptic seizure; in some, however, it followed; and, in others, the fits and the violence took place together.

The second variety of epileptic mania is met with in two forms; viz., 1, with the epilepsy undeveloped; and 2, with epileptic attacks developed. The former has been described and named by my friend, Dr. Morel of Rouen, as *epilepsia larvalis*. (*Traité des Mal. Men.*, p. 480.)

It appears to be somewhat an anomaly to name an affection epilepsy, in which no epileptic seizure has yet occurred; and one cannot exactly affirm that the one condition is a premonitory or previous stage of the other; for certainly the second state is possibly,

a, Pyriformis muscle; b, Gemellus superior; c, Gemellus inferior; d, Obturator internus; e, Quadratus femoris; f, Gluteus major reflected; g, Gluteus minor reflected; h, Sciatic nerve; i, Capsular ligament; k, Head of the femur; l, Ilium; m, Os coccygis.

riously); a small portion of the original capsular ligament, arising from the anterior portion of the acetabular ring and extending over that cavity, was in-

in some cases, never developed at all. That is to say, there are cases whose phenomena correspond to the first kind, but in which the epileptic seizure is never truly present. It would remain doubtful, of course, whether epileptic seizures will become developed in these cases. The difficulty is, however, simply one of nomenclature. If we consider epilepsy a distinct disease, the anomaly remains; but viewing it simply as a symptom, the disease is equally describable, and it has characters of sufficient distinctness to separate as a form of insanity.

The following epitome of two cases well illustrate the characters of this form of disease; in both of which the epileptic seizures were dormant for a period.

CASE I. E. S. was taken up in Chelsea by a policeman for creating a disturbance. She got into a medical man's brougham which was standing at a patient's house, and vociferated to the coachman to drive on. She could only with great difficulty be dislodged from the vehicle; she resisted violently, and was taken to the station; thence to the workhouse; and, after making a great disturbance, was sent to prison. In prison, she disobeyed the rules, and was several times punished. At last, she was sent to the Asylum. On admission, she behaved well for a while; then began to encroach by making extravagant demands of indulgences; and, if refused, she broke windows, and threatened and attacked several of the female officers. She broke and destroyed with great dexterity her rooms, however strongly secured. At times, she would go a whole week without eating, etc. Her violence lasted several days when it commenced; and for several days afterwards she remained quiet, then began again to be mischievous and to plot. She was at times neat and tidy in her person; at times, filthy and disgusting.

She had no attack of epilepsy while under my observation, during about eight months. It was a case which, from the intellectual integrity and apparently wilful perversity, would be considered by many, and indeed was by several, to be merely a moral delinquency. The history of the case was, however, that up to the age of 20, she was a hard-working, industrious, and retiring person, the sister said, "the reverse of what she had become". About the age of 20, she lost her mother somewhat suddenly, and became melancholic and out of her mind, and was sent to an asylum in Ireland. She was there some time; and had several epileptic fits while there, and continued to have fits regularly for some period afterwards. The fits, in fact, had only left her shortly before she was taken insane again.

The nature of the above case would have been very obscure without the history of the attack; and, indeed, it is very doubtful whether popular diagnosis would have been in her favour had her many unruly acts brought her before a public tribunal. The patient had been very repeatedly punished while in prison, without effecting any improvement in her conduct. The next case is very similar. The subject of it had been punished by every means resorted to in prisons, and was deemed wholly incorrigible. She had been also indulged to the "top of the bent", without amelioration of her conduct. She, like the former patient, only looked upon indulgences as her right, and her corrections as great injustices.

CASE II. E. T. was left an orphan at a very early age, with £200, which was left in trust for her education. Her trustee entirely neglected her, and allowed her to play in the streets in the lowest neighbourhoods, and at last deserted her. She was taken in by a poor neighbour. At sixteen years of age, she had an illegitimate child. This was felt by her very keenly as a disgrace. She went to the workhouse, where, she

asserted, she was ill-used and unjustly treated by the master. For several years she spent her time between this workhouse and the house of correction. She was a noted character in both, on account of her violence. A great sensation was made about her by certain philanthropists; and the medical officers of the prison were requested to give an opinion about her sanity. They considered that there was no evidence of insanity in her. I was requested by the authorities also to examine her, in conjunction with Mr. Marshall of Colney Hatch Asylum. We recognised at that period the resemblance of the case to epilepsy undeveloped; and my colleague especially distinctly gave it as his opinion that the case would terminate in well-marked epilepsy. There was not, however, at that period, such an amount of proof of this, or of any mental disease, as would warrant a certificate of lunacy. We were precluded from signing a certificate by law ourselves; and we did not feel that we could recommend the officer of the prison, on our view of the case, to call the case insanity. She was, however, shortly afterwards admitted into Hanwell under my care. Her intellect probably was never very strong. Her instincts were under little control. She was in person well developed, of short and thick-set build. She endeavoured to create a morbid interest about herself; but this was prevented by the measures taken. She showed evident chagrin if not treated with more particular attention than the rest; and she endeavoured to accuse the nurses of favouritism, etc. She made several unprovoked attacks on the attendants and female officers, and required for some time great caution in treatment. The catamenia on admission were suppressed. After residence in the asylum, this function was re-established, and her conduct improved. She became industrious. She never was untruthful or dishonest. She made herself gradually very useful; and after fourteen months she left the asylum, to try to gain her own living in service. She failed in this. On several occasions, on contradiction, she threatened her mistress with violence. She at length was taken into a subordinate position as domestic in the asylum. After a very short time, she began to have regular epileptic seizures. Her disposition became perfectly altered, more quiet and subdued, but irritable on the approach of fits, when she used very foul language. Her memory became defective, mind more feeble; and she took poison (it was believed, intentionally), and died.

In this last case, there was a period of nearly ten years of riotous conduct before the evolution of epilepsy. In a similar case, which was treated in Hanwell and afterwards at Colney Hatch Asylum, the epilepsy took place after about seven years of violence.

Now, had the epilepsy *not* been developed, under what category could these cases be placed? Dr. Morel says, "epilepsia larvalis"; but it seems an anomaly to call a disease after a phenomenon which is not constant, and which may be altogether absent. The cases have sufficient characteristics to unite all, whether the epilepsy be developed or not, under one appellation. The cases are similar in character, in progress; so that the possibility of an epileptic seizure can be predicated. In fact, the epilepsy in one of the cases was prophesied three years before it occurred.

These cases form a distinct group. They are among the most violent and troublesome which we have to treat, both on account of their perversity, and on account of a certain amount of integrity of intellectual faculties which leads every one around them to deny their insanity.

My own belief is, that all these cases are closely

allied to that form of disease to which I have already alluded in a previous paper (BRITISH MEDICAL JOURNAL, Jan. 21st, 1865), under the title of Recurrent Mania. They resemble the cases there mentioned—1. In the recurrence of distinct attacks of violence, at intervals more or less regular; 2. In the violence of the paroxysmal outbreak; 3. In the somewhat rapid cessation of the symptoms and return to comparative lucid condition; 4. In the very slight permanent injury produced on the intellect; 5. In the irritability of disposition, that is constant in the intervals, frequently exhibited by accusations of unfairness or injustice towards themselves; 6. In positive denial of having acted improperly, in self-justification; and strenuous denial of having ever been insane.

Many cases exhibit all these phenomena in a more or less mild degree. There were numerous examples in Hanwell. One patient had been eleven times in Bethlehem, and two or three times in Hanwell; another had an outbreak of maniacal violence yearly, which passed off in about six weeks. In many others, chiefly old cases, the violence recurred too frequently to admit of discharge.

In some cases, the outbreak is at much more distant intervals: one or two years may intervene even.

The character of the outbreak has, however, led to a still further confusion of names. The violence is exhibited sometimes (1) towards others, (2) towards themselves, (3) toward inanimate objects, or shows itself in flagrant acts of crime. In other words, the patients may simply break out and tear their clothes, or smash furniture; they may be violent towards others, attempt to injure, to murder, to fire, burn, destroy; may commit rape, and various other enormities, in their fury. Hence have arisen the names of homicidal maniacs, pyromaniacs, etc.

The cases of this description are, fortunately, somewhat rare, and, when they occur, are usually transferred to the criminal asylums. So far as I have been able to collect evidence, it appears that the violence rarely occurs in the first attack of even these cases; that, in fact, a period of melancholy is a frequent precursor of the first attack. However, in the second and subsequent attacks, the violence is committed with but very slight warning or premonitory sign; a little and transient restlessness, or *malaise*, or depression, only being exhibited. The patient is often apparently perfectly well, quiet and harmless, and suddenly rises and attacks a bystander, and attempts to murder him. The murder having been accomplished, the patient resumes his former placid condition. But, although the kind of violence used varies—that is, it is a murder in one case, a suicide in another, or simply a destruction of property in another—it does not appear to me that such variation in the object attacked can form a basis of a classification of diseases. The whole of the phenomena, viewed together, to my mind brings these cases of *epilepsia larvalis*, homicidal mania, and cases of recurrent mania, into close pathological proximity. But by the term recurrent mania I do not include all second attacks of insanity, but only those of the peculiar type described.

[To be continued.]

CHARING CROSS HOSPITAL. A bequest of £500 has just been made to the above hospital, under the will of Major-General Sir Charles Hopkinson, of King Street, St. James's, who especially directed that his body should be opened before being placed in a coffin, and the surgeon performing the operation to receive £50.

Reviews and Notices.

FOR AND AGAINST TOBACCO; or, Tobacco in its Relations to the Health of Individuals and Communities. By B. W. RICHARDSON, M.A., M.D., Physician to the Royal Infirmary for Diseases of the Chest. Pp. 75. London: 1865.

IN this little work, Dr. RICHARDSON investigates the action of tobacco on the different organs of the body; and in the last chapter sums up his views as to the effects of tobacco generally upon the individual and upon the community at large. That smoking tobacco must be injurious to the healthy body, is a fact patent on the face of it. Tobacco is neither food nor physic; and assuredly is in no sense necessary for a healthful existence. It contains a deadly poison; and of this poison the smoker must necessarily take into his body a certain amount. Dr. Richardson says that tobacco arrests oxydation; and therefore, in the young especially, causes "impairment of growth, premature manhood, and physical degradation." He also describes the other particular injurious influences produced by it on the different organs of the body. Smoking, he, therefore, naturally adds, "is a luxury which any nation of natural habits would be better without. The luxury is not directly fatal to life; but its use conveys to the mind of the man who looks upon it calmly the unmistakeable idea of physical degradation. Why should a million of men in this country be living with stomachs that only partially digest, hearts that labour unnaturally, and blood that is not fully oxydised?" But here Dr. Richardson is necessarily met with the difficulty attaching to the use of many other luxuries; and, in fact, he admits what will be a great victory to the smoker; viz., that "of nearly every luxury it is the least injurious."

"It is" (he says) "innocuous as compared with alcohol; it does infinitely less harm than opium; it is in no sense worse than tea or sugar; and by the side of high living altogether, it contrasts most favourably. A thorough smoker never is a glutton; indeed, there is no cure for gluttony like tobacco."

This eloquent admission for tobacco will, we fear, make the reader of Dr. Richardson's pleadings *against* it very pale before the genuine smoker. And, after all, sad experience tells us only too surely that in matters of this kind mankind takes little account either of royal edicts or philosophical warnings. Neither teetotalism nor counterblast tobacco societies will put down drinking and smoking. The natural instincts of the old Adam within us lead men still on in the evil ways of irrationality. Though it were philosophically demonstrated that alcohol be not food, and tobacco only a deadly weed, yet will men go on drinking fermented liquors and smoking the dried leaves of *nicotiana* to the end of the chapter. The smoking sinner, after listening to the dreadful fulminations of an anti-tobacconist orator, and after learning all the horrible evils which await him in the end, will yet retire home to reflect upon them with his pipe in his mouth.

Of Dr. Richardson's essay, we may say that it is a calm and philosophic inquiry; and that the arguments for and against "the weed" seem fairly and candidly expressed by him. We sincerely trust that

they may have the effect of diminishing, or rather of preventing, the pernicious habit of extreme indulgence in tobacco-smoking.

In conclusion, we would remark, that we are much surprised to find Dr. Richardson writing down sugar as a substance equally injurious to the human body with tobacco. "It (tobacco) is in no sense worse than tea or sugar." One other error we would also call attention to. Dr. Richardson is, we conclude, no smoker himself, or he would assuredly never have stated that the smoke which the smoker draws from his cigar or pipe passes into his lungs. The fact is, that only a practised smoker—one whose aerial tubes are well macadamised to the funes of tobacco—can take them into his lungs. In ordinary smoking, the smoke passes into the mouth only. Consequently, no fair analogous conclusions can be drawn as to the effects induced by tobacco-smoke upon animals, who are made to breathe the smoke, to take it into their very lungs, and to bring it in contact with their highly and rapidly absorbing surfaces.

STATISTICAL TABLES OF PATIENTS IN ST. BARTHOLOMEW'S HOSPITAL DURING 1864. By G. N. EDWARDS, M.D., and A. WILLETT. London: 1865.

THESE tables contain a very full, detailed, and no doubt accurate, account of the diseases treated in St. Bartholomew's Hospital during 1864. There were admitted 5543 new patients, 553 remaining from the previous year; 4324 were discharged cured and relieved, 300 unrelieved, 315 for other reasons; and 617 died. Fifty patients died in the medical, and 38 in the surgical wards, within twenty-four hours after admission; 21 were brought in dead. The number of beds in the hospital is 650.

ON INTRATHORACIC CANCER. Part I. Introductory and Historic Sketch. By JOHN COCKLE, M.D., Physician to the Royal Free Hospital. London: 1865.

DR. COCKLE has, in pamphlet form, published the first part of his researches concerning intrathoracic cancer. In this part, he gives an introductory and historic sketch of the subject. The disease is rarely met with. Dr. Cockle, therefore, desires to put together, for the benefit of the profession, the general facts, so far as they may be gathered from a summary of authentic details. Dr. Cockle treats the subject, we need hardly add, with his usual industry and scientific skill.

MEDICAL EDUCATION AND THE PUBLIC SERVICES. I have been told by one of the examiners of a department of the public service, on whose judgment I have implicit reliance, that, as a rule, the candidates who appear before him have no accurate knowledge of any of the subjects of examination. I know that the ablest and best students do not enter the public service; they devote themselves to the service of the public in another way. I know, too, that much the larger part of the candidates in question are not educated in London. During five years, since the 1st of October 1859, the new men supplied to the Army Medical Service from different parts of the kingdom, numbered as follows:—From Ireland, 230; from England, 115; and from Scotland, 85. Those from Ireland have rapidly increased in later years. (Mr. Quain *On Medical Education*.)

WE beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, APRIL 29TH, 1865.

THE COLLEGE OF PHYSICIANS AND THE ARMY AND NAVY MEDICAL OFFICERS.

ON the 21st inst., the London College of Physicians, in our opinion, made a very great mistake, and did a great act of injustice both to itself and our army and navy medical brethren. It refused to hold out a hand of sympathy to the medical officers of the army and navy. Some months ago, the College appointed a Committee, consisting of six of its Fellows—viz., the Senior Censor, Dr. Gavin Milroy, Dr. Sibson, Dr. A. P. Stewart, Dr. Armstrong, and Dr. Markham—to inquire into the condition of the army and navy medical officers, and to report thereon to the College. The Committee set conscientiously to the work. They made themselves thoroughly masters of the whole question; they obtained information of the most positive and authentic kind; they unanimously satisfied themselves as to the truth of the grievances complained of by the army and navy medical officers; and, after several months of inquiry, they drew up, with great care and precision, a most accurate detail and history of the wrongs to which those officers have been and are at this moment subjected. But such a report, so drawn up, and so authenticated by the testimony and signatures of the Committee, was rejected by the College; and not only was it rejected, but the College, as then constituted, refused to accept it even in any modified or altered form. The College refused to say one word or do one single act which might, in the opinion of its Committee, assist in removing the grievances under which our army and navy medical brethren at this moment suffer. Such a total repudiation of its own Committee's Report is a very rare and exceptional proceeding. It is well, therefore, that the profession should know the reasons, or rather we should say the excuses, alleged for the non-acceptance of the Report.

Now we may observe, in the first place, that the facts stated in the Report were admitted to be true; that is to say, not one single one of them bearing upon the question was either upset or even attacked. The Committee, indeed, defied even the best informed and most ardent supporters of the Horse

Guards to contradict one single statement contained in the Report. Anything like reasonable grounds for the rejection of the Report were not even suggested. Indeed, it soon became evident that on this occasion the College met to record a vote, not to argue the merits of the question on which the vote was to be taken. They were told by one gentleman, who entered the army some forty-five years ago, that he had there passed many happy days, and had never felt the inconveniences mentioned in the Report. He was always consulted by his colonel on matters sanitary; and his friends were of the same opinion as himself. He never heard any complaints from the best men in the army. Besides, the College had nothing to do with army men; so why need it trouble itself about them? Then, again, it was said that the causes of discontent, as stated in the Report, were frivolous; that the College would only injure the army and navy medical men by taking up their cause; that, to be sure, it was a great mistake that the Horse Guards touched the warrant of 1858, but then ever since that time they had been continually removing the causes of discontent; that the College would be put in a false position by taking up the Report; that it was no use ripping up old grievances; and, besides, the language of the Report was too strong, and might injure the delicate susceptibilities of high officials; that, no doubt, some injustice had been done to the medical department, but then the injustice has been gradually removed.

To all this it was answered by the Committee, that the army and navy medical officers were, by their very position, unable to help themselves; that with them complaint was regarded as insubordination; that the Committee had carefully and conscientiously made themselves masters of the case, and had learnt beyond any kind of doubt that the medical officers were subjected to serious grievances; that the College was bound to help all classes of our medical brethren; and to pretend, because only a few licentiates of the College were in the army and navy, that therefore the College need take no thought for them, was a selfish idea, utterly inconsistent with the modern aspirations of the College; that not one single statement made in the Report had been controverted, or even argued upon. The Committee further argued, that to say that action taken on the part of the College would injure the medical officers, was a statement refuted by memorable facts; that, in truth, the grievances lately removed, of which the opposers of the Report and the supporters of the Horse Guards made so much, were removed in consequence of, and since, the serious action taken by the *British Medical Association*—proving thereby that the department know how to yield to pressure from without; that the restoration of the rights of medical officers in respect of forage, baggage, of servants, as regards branding,

etc., was wrung from the officials by the intervention of the British Medical Association, and of other medical bodies; that the interference of the College, therefore, would also of necessity operate to the advantage of medical officers; that all the objections made to the Report were of a mere verbal character, so much so that the Committee were perfectly ready to yield every word objected to in it, inasmuch as the real facts of the case would still remain there, true and unanswered; that to say there was no discontent in the army was simply a denial of patent and positive facts; that the warmest official defender of the Horse Guards dare not venture to say that discontent, great and universal, did not exist in the army and navy; that the Committee, who had now for many months studied this question, ought at least to have something like reason shown why their Report should be rejected; that they, at all events, must have full knowledge of the subject; that they had no object in view but to learn the truth of the case, and to act upon it; that they had no official ties to clog them—no superiors to gratify or to dread; and that they desired one sole thing, to help in doing an act of justice to the medical officers of the army and navy.

Again, the members of the Committee represented that those gentlemen, on the contrary, who especially represented the official military authorities within the College were, by their own admission, placed in a very difficult position; that their words and freedom of expression were necessarily fettered by the ties of official life: and that, therefore, their judgment and opinion could not be accepted as unbiassed and unprejudiced; that, most assuredly, those gentlemen who represented the Horse Guards represented an authority which was felt and declared by the army medical officers to be one which had no sympathy with them, and no care to remove their grievances; that for the College, therefore, to accept the opinion and advice of such an authority, was to accept the opinion and advice of those who, in the opinion of the Committee, were the very obstructives and hindrances to the welfare and elevation of the standing of the army medical officers; that when the College appointed a Committee, and that Committee had consistently discharged its duties, it was incumbent on the College, was only respectful to the Committee, that it should, at all events, state reasons for rejecting the Committee's Report.

The College, however, thought otherwise; and, in fact, as we have said, the opposers of the Report came there to vote, not to argue. The influence of the Horse Guards was (amongst those who represented the College on the occasion) stronger than that of the Committee. The unanswerable statements in the Report were left unanswered; and the old fact was illustrated, that it is much easier to hold up a hand than to give a reason for holding it up. Whether the de-

cision of the majority in this case was a wise decision, time will show. In the meantime, we may venture to express the opinion, that the College has exhibited a strange want of moral courage; a strange want of sympathy with a large and suffering body of their medical brethren; a strange want of consistency in giving to a Committee of their body the charge of a very serious and arduous inquiry, and then utterly ignoring their labours—in refusing to accept the Report even in a modified form, or to do a single act or say a single word which might be construed into an act or word of sympathy done or said by the College in favour of our army and navy medical brethren; a strange want of harmony with its modern aspirations of being the leader of scientific medicine, and the liberal parent of all branches of the medical family.

The hopes and the eyes of the whole army and navy medical officers were fixed upon the College; and this is the answer they have received!

It is only fair to state, in conclusion, that the President of the College did not accept the assertion of the prime movers of the opposition to the Report; viz., that army and navy medical men had no grievances to complain of. On the contrary, he admitted them. He said, he begged it to be distinctly understood, that the existence of the grievances were admitted on all hands, and that he had heard no one deny them. His reasons for opposing the Report were, that he thought interference, if unsuccessful, would injure the interests of the College, as well as damage the case of the army and navy medical officers.

THE LATEST INDIAN MEDICAL WARRANT.

WHEN commenting upon the changes made by the late Indian Medical Warrant in medical service of that dependency, we stated that we were not prepared to enter into all the details necessary to obtain an exact view of the changes effected by it. It is only persons on the spot who can be fully cognisant of the advantages and disadvantages of any such new arrangements.

We have, therefore, waited until the matter could be fairly brought before the Indian public, before passing a decided judgment as to the probable effect of this Indian Medical Warrant.

Now, we regret to say, the Indian press expresses disappointment as to the future prospects of the Indian Medical Service. In *A Brief Sketch of the Past and Present Condition of the Bengal Medical Service*, a surgeon of the Bengal army sketches the condition of the Indian Medical Service, and the various alterations which have been since introduced; all, as it appears, having the tendency to lower the status and the advantages heretofore enjoyed by the

Indian medical officers. The Indian Medical Warrant of 1860 placed them in a position inferior even to that of the British medical officer serving in India, to whom the provisions of the famous British Warrant of 1858 had not been extended. The first Warrant of 1864 was received with a burst of indignation. The position of the medical officer was reduced to a degree hitherto unprecedented; for it must be remembered that the distinctive features of the Indian services, the funds, to which all had formerly been compelled to subscribe, had already been abolished, with reference to those who had entered the service after the transfer of the Indian Government to the Crown. The second warrant, embodied in Sir C. Wood's despatch of November 1864, was apparently intended to have the effect of reassuring the minds of the medical profession. It has failed, however, in its purpose, if we may judge from the deliberately pronounced opinions of those among the Indian surgeons, who are, like the author of this *brochure*, best entitled to form a judgment. He candidly acknowledges the good intentions of the authors of the warrant in some particulars, and even gives them credit, we are almost inclined to think, for benefits which they did not intend to confer; for he supposes that they acknowledge the propriety of giving staff salaries to those who hold independent medical charges, as is the case with the great body of the military officers. We shall be glad to find that he is right in this particular. We concur with him in approval of the appointment of a definite time for promotion to the grade of surgeon; and we trust that the time which is necessary to qualify for a retiring pension may be allowed to include the usual furloughs in the so-called "service in India."

But the shortcomings of the dispatch are glaring. The chief disadvantages under which the service may now be said to suffer are: First, the removal of all the military European charges from the Indian into the hands of the British medical officers. For this change the Secretary for India is not responsible. This will abstract the principal prizes of the Indian Service from the regimental medical officers, who will also be debarred from the opportunities of distinguishing themselves on active service to the same extent as before; and it seems that the surgeons in charge of native regiments are to be paid on an inadequate scale. Secondly, it was hoped that a higher scale of pension would be established for length of service; the present, now that there are to be no medical retiring funds, is inadequate; and the pensions for those who are invalided for wounds or ill-health are not at present adjusted, as they are in the Royal Service. Thirdly, as the Secretary of State directs the employment of as many civil medical men as possible, many of the best prizes of the service, such as the various staff-appointments in the presidency towns, etc., will be thrown out of the hands of

the hard-working military or covenanted branch. We much fear, also, that any sum allowed as staff-salary to surgeons for the highly responsible medical charge of regiments will not be commensurate with their position. The pay for Indian officials must not be calculated on a scale that would suffice for Europe: but rather with reference to the state of the local labour market. Living in India is becoming expensive: so that not only merchants and bankers, but Government, find themselves obliged to raise the rate of pay for all *employés* who are not in their regular covenanted service.

A nominally high pay for the Medical Service may not be adequate for the necessities of a position which must entail considerable expenses of living, of moving from place to place, and probably of taking leave of absence for ill-health; of sending home families, of making suitable provision for them, etc. The reduction of the number of Deputy Inspectors-General, consequent on the transference of all European military charges to the royal surgeons, still further reduces the number of prizes attainable by the Indian medical officer. Consequently, as far as we can judge, the prospects for any one entering the service, are anything but brilliant. However, India is the land of wealth as well as of adventure, and the Indian surgeon may perhaps profit, if not by the great influx of capital, by that of the many European settlers who are making their way to those sunny regions.

MANCHESTER AND SALFORD SANITARY ASSOCIATION.

THE Committee of this Association have just published their Annual Report for the year 1864. It contains much valuable information on subjects connected with the public health. At the end of the report are four quarterly reports on the health of Manchester, drawn up for the Association by Dr. Morgan, the Honorary Secretary. In referring to the cotton famine, the Committee remark—

“In their two preceding annual reports, the Committee endeavoured to show that, although the important trade on which the prosperity of this great centre of the manufacturing districts so largely depends, was for the time paralysed, nevertheless, such had been the liberality and judgment displayed in alleviating the necessities of the operatives, that neither the reports of the Registrar-General, nor the still earlier distress-testing returns of this Association, bore evidence of any increase either in the rate of mortality or in that of disease. The year 1864 tells the same tale as the two which went before. Its statistics demonstrate that, in so far as registers of deaths and diseases tables may be looked upon as an evidence of the public health, the cotton famine failed to bring in its train any of those evils which the most sanguine might well have feared. In the country generally, the death-rate was unusually high. In Manchester, it was below the average.”

The report then proceeds to speak of the number of new cases of disease and injuries occasioned by accidents which occurred in Manchester and Salford during the year 1864.

“The total number observed in public practice amounted to 75,754; of this total, 2645, or 1 in every 28.6, terminated fatally. In the preceding year (1863), the cases reached the still higher aggregate of 82,441; and the deaths 2669, or 1 in 30. If these results be compared with Mr. Royston's mortality-tables, in which the deaths for the year 1864 are shown to have amounted to 12,273, it will be found that 1 death in every 4.6 occurred among a class of patients who are dependent on charity for medical treatment; while, in the year 1863, the proportion was somewhat lower, or 1 in every 4.8. From what has been here stated, as the result of a two years' experience, it would appear that, on taking the poorer class in the mass, each individual is sufficiently indisposed to require medical treatment about thirty times in the course of his life ere he is prostrated by his last sickness; and further, if it be allowable to assume that, in the case of other members of the community, the attacks of sickness bore the same ratio to death as that here assigned to public practice, it would then be found that the total number of new cases of disease which occurred in Manchester and Salford during the year 1863 and 1864 amounted respectively to 391,740 and 351,307; in other words, in the former year, about 13 persons in every 14 required medical aid, in the latter about 5 in 6.”

Scarlet fever last year proved the most fatal of the zymotic diseases; 1124 poor patients having suffered from its attacks, of whom 1 in 10.4 died. The report estimates that the total number of seizures from this disorder in Manchester and Salford, among all classes, in the years 1863 and 1864, fell little short of about 20,000.

Besides collecting and publishing much useful information on subjects connected with the public health, a series of lectures is annually delivered on behalf of the Sanitary Association in different parts of the town. In the course of last year, upwards of thirty lectures were given. In the list of lecturers, we find the names of men well known in the scientific world.

In Dr. Morgan's quarterly and very valuable reports, will be found much interesting information respecting the extent and intensity to which the zymotic diseases prevail in the different districts of Manchester. In one of these reports, he remarks, in speaking of scarlet fever,

“That although it be true that no absolute rate of mortality can be laid down in respect to the zymotic diseases, they still, as a rule, assume a more malignant form in proportion to the extent to which they prevail. In our large cities, at any rate, it rarely happens that affections of this order are altogether absent; sporadic examples of each variety are well nigh always at hand, lurking in those districts which supply a congenial soil for the storing up and dissemination of their specific virus. It is, however, important to bear in mind that among these scattered cases, the disease is far less often followed by fatal results than on those occasions on which it takes on an epidemic form.”

THE MEDICAL PROVIDENT SOCIETY.

WE have much satisfaction in being able to inform our associates that the Medical Provident Society has been, in accordance with the wish of the Directors, duly registered by Mr. Tidd Pratt under the Friendly Societies' Act; and that the Secretary is ready to receive applications for admission from registered practitioners intending to become contributing members.

No material alteration has been made in the Rules of the Society since an outline of them was published in the JOURNAL of February 4th. The tables of annual contributions and benefits, which at that time had not been completed, have since received the sanction of Mr. Finlaison, and will be found in our advertisement columns of this week.

It will be seen, by reference to the table, that practitioners under forty-five years of age may either provide, by a payment ranging from £2:15:6 to £4:5:0 *per annum*, for a weekly payment during temporary disability from sickness or casualty up to the age of sixty-five; or may, by an increased premium the amount of which varies from £3:11:0 to £6:17:0, secure to themselves a similar privilege during the whole of life. Besides these classes, under which it is intended that members shall be ordinarily admitted, it has been provided, in order that every reasonable opportunity may be afforded to practitioners for availing themselves of the benefits of this Society, that, up to the 1st of July, 1867, members between forty-five and sixty years old may be admitted, on payment of the premiums mentioned in the table under Class III; the members admitted in this class being entitled to receive the benefits of the Society during the whole of life, provided that they pay their contributions yearly.

The organisation of the Society having been thus completed, it now only remains for the profession to shew their appreciation of it by becoming contributing members. When it is considered how many days in each year are, on an average, lost to a practitioner through sickness or accident, and how severely this disability often interferes with his power of providing the daily necessities of life for his family; and when it is remembered that the liability to this average annual disability is known to increase rapidly as age advances, it can scarcely be supposed but that many will gladly avail themselves of the opportunity now held out to them of making provision against emergencies by the annual payment of a sum which, all circumstances being considered, is moderate.

In conclusion, we would refer our readers to the letter of the Secretary at p. 443 and to the advertisement; and would urge them to take the earliest opportunity of sending in their name as candidates for admission into this useful Society.

It is interesting to note that the French Imperial Court has recently decided that a medical man cannot legally confide any of his patients to the care of a pupil or an assistant who has no diploma. Any medical man who in future may place his patients in the hands of an assistant who is not legally qualified to practise will become subject to legal penalties.

M. Chenu tells us, in his work on the Crimean campaign, that, during the war, 8,000 French soldiers were slain on the field of battle; 32,000 were wounded, and that of these 9000 died subsequently—making 17,000 killed. But from internal diseases there died no fewer than 60,000.

The papers report the death of Antoine Sue, formerly Surgeon of the Imperial Guard, at the age of 73. He was Physician-in-Chief of the Marseilles Hôtel-Dieu. He was also cousin of the celebrated Eugène Sue, to whom he had taught the elements of his art before he had entered on his famous literary career. The reader may remember that Eugène Sue, in his romances, always showed great respect to physisc and physicians.

The following are the published operations of 143 midwives of Berlin during 1864. The midwives are altogether 155 in number. They attended 17,067 births; of which 8684 were boys, 8211 girls, and 172 whose sex is not stated. Of the mothers, 6 died during delivery, and 42 afterwards, before recovery from confinement. There were 340 children born dead, 186 died during delivery, and 253 in the first nine days after delivery. Of the presentations recorded, 16,205 were head-presentations, 43 face, 159 breech, 56 foot, and cross 95.

There are at the present time in Copenhagen two authorised markets for the sale of horse-flesh, which is sold at twopence-halfpenny a pound. The animal is inspected by a veterinary surgeon before it is allowed to appear in the market as meat for sale. The animal is cut up into four quarters, and the veterinary surgeon burns his official *imprimatur* on each hoof; the hoof is not allowed, under any pretext, to be separated from the quarter; and thus the buyers of horse-flesh have the satisfaction of knowing that they purchase healthy meat.

In the *Berlin. Klin. Woch.*, Dr. Böhm details a case of cysticercus cellulose removed from beneath the conjunctiva. The tumour, of about the size of a bean, was situated at the inner angle of the conjunctiva. It had been growing for some months, and without pain; and had been several times punctured, but always filled again. The patient sought relief chiefly because he could not close his eyelids. In the tumour, when removed, was found a cysticercus. The patient had never suffered from any signs of tapeworm; nor did a dose of kousso expel any pieces of worm from the bowels.

Scientific Notes.

PRODUCTION OF AMMONIA FROM AIR AND WATER, UNDER THE SOLE INFLUENCE OF THE POROSITY OF ARABLE SOIL.

By passing 200 litres of air (at the rate of 10 litres per hour) freed from its natural ammonia, over 250 grammes of ordinary vegetable earth, previously washed, or calcined and washed, or estimated relatively as to its total of nitrogen, then restored to its usual state of humidity, and raised progressively from the temperature of 10° to about 52° cent., M. Decharme found that part of the nitrogen of this air had been transformed into ammonia, into carbonate and nitrate of ammonia. The total amount of ammonia thus produced by the catalytic force of the earth experimented upon was at an average of 0.139 grammes, a small absolute quantity no doubt, but in reality considerable if we compare the atmospheric ammonia to that of rain water. This result shows how all natural causes (winds, rains, changes of temperature and of pressure, etc.), or artificial causes (fallowing, drainage, etc.) which determine the introduction and movement of air in the soil, favour the production of ammonia, and contribute to the development of vegetation, a view perfectly in accordance with the facts observed in practical agriculture. (*Les Mondes*, and *Chem. News*.)

SPOTS OF BLOOD: THEIR AGE.

The red colour of blood-spots begins to change from the second day, the spot becomes visibly brown by the third day, and after a few months it is black, with a slight yellowish tinge. To these well known characteristics M. Pfaff adds others, drawn from the action exercised on these spots by a solution of arsenious acid (containing one grain to two grains of water.) The limit set by him is the time taken by one spot to become pale in this solvent, or until its edges are barely distinguishable from the surrounding substance. When new they dissolve in a few minutes; when from 1 to 2 days old, they require a quarter of an hour to dissolve; from 3 to 8 days old, they require a quarter to half an hour; from 2 to 4 weeks, one or two hours; when one year old and upwards, they demand from four to eight hours.

TEST FOR RUM.

Mix a little of the rum to be tested with about a third of its bulk of sulphuric acid, and allow the mixture to stand. If the rum is genuine its peculiar odour remains after the liquid has cooled, and even after twenty-four hours' contact may still be distinguished. If, on the contrary, the rum is not genuine, contact with sulphuric acid promptly and entirely deprives it of all its aroma. The author affirms that he had never found this very simple process fail, and that all spurious rums may thus easily be distinguished from the genuine. (*Report de Pharmacie & Chem. News*.)

A PHYSICAL ANALYSIS OF THE HUMAN BREATH.

In the August number of the *Philosophical Magazine* is a paper on "A Physical Analysis of the Human Breath," by Mr. W. F. Barrett, Assistant in the Physical Laboratory of the Royal Institution. The experiments were made by the desire, and under the direction, of Professor Tyndall. The mode of analysis is founded upon the calorific absorption exerted by the carbonic acid contained in breath, the apparatus used by Mr. Barrett being mainly the same as that employed by Professor Tyndall in his researches on the absorption of heat by gaseous matter.

DETECTION OF THE ADULTERATION OF ARROWROOT WITH POTATO OR CORN STARCH.

According to J. F. Albers (*Arch. de Pharm.*), this is effected with certainty by means of their behaviour towards hydrochloric acid. When one part arrowroot is shaken with three parts of a mixture of two parts hydrochloric acid of 1.12 specific gravity and one part of distilled water, at ordinary temperatures, for about three minutes, no reaction is observable. But should corn starch be subjected to this treatment, it becomes changed into a gelatinous, translucent, and finally into a semi-fluid mass. Potato starch behaves in the same way, with the production of an easily recognised and characteristic smell. If a mixture of arrowroot with one or more of these substances is to be dealt with, the arrowroot is to be separated by treating the whole for two to three hours with the hydrochloric acid, by which the arrowroot becomes soluble, and may be filtered from the remaining softish mass, which when washed, dried in the air, and weighed, shows by the loss in weight the amount of arrowroot present. (*Chemical News*.)

MINERAL WATERS.

M. Scoutetten, in a memoir, entitled *Researches on Mineral Waters*, attributes their active properties to electricity. By coming into contact with electromagnetic currents in the bosom of the earth, the waters undergo a sort of allotropic modification, which unfortunately does not last when the water comes to the surface, but is gone in three days at most. And now the mystery of mineral waters is unveiled, the author says the medical applications may for the future be made with exactness.

ACTION OF ALCOHOL.

M. Perrin has experimented on the influence of alcoholic drinks taken in moderate quantities on nutrition. He found that less carbonic acid was exhaled from the lungs when wine was taken. His estimations of urea showed nothing particular. He believes with Dr. Smith and others that alcohol is not assimilated, but it affects nutrition by lessening the expenditure of material. (*Chemical News*.)

THE SUN'S OCEAN OF LIGHT.

When the sun is viewed through powerful telescopes, its surface is seen to have a peculiar mottled or curdy appearance. Arago proposed that this envelope should be called the Photosphere. By the elder Herschel, the surface of this photosphere was compared to mother-of-pearl. Other astronomers have said that it resembles the ocean on a tranquil summer day, when its surface is slightly crisped by a gentle breeze, and an undulating play of light is reflected from these little billows. Within the last few years Mr. Nasmyth has discovered a more remarkable condition than any that had previously been suspected. Examining the solar surface with a fine telescope of great penetrating power, this astronomer has discovered objects which are peculiarly lens-shaped. He himself describes them as more like "willow leaves" than anything else. These leaved forms are different in size; not arranged in any order; lie crossing each other; and have an irregular motion. They cannot be less than a thousand miles in length, and from two to three hundred miles in breadth. The most probable conjecture which has been offered respecting those leaf or lens-like objects, is that the photosphere is an immense ocean of gaseous matter in a state of intense incandescence, and that they are perspective projections of the sheets of flame. Whatever they may be, it is evident they are the immediate sources of solar heat and light. (*Popular Science Review*.)

COMPOSITION OF THE ATMOSPHERE.

In a paper read on November 25th before the Manchester Literary and Philosophical Society, Dr. R. Angus Smith said that he believed that his inquiry proved that the oxygen test was a very valuable one, as indicating the condition of the atmosphere. The oxygen was diminished in many cases, and, indeed, in all cases where the air was known to be inferior. The objection to such air might perhaps be found not so much in the absence of oxygen as in the gases which take its place. That place was not wholly supplied by carbonic acid. He believed it needful to examine the composition to the second decimal place in the case of oxygen, and to the third or even fourth in the case of carbonic acid. Hitherto we had had the composition of the air given in numbers varying a tenth per cent.—specimens have generally been taken from rooms or streets or open places indiscriminately. It was the author's wish to show that variations depended on the conditions of soil, situation, wind, etc., and that the oxygen and carbonic acid together might with very minute analysis guide us in sanitary inquiries. (*Chemical News*.)

MANAGEMENT OF LIGHT IN MICROSCOPIC INVESTIGATION.

Mr. J. B. Dancer lately read before the Manchester Literary and Philosophical Society a paper on a contrivance for regulating the amount of light transmitted from the source of illumination to the mirror of the microscope. When viewing certain objects by transmitted light, and particularly with oblique illumination, a very slight alteration in the quantity and direction of the light produced a marked difference in the appearance of the object, especially in Diatomaceae, where a proper management of the light showed lines or markings invisible under ordinary direct illumination. The apparatus exhibited was easily made at a trifling cost; it consisted of a circular disc of blackened tin or cardboard ten or twelve inches in diameter, with a number of perforations of various shapes and sizes—circular, cross-shaped, wedge-shaped, etc.—the centres of which were about three inches and a half from the centre on which the disc, placed perpendicularly, rotates. The form of perforations found generally most useful were parallel slits—slits at right angles to each other—wedge-shaped and circular openings. The object under view must be well illuminated in the direction required, and then the disc, supported by a pillar, was placed between the source of light and the concave mirror, when a few trials would determine the best form of aperture. The markings of *Pleurosigma fasciola angulatum*, etc., might be seen by its aid under powers which would not show them with any arrangement of achromatic condensers, and it also had the good property of shading all but the amount of light required from the lower portion of the microscopic stage and stand. The disc might be attached to the lamp, but it appeared to work better on a stand, and was susceptible of various modifications.

APPARATUS FOR SIMPLIFYING SPECTRUM ANALYSIS.

With this apparatus M. l'Abbé Laborde is enabled to observe the spectra of metals with a small induction coil and a pocket spectroscope, and to compare the spectra of two metals at one time. The description of the apparatus is almost unintelligible in the absence of illustrative cuts, but one remark which the author makes must be quoted. The colour of the bands is a very uncertain means of recognising a metal, and it is far more certain to determine the position of those first seen. He notes in every metal bands of different visibilities, just as in a constellation stars of different sizes are seen. (*Chem. News*.)

NEW SOURCE OF SUGAR.

Dr. De Vry describes the mode of preparation of sugar from the Aren palm, as carried on by the Javanese, as follows. As soon as the palm commences blooming a portion of the stem carrying the blossom is cut away; there exudes from the wound so made a juice containing sugar, which juice is collected in tubes made from bamboo cane previously exposed to smoke, with the view of preventing the otherwise too rapidly proceeding fermentation of the juice under the joint influence of a warm climate, and the presence in the juice of a nitrogenous substance. The juice so obtained is immediately poured into shallow iron pans, heated by fire and inspissated by evaporation, until a drop of the liquid, exposed to cold by allowing it to fall on a cool surface, becomes solidified; if the desired degree of inspissation has been obtained, as evidenced by this experiment, the whole contents of the pan is cast into the shape of big cylindrical lozenges. Many thousands of pounds of sugar are annually obtained in this very primitive manner. I collected in a clean glass bottle a portion of the juice, and found that the unaltered juice does not contain any glucose at all, but it contains a nitrogenous principle which, aided by the warm climate, soon causes the conversion of a portion of the cane-sugar of the juice into glucose. In order to prove, without the aid of any very artificial means, that the juice of the Aren palm contains pure cane-sugar, I collected a portion of juice exuding from the tree, allowing it directly to flow into alcohol; by these means the nitrogenous principle alluded to is at once eliminated by coagulation. I thus obtained a mixture of equal parts of juice and alcohol; after filtration, this mixture was evaporated on a water-bath to the consistency of a syrup. This syrup I took along with me on my journey from Java home, and during the journey the concentrated syrup became solidified, exhibiting rare and beautifully well-defined crystals of cane-sugar, which, by every *connoisseur*, were immediately recognised. Whereas sugar-cane and beet-root require such soils as are also adapted for cerealia, the Aren palm flourishes in soils utterly unfit for that purpose. The Aren palm relishes the deep mountain ravines of Java, running, in some parts of the island, from the sea-shore to the interior, the said palm being found in groups together; and it is quite possible to lay out fine plantations of this beautiful tree. There is one drawback, though not a very serious one, viz., not before the trees have obtained an age of from ten to twelve years are they fit to yield sugar. When, however, it yields sugar, the tapping can be continued for many years, and the sugar manufacture will become a continuous—not as now, an interrupted—industry. (*Chem. News*, February 10th, 1865.)

CONVERSION OF STARCH INTO GLUCOSE BY POTATO PEELINGS.

Starch paste diluted with water, and digested for ten or twelve hours with raw potato peelings at 45° or 50° C. is, accordingly to Leuch, entirely transformed into glucose. (*Chemical News*.)

OZONE AND ANTOZONE.

We understand that Schönbein has at last been successful in his long endeavours to isolate the bodies of which he has contended that ordinary oxygen is composed. Antozone, it is said, has a lower specific gravity than hydrogen. It liquefies at a pressure of 150 atmospheres. Ozone is a denser gas. The two gases combine with a loud explosion when exposed to the actinic rays of the spectrum. Another curious fact mentioned is that a spark of positive electricity does not effect their combination, which is only determined by a negative spark. (*Chem. News*.)

Special Correspondence.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

A CONSIDERABLE reduction in the death-rate, and in the admissions to hospital during the past few weeks, indicate a decided subsidence of typhus. This may be the usual decrease which has marked the progress of former visitations, in the spring and summer, to be followed by an increase in the succeeding autumn; but, as the present epidemic has already existed more than two years—the period which records of previous typhus epidemics assign as their average duration—it may be reasonably supposed that it is about to take its departure altogether.

If this great epidemic should pass away without leaving behind lessons calculated to advance our knowledge of the history and habitudes of zymotic disease, or to add to our therapeutic resources, the deficiency certainly cannot be attributed to lack of discussion or inquiry. In addition to the prolonged debates at the Medical Institution, occupying four meetings of the present session, we have the elaborate and exhaustive report of Dr. Buchanan on behalf of the Privy Council, and that of Dr. French, the Medical Officer of Health for the borough.

The recurrence of an epidemic of typhus in Liverpool, after the lavish expenditure and energetic and comprehensive sanitary operations which have for many years been devoted to the removal or mitigation of the recognised causes of zymotic disease, is a curious and interesting commentary upon the practical results of applied sanitary science.

Until the actual appearance of the present visitation, a long continued immunity from typhus, a progressive decrease in the deaths from fever, and a confidence in the influence of past sanitary measures, had caused considerable hopes that Liverpool would never again see the disease as a serious epidemic.

Dr. Buchanan tells us that, in reference to drainage, middens, and water-supply, there appears to be no ground for assigning to influences of this kind any important share in the production of Liverpool typhus. For, as regards the ordinary prevalence of the disease, other Lancashire towns far worse drained than Liverpool, with middens on the same system and with a worse kind of water-supply, have habitually escaped typhus, while Liverpool has suffered from it; and, as concerns the present epidemic, it is certain that this town has never before been in such a good condition in respect of influences of this kind. He, in the course of his inquiry, further says that there did appear *primâ facie* reason for thinking that certain streets, where the most offensive kind of midden still exists, and certain other streets situate near to the wharf where the contents of the town middens are deposited, had especially suffered from typhus; but, upon accurate examination, the direct connexion between these conditions and the fever was disproved. The conclusions generally to which

very careful and thoroughly exhaustive inquiries into all possible and impossible influences, whether social, sanitary, physical, or moral, which characterise this report, are for the most part negative as regards the causation of typhus. In reference to domestic cleanliness, Dr. Buchanan thinks that the neglect of this virtue is more universal among the poor of Liverpool than among the same class in London, and that, generally speaking, there appeared much connexion between fever and filth; and yet, upon comparison, street by street, between the existing amount of fever and the number of dirty houses, fever and filth were not found to fluctuate exactly together.

As to destitution, he remarks that the evidence connecting the present epidemic with the existence of exceptional destitution does not lead to an absolute conclusion. He thinks that a want of employment and greater destitution may have played some part, though a subordinate one, in determining the first increase of fever at the commencement of 1861; but, as affecting the subsequent progress of the epidemic, increase of fever cannot be proved to have resulted materially from increasing destitution.

The growth of overcrowding, as determined by the annual increase in the practice of sub-letting of the poor tenements, although, in a broad sense, connected with the epidemic of typhus, nevertheless is not, in point of time or extent, found to have been so parallel with the growth of fever as altogether to account for the recent epidemic.

To intemperance he assigns an important influence in keeping up fever directly, by inducing in individuals a constitutional condition incapable of withstanding an attack of typhus, and indirectly by greatly adding to the prevailing destitution. On this point, however, his conclusions are based chiefly upon the statements of the town-missionaries, who assert that they see no destitution except what is the result of drink; and agree that of the cases of fever which come under their cognisance, nearly two-thirds occur in the families of drunkards, an assertion which may be pretty near the truth, but which must not be too readily taken for granted.

He sums up his conclusions by stating, that the reason why typhus is always present in Liverpool may be thus defined. Destitution, dirt, and intemperance, with overcrowding and bad ventilation of streets and houses, are the conditions that keep up the disease steadily from year to year. The reasons why typhus has become epidemic are not so clear. The only positive conditions that have been ascertained, appear to be these: slight but steady increase in overcrowding, some increase of immigration and of distress at the end of 1861, some increase of vagrancy, and with these some influence in each autumnal season. But these causes (he adds) are not sufficient to account for the epidemic. Typhus, like other diseases of its class, has times of subsidence and times of prevalence that medical science cannot yet explain. A partial explanation exists in the different numbers of persons living at different periods who are susceptible to its influence. A person who

has once had typhus is very unlikely to have it again. Immediately after the epidemic of 1847, therefore, when, with hardly an exception, the whole typhus-bearing class of the population had been affected, there were few persons susceptible of the disease. Sixteen years afterwards, a new generation of susceptible persons has arisen, and immigration has brought a multitude of persons from districts where typhus is unknown. Here is a new community for a new epidemic. It has been shown that a vast proportion of the fever has occurred in persons under 20 years of age; and most of whom, therefore, have been born since the last epidemic in Liverpool.

The negative conclusions at which the report arrives concerning the causes of the present epidemic may appear, at first sight, unsatisfactory; but it is not without its value, if it show that efforts for preventing epidemics of typhus must be applied, not chiefly at the time of the epidemic itself, but to the improvement of certain habitual conditions that can be recognised as fostering the disease in ordinary times. Some of these conditions are within the range of public sanitary measures; others are connected with social circumstances over which no direct public control can be exercised.

Further points of interest comprised in this report, together with the consideration of the Annual Report of the Health of Liverpool by Dr. Trench, I must defer to my next communication, when I also propose to give some account of the hospital accommodation in Liverpool for contagious diseases, with a description of the new fever hospital which has lately been erected.

Association Intelligence.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting of this Branch will be held at the Rose Hotel, Canterbury, on Thursday, May 11th.

Notices of papers or cases to be communicated, should be sent immediately to the Honorary Secretary.

ROBERT L. BOWLES, L.R.C.P.,
Honorary Secretary.

Folkstone, April 24th, 1865.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE fifth ordinary meeting of the session was held in Victoria Rooms, Clifton, on Thursday evening, April 13th; R. W. FALCONER, M.D., President, in the Chair. Upwards of forty members and visitors were present.

The minutes of the last ordinary meeting were read and confirmed.

New Members. A. Grace, Esq. (Bristol), and J. C. Leach, Esq. (Bristol), were unanimously elected members of the Association and of this Branch.

Papers. The following papers were read.

1. Notes on a Case of Suicidal Mania. By J. G. Davey, M.D.

2. Additional Note on Intestinal Fever in the Pig; and Epidemic Dysentery in the Pig. By W. Budd, M.D.

In consequence of the lengthened discussions which followed the reading of these papers, it was necessary to postpone several other communications till the next ordinary meeting of the Branch.

Correspondence.

THE COLLEGE OF PHYSICIANS AND THE ARMY AND NAVY MEDICAL OFFICERS.

LETTER FROM A. P. STEWART, M.D.

SIR,—I will not attempt to disguise my regret at the result of the inquiry instituted by the College of Physicians into the grievances of the army and navy medical officers. The College, by a considerable majority, has declined to interfere in their behalf. Yet let no one imagine that this resolution implies a denial either of the existence of their wrongs, or of the substantial accuracy of the Report of the Committee appointed to inquire into them. On the contrary, while the advocates of the *laissez faire* system of policy have objected to—but not disproved—some unimportant details referred to in the Report, the mass of conclusive evidence adduced by the Committee in proof of the anomalous position of both army and navy medical officers, and of the galling and vexatious treatment to which they are continually subjected, was left absolutely untouched, though one member after another of the Committee challenged any one to contradict their statement. And the President, at the close of the discussion, emphatically stated his belief that the grievances of our brethren in the united service are generally admitted, and that he at least had not heard them denied by any one. He further stated his conviction, that there was no want of sympathy with them among the Fellows of the College, who would be happy to see their wrongs redressed; but feared that an unsuccessful interference in their behalf would do harm both to the College and to them.

I have not a word to say against those admirable virtues, modesty and prudence. Nor can I deny my sympathy to those good and unobtrusive people who have greatness thrust upon them whether they will or no. Has not our College of Physicians as good a right as a well known and much respected head master to say, "*Nolo episcopari*," when its admirers, in their mistaken zeal, would thrust upon it a leadership utterly alien to its retiring disposition? Nor will any one expect that I, a canny Scot, should denounce in other nations that caution which is held to be the characteristic attribute of my own people. Least of all, need I be ashamed of it when it rules paramount within the precincts of Pall Mall East, winks hard at acknowledged wrongs, unless intervention is likely to be attended with immediate success, and, courtier-like, bows, cap in hand, before those incarnations of despotic power, the high military and naval authorities. May I not congratulate my English brethren on having so thoroughly made their own the peculiar virtues of the "pawky" north, and on having driven their own uncouth, barbaric, Saxon chivalry to take refuge among the inhospitable Scots, who have so far forgotten themselves and belied their national reputation, as to lead the van in this battle of right against might, regardless alike of the smiles and of the frowns of office. Unluckily for the credit of the English character, in this new phase of its progressive civilisation, one wayward body—the British Medical Association—has sadly compromised itself by too eagerly following the example of the Edinburgh College of Physicians.

But, in imitation of the London College, who appointed a Committee of Inquiry and then gave it a proper snubbing, it may yet atone for past faults, and help to correct the mischief it has wrought, and the annoyance it has occasioned to the constituted authorities, by now drawing in its horns, and leading for the future a quiet and inoffensive life within its shell, even at the risk of dying of inanition.

As a member of the College Committee, I am still perverse enough to think, in common with my colleagues, that we did neither more nor less than our duty both to our constituents and to our clients. I hope the College has some misgivings as to the manner in which they have treated their Committee.

I am, etc., A. P. STEWART.

Grosvenor Street, April 26th, 1865.

POOR-LAW MEDICAL RELIEF.

LETTER FROM R. GRIFFIN, Esq.

SIR,—At a meeting of a majority of the Poor-law medical officers of the Weymouth Union, held at my house this day, the following letter, it was agreed, should be sent to the guardians of this Union; for which you will oblige me by finding space, as it may act as a guide for the great body of Poor-law medical officers.

I am, etc., RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, 24th April, 1865.

To the Board of Guardians of the Weymouth Union.

GENTLEMEN,—In consequence of the Poor-law Board having issued a circular letter to you and all other boards of guardians throughout England and Wales, relative to the supply of cod-liver oil, quinine, and other expensive medicines, for the poor, we have felt it our duty to you, as your medical officers, to hold a meeting on the subject, in order that we may, if possible, assist you in arriving at a right decision on the questions involved, as they are purely medical, and are with difficulty understood excepting by medical men.

We think it right to premise our remarks by stating that the recommendation of the Select Committee on Poor Relief was made for the benefit of the poor, as it was felt that, owing to the expensive nature of many drugs, the Poor-law medical officers could not afford to purchase them out of the very low salaries now paid to them; and, as a consequence, the poor have been but inadequately supplied with them. If, therefore, the guardians should carry out the recommendation of the Select Committee, the present medical officers must not be expected to contribute from their salaries towards the extra expense; but they will most readily assist you towards obtaining them in the most economical manner.

With regard to cod-liver oil, we have no suggestion to offer on the recommendation of the Poor-law Board, further than to inform you that it may be purchased at prices varying from 8s. to 30s. per gallon, according to quality; some of the cheaper kinds being very nauseous to the taste. At about 20s. per gallon, a very good quality ought to be obtained. We would advise your purchasing it done up in four-ounce and six-ounce bottles. In that state, it may be given out to the sick poor either at the work-house, as named by the Poor-law Board, or direct from a druggist, if purchased in Weymouth; or a certain number of bottles may be given to medical officers residing in the country, for their delivery to the poor.

With regard to quinine and other expensive medicines, we feel a difficulty in advising you as to the best course to be pursued, as several drugs frequently enter into the composition of one bottle of medicine,

some very expensive, and others of but slight cost. For instance, quinine is rarely given alone, although it may form the most important ingredient in the mixture. Opium in its various forms, sarsaparilla, iodide of potassium, and the ethers, are all expensive medicines, but are seldom given by themselves. Under these circumstances, you must either place confidence in your medical officers, and allow them to charge extra for those medicines, or else you must allow your officers to order them from the druggists.

We beg further to recommend that leeches should also be found by the guardians, as they are frequently of great importance in the treatment of diseases; but, from their expensive nature, they cannot be found by the medical officers to any very great extent. We have the honour to be, gentlemen,

Your most obedient servants.

Weymouth, April 24th, 1865.

THE MEDICAL PROVIDENT SOCIETY.

LETTER FROM ALEXANDER HENRY, M.D.

SIR,—I have the pleasure of sending you a copy of the Rules and Tables of the Medical Provident Society in connection with the British Medical Association; and shall feel much obliged by your allowing me to inform the profession through your columns that I am ready to receive applications for admission from all duly Registered Medical Practitioners residing in the United Kingdom, and to furnish them with forms of Examination Paper and Certificate.

In accordance with the decision of the Board of Directors, the Society has been enrolled under the Friendly Societies' Act. The Tables have been approved by Mr. Finlaison, the Actuary to the National Debt.

The difficulties under which medical men often labour when prevented by illness or accident from attending to their professional duties, must be well known to you. You will therefore readily perceive, that an institution like the Medical Provident Society, the financial calculations of which have been approved by the highest actuarial authority, must, if well supported and judiciously managed, be at once safe in its operation, and highly beneficial to the contributors.

Allow me also to remind the more wealthy members of the profession that they can give material aid to the Society by donations to its Auxiliary Fund. The sum of £700 has been already subscribed; and the larger this fund becomes, the more stable will be the Society, and less likely to suffer from extraordinary pressure on its Sick Fund. By the Rules of the Society, every registered medical practitioner being a donor of ten guineas or more, is eligible as an honorary member for life.

A copy of the Tables has been sent, to form part of an advertisement in the JOURNAL. I am, etc.,

ALEXANDER HENRY, M.D., Secretary.

15, George Street, Portman Square, W., April 25th, 1865.

BROMIDE OF POTASSIUM IN EPILEPSY.

LETTER FROM S. W. D. WILLIAMS, M.D.

SIR,—As I see by your last week's number that M. Moreau of the Salpêtrière has been trying the bromide of potassium in epilepsy, and seems, from your remarks, to condemn it *in toto*, and as his conclusions are quite contrary to mine, I cannot forbear sending you a few observations on the subject.

I have not seen M. Moreau's article; but from your remarks it appears that, out of the three or four

hundred epileptics in the hospital, "the youngest patients and those most recently affected were chosen for the trial." Now my experience is, that it is exactly "the youngest and those most recently affected" who are likely to receive least benefit from the medicine; and that three grammes in the twenty-four hours for such subjects is much too large a dose, and shows that the *rationale* of the action of the medicine has been misunderstood.

I have now tried it for twenty months; and, although my experiments are not yet quite concluded, I think I can show by a fact or two that the medicine is not altogether *hurtful*.

For ten months I placed under observation nineteen males and eighteen females. During the first five months they took no medicine; and the males had 1012 fits, and the females 1127. Then, for the five following months, I gave each patient from five to ten grains twice daily; the males during this period had 706 fits; the females 970; thus showing a decrease respectively of 306 and 157.

Of the nineteen males, the number of fits decreased in thirteen, increased in five, and remained stationary in one.

Of the females, the number of fits decreased in eleven, and increased in five.

I then omitted the medicine for another five months, and have just completed a fourth period of five months of observation; and I am about publishing a pamphlet on the subject, but have not yet quite completed my calculations.

I hope, however, that I have adduced sufficient to show that the "experts" of the *Salpêtrière* have been somewhat hasty in their conclusions, and enough to allow me to ask the profession to suspend their judgment on this point for a short season.

I am, etc.,

S. W. D. WILLIAMS, M.D., L.R.C.P.L.,
Acting Physician Superintendent, General Lunatic
Asylum, Wolverhampton.

April 24th, 1865.

[M. Moreau's paper will be found in *L'Union Médicale* of April 4th. The remedy was tried by him in fifteen cases. Almost all the patients were between fourteen and nineteen years of age. EDITOR.]

THE RUSSIAN EPIDEMIC. Of the Russian epidemic, the *Wiener Med. Wochens.* says, quoting from a letter from St. Petersburg, dated April 9th: "The inhabitants of this city are systematically cut off from the sick as well as from all news relating to the sickness. Exactly the same way the physicians are treated. Unless a doctor happen to be employed by the police or the military, he is, in the eyes of this Government, a mere ignoramus. He has no admission to the hospitals; nor, in fact, any opportunity for studying the disease. No sooner is a case reported to the authorities, than the poor are carried off to the hospitals, and the wealthy forced to employ a doctor provided by Government. As to ascertaining anything about the plague through the medium of the many foreign physicians sent here, this is a hope which, if it were ever entertained, will be soon enough exploded in your part of the world. These gentlemen have been received with open arms, and in course of time will return home decorated with orders; but that is all. They are shown over the hospitals at a double quick pace; and when a vast number of compliments have been paid them by doctors and attendants, luncheon is announced, and a good deal is consumed at the expense of the hospital. Typhus is said to be spreading in Warsaw."

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. At a general meeting of the Fellows, held on Friday, April 21st, 1865, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the science and practice of medicine, surgery, and midwifery, were duly admitted to practise physic as Licentiates of the College:—

Burrell, Edwin, Westley, Bury St. Edmunds
Earle, Edward Sepimus, 22, Queen Anne Street
Eyeley, Joseph Frederick, Llanymynech
Ferris, John Spencer, 62, Great Russell Street
Foster, Thomas Sheldon, Carnarvon
Gould, Franklin, 25, Charlotte Street, Bedford Square
Groth, Ernest Rudolph Gotthard, M.D. Berlin, 12, Sutherland Terrace, Brixton
Greenwood, Newton, Penryn, Cornwall
Jones, James, 88, St. John Street, Clerkenwell
Lamb, Robert, 162, Caledonian Road
Lawrence, Henry Cripps, 4, Palace Road, Kingston-on-Thames
Thomas, James Byera, Palmaçotta, India

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on April 25th.

Bateman, Francis, Canterbury
Brown, George Arthur, Welchpool, Montgomeryshire
Dowse, Thomas Stretch, Bradford-on-Avon
Evans, George Washington, Strealey, near Reading
Firman, Charles George, Wivenhoe
Foulds, Henry John, Derby
Gill, John, Weston-under-Redcastle, Salop
Gould, Franklin, Charlotte Street, Bedford Square
Hickman, Richard Murhall, Leaton, near Shrewsbury
Jones, Alfred, Chepstow
Jones, George, Loughborough Road, Brixton
Kakeek, Paul Quick, Pontreue, Truro
Ley, Richard, South Molton, Devon
Llewellyn, Rees, Maesgwyn, Breconshire
Melhado, Alfred Courtney Baillie, Bayswater
Oakley, John, Shrewsbury
Reynolds, Howard David, Haverfordwest
Stuckey, John, Langport, Somerset
Swindale, John, Appledore, Devon
Temple, James Algernon, Quebec, Lower Canada
Thomas, Jabez, Swansea
Tindall, Alexander Melvor, Falsegrave, near Scarborough
Whiting, Henry, Southend, Essex
Wright, Edward Seymour, March, Cambridgeshire

APOTHECARIES' HALL. On April 13th, 1865, the following Licentiates were admitted:—

Birtwell, Henry Hargreaves, Blackburn
Edwards, Henry Nelson, 1, Finsbury Square
Megget, Archibald, Scarborough

At the same Court, the following passed the first examination:—

Leverson, Edward James, St. Bartholomew's Hospital
Mule, Philip Henry, St. George's Hospital
Smith, Henry Cecil, Guy's Hospital

As Assistants:—

Barrett, Charles Henry, Bristol
Emmott, Christopher, Gray's Inn Road

Admitted on April 20th—

Covey, George, Basingstoke
Hainsworth, Joseph, Leeds
Jacques, John Thomas, Biratall, Leicestershire
Legg, John Wickham, Alverstoke
Leslie, David, Warwick Street, Pimlico

At the same Court, the following passed the first examination:—

Loughboath, George, Newcastle-upon-Tyne School of Medicine
Truman, Samuel John, Guy's Hospital

APPOINTMENTS.

ROYAL NAVY.

Bishop, John, Esq., Assistant-Surgeon (addit.), to the *Narcissus*.
BRIETZKE, Henry, Esq., Assistant-Surgeon (additional), to the *Rattlesnake*.

KYNSEY, T. F., Esq., Assistant-Surgeon, to the *Gleaner*.
O'CONNOR, Daniel, Esq., Assistant-Surgeon (additional), to the *Pembroke*.
ROBERTSON, George, Esq., Assistant-Surgeon (additional), to the *Victory*.
ROCHE, Thomas, Esq., Assistant-Surgeon (addit.), to the *Victory*.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.= Rifle Volunteers):—

GARNHAM, D. J., Esq., to be Honorary Assistant-Surgeon 1st Lincolnshire R.V.
HEWLETT, T., Esq., to be Assistant-Surgeon 18th Middlesex R.V.
MACKENZIE, D. M.D., to be Honorary Assistant-Surgeon 10th Dumfriesshire R.V.

MARRIAGE.

GOODING—NEWTON. On April 19th, at Alconbury, Huntingdonshire, by the Rev. Jenkin Hughes, John Callender Gooding, M.D., of Cheltenham, to Anne Sweetland, eldest daughter of *Lancelot Newton, Esq., of Alconbury Hill, Hunts.

DEATHS.

ALLEYNE, James H., M.D., at Gloucester Place, Hyde Park, aged 66, on April 21.
BAILLIE. On April 20th, at 87, Prince of Wales's Road, Sarah, wife of B. T. B. Baillie, M.D.
BARNETT. On April 18th, aged 32, the wife of R. Barnett, M.D.
BOCKETT. On March 27th, at Hastings, aged 42, Caroline Emily, widow of William C. Bockett, Esq., Assistant-Surgeon R.N.
BRACE. On April 4th, at Bath, aged 30, Maria, wife of *William H. Brace, Esq.
BRODBURST. On April 11th, at 20, Grosvenor Street, Bernard Maynard, infant child of *B. E. Brodburst, Esq.
CHALK, Frederick M., Esq., Assistant-Surgeon 2nd Battalion 2nd Regiment, at Bermuda, aged 28, on February 9.
CONNELL. On April 14th, at Brompton, aged 69, Maria, widow of James Connell, Esq., Deputy Inspector-General Army Medical Department.
DAVIES, John E., Esq., Surgeon, of Clapham, at Hastings, aged 37, on April 13.
DAY, Edwin E., M.B., at 48, Hertford Street, aged 29, on April 7.
DUNCAN. On April 16th, at Richmond, aged 2 months, the infant daughter of Thomas Duncan, M.D.
GOODEVE. On April 10th, at Drinach, Stoke Bishop, near Bristol, aged 50, Nancy, wife of *Edward Goodeve, M.B., Surgeon-Major Bengal Army.
HARVEY, Henry O., Esq., Assistant-Surgeon 1st Battalion 21st Fusiliers, at Portsea, aged 29, lately.
JORDAN. On March 29th, at Newton Road, Westbourne Grove, Louisa, widow of William P. Jordan, M.D.
KELLY, William, M.D., Surgeon-Major Royal Artillery, at Bath, aged 58, on April 4.
O'GRADY. On April 5th, at Clarendon Street, aged 75, Laura Amelia, wife of C. O'Grady, M.D.
RATTON. Surgeon-Major James, 3rd Light Cavalry, in Bombay, aged 50, on March 5.
RIDING. On April 19th, at 36, Euston Square, aged 7 weeks, William, infant son of W. S. Riding, M.D.
ROBINSON, C. S., M.D., at 23, Harewood Square, on April 1.
SEED. On March 27th, at Rochdale, Elizabeth S. A., wife of Joseph Seed, Esq., Surgeon R.N.
SHARPE, George G., M.D., formerly of Peckham and Stamford, at Epsom, aged 86, on April 18th.
SHARPE. On March 31st, at Epsom, aged 86, Harriott Ann, wife of George G. Sharpe, M.D.
*TEARNE, Edward M., Esq., at Presteign, Radnorshire, aged 41, on April 8.
TOMKIN, W. B., Esq., Surgeon, at Witham, Essex, aged 44, on April 16.
WEBER. On April 1st, at 44, Green Street, Dora Eliza, third daughter of *Frederick Weber, M.B.
WELCHMAN, E., Esq., Surgeon, at Southam, aged 51, on April 17.
WILDBORE. On March 31st, at Old Street, Finsbury, Frances Sophia, wife of Daniel P. Wildbore, Esq., Surgeon.

LONDON HOSPITAL. There is a vacancy for an obstetric physician to the London Hospital, in consequence of the resignation of Dr. Barnes.

UNIVERSITY COLLEGE HOSPITAL. Lord Belper has consented to preside at the annual festival on June 21st.

THE ANNUAL REPORT UPON PUBLIC HEALTH, by Mr. Simon, just published, for all England and Wales, contains an account of the working of our present vaccination laws—"an account," says Mr. Simon, "which offers such a basis as there never yet has been for effective legislation against small-pox." It contains also a full account of the parasitic diseases of animals used for food.

MORTALITY OF TOWN CHILDREN. The Registrar-General for Scotland, in the report for 1861, states that in the town districts of Scotland in that year the children under five years of age died at a ratio more than double that at which they died in the rural districts. Rather more than eight in 100 died in the towns; not quite four in 100 in the rest of the country.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN. The annual dinner of this Society took place on Wednesday last, at the Albion Tavern; Martin Ware, Esq., President, in the Chair. About fifty gentlemen were present; several not being members of the medical profession, but feeling an interest in the Society from their relatives having at some period taken an active part in its management. Of these were the Honourable George Denman (a grandson of Dr. Denman, one of the founders of the Society), the Rev. Mr. Stone (son of the late President), Mr. Russell Gurney (Recorder of London), and Mr. W. H. Baillie. A special general meeting of the Society will be held on May 24th, for the purpose of making the alterations in the laws necessary to the obtaining of a charter.

VACCINATION. In the report of Mr. Simon, medical officer of the Privy Council, made in accordance with the provisions of the Public Health Act, 1858, the following statistics of vaccination are set forth. During 1864, 13,902 applications for vaccine lymph were made to the medical department of the Council Office. Of these 11,182 were from medical practitioners, including 1,383 Poor-law medical officers in England and Wales, 1,657 from Ireland, 516 from Scotland, 229 from the army, 110 from the navy and emigration department, 147 from the colonies, and 61 from diplomatic and other foreign services. There were issued by the department 144,290 charged ivory points, 4,319 charged squares of glass, and 4,075 charged capillary tubes. The quality of the lymph supplied is reported to have been found quite satisfactory everywhere.

A VETERINARY ON "FLUKES": GREEN v. GROVES. An action was tried at Bristol for the breach of a warranty of some sheep. One of the lambs died of inflammation of the lungs. On the liver being cut open, "a fluke popped out", as one witness expressed it; a "fluke" being a parasitic animal, an inch long, and a quarter of an inch broad. Another lamb died soon after, and in the liver three flukes were found. Others were killed, in some of which flukes were found. This, the plaintiff contended, was a breach of the warranty. A veterinary surgeon admitted that the presence of a few flukes in a sheep's liver was in no way whatever hurtful, not even up to ten or twelve; and that damage to the sheep only ensued when the flukes were in very large numbers; and that all animals contained worms or parasitic animals. Mr. Cole, who moved for a new trial, urged strongly on the court that the flukes did no harm to the sheep, but were rather beneficial than otherwise, inasmuch as the sheep became fatter when these little creatures inhabited the liver. Mr. Justice Blackburn: I earnestly hope my butcher does not know that.

COTTAGES OF THE AGRICULTURAL POOR. A report, by Dr. H. J. Hunter, on the state of the dwellings of rural labourers, made to the Privy Council, contains much valuable information. Some of his deductions are as follows. The condition of the agricultural labourer's house accommodation has been for many years past steadily deteriorating. House room is greatly more difficult to find, and, when found, very much less suitable to his needs, than has been the case for centuries. The household circumstances of the agricultural labourer are, therefore, now in the

highest degree deplorable. Whether he shall find house room at all on the land that he tills depends on the will of the owners of the land. Each parish has a pecuniary interest in reducing the number of its resident labourers; for their lives are for the most part a longer or shorter circuit to eventual pauperism—a pauperism which during the whole circuit is so near, that any illness or temporary failure of occupation necessitates immediate recourse to parochial relief. Large proprietors resolve that there shall be no labourers' dwellings on their estates, and thus free themselves from their responsibility for the poor. These reasons find effect in the destruction of cottages. The labourers are driven to more crowded dwellings in the villages, and at a distance from where they work, it may be of three or four miles, adding a walk of six or eight miles per day to their hard labour for daily bread; and many other evils can be traced to this depopulation of their lands by the great owners in order to escape poor-rates. It is now the common conclusion of competent observers, that even the general badness of the dwellings of agricultural labourers is an evil infinitely less urgent than their mere numerical insufficiency.

ODONTOLOGICAL SOCIETY. A meeting was held on April 3rd, 1865, the President, Thomas A. Rogers, Esq., in the chair. After the ordinary business Mr. Merryweather exhibited a case of casts showing the conditions of the same month from the age of 4 years till 21, at intervals of six months. Mr. Vasey exhibited models referred to at last meeting. Mr. Walker related the history of several cases which had occurred in hospital practice of abscesses in the jaws. Mr. Harrington explained the nature of a self-acting drill which he exhibited, adapted to lessen the difficulty of cutting away the carious parts of teeth. He had successfully used the drill since June 1863. Mr. Hulme read a paper on Rhizodontripsy, or the drilling into the pulp cavity. After referring to the history of this operation, the author related the circumstances attending its performance in a patient of his own whose tooth he had a subsequent opportunity of dissecting. The tooth showed a secondary deposit of dentine. From this and other cases the author deduced conclusions favourable to the theory of Dr. Hüllihen; and observed that in any case the subject was worthy of investigation. He recommended that a careful collection of statistics should be made. An interesting and lengthened discussion followed, in which Messrs. Rogers-Harrison, Vasey, Walker, and Coleman took part. The Society then adjourned.

EPIDEMIC YEARS. Another annual report of the Scottish General Register Office has been issued. This report, which is for the year 1861, shows among other things the light which may be cast by the returns upon the question whether epidemic diseases are contagious or not. From the time when the Registrar-General for Scotland opened his books on January 1st, 1855, and began to register the death and the mortal disease of every one whose breath departed in Scotland, the wave of zymotic disease (scarlatina, whooping-cough, small-pox, typhus, and the rest) was gradually rising, and covering the country like a storm; in England it attained its *maximum* in 1858, but, taking nearly a year in travelling, the *maximum* was not attained in Scotland until 1859. In 1861 it had subsided, and the deaths from the zymotic class of disease fell to about a fifth of the total mortality. Now the Scottish returns show that in the non-epidemic year 1861 the mortality from zymotic disease bore substantially the same proportion to the entire mortality in town and in country, in the crowded and in the rural population; and the conclusion drawn is that in ordinary years epidemic

diseases are not, any more than other diseases, propagated by contagion. In 1861 the total deaths in towns in Scotland were to the total deaths in the insular districts nearly as five to three, and the deaths from zymotic diseases also were nearly as five to three. It is argued that these latter are no more propagated by contagion, to any appreciable extent, than bronchitis or consumption or rheumatism. On the other hand, in epidemic years diseases of the zymotic class appear to be largely propagated by contagion. The year 1859 was notably an epidemic year in Scotland; in that year if the deaths from zymotic diseases in the town districts had borne the same proportion to the total deaths as in the insular districts 460 persons in every 100,000 would have been cut off by this class of diseases in the towns; but, in fact, 689 deaths occurred, very much more than the regular proportion due to a town's increased mortality. The same fact was nearly as strongly shown in 1860, also an epidemic year; so that in epidemic years the zymotic class of diseases appears to propagate or spread not only by virtue of their unknown epidemic or endemic constitution, but also to a very large extent by means of contagion, or, in other words, when zymotic diseases assume the true character of epidemics, they become capable of being propagated by contagion. Indeed, it has been often observed that the diseases termed epidemic, of whose propagation by contagion not a trace appears for a considerable period, seem in other years to change their nature, so that they not only spread by reason of their unknown epidemic agency, whatever that may be, but also to a considerable extent by contagion. It will be noticed, however, that the present observation is of town populations in the aggregate, without any separation into classes living under avoidable unhealthy conditions, and classes subject to no known unfavourable influence except density of population.

SEWAGE OF TOWNS. The Sewage Commission has just issued a third report. They make the following statements, as the results of their labours, extending over eight years. "1. The right way to dispose of town sewage is to apply it continuously to land, and it is only by such application that the pollution of rivers can be avoided. 2. The financial results of a continuous application of sewage to land differ under different local circumstances; first, because in some places irrigation can be effected by gravity, while in other places more or less pumping must be employed; secondly, because heavy soils (which in given localities may alone be available for the purpose) are less fit than light soils for continuous irrigation by sewage. 3. Where local circumstances are favourable, and undue expenditure is avoided, towns may derive profit, more or less considerable, from applying their sewage in agriculture. Under opposite circumstances, there may not be a balance of profit; but even in such cases a rate in aid, required to cover any loss, need not be of large amount. Finally, on the basis of the above conclusions, we further beg leave to express to your lordships that, in our judgment, the following two principles are established for legislative application: First, that wherever rivers are polluted by a discharge of town sewage into them, the towns may reasonably be required to desist from causing that public nuisance; second, that where town populations are injured or endangered in health by a retention of cesspool matter among them, the towns may reasonably be required to provide a system of sewers for its removal. And should the law, as it stands, be found insufficient to enable towns to take land for sewage application, it would, in our opinion, be expedient that the legislature should give them powers for that purpose."

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Disease of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY.....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Epidemiological Society, 8 P.M.—Entomological.—Royal Institute (Anniversary).
TUESDAY. Pathological Society of London, 8 P.M.—Anthropological Society of London, 8 P.M.
WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Odling, "On the Chemistry of Tissue-Metamorphosis."—Obstetrical Society of London, 8 P.M. Dr. Barnes, "On Dysmenorrhoea, Menorrhagia, and Sterility; and the Relief of these Affections by Division or Dilatation of the Cervix Uteri"; Mr. H. W. Sharplin, "Case of Ovariectomy."
THURSDAY. Harveian Society of London, 8 P.M. Dr. Sisson, "On the Remedies for Dropsy."—Royal.—Linnæan.—Chemical.
FRIDAY. Royal College of Physicians, 5 P.M. Dr. Odling, "On the Chemistry of Tissue-Metamorphosis."—Western Medical and Surgical Society, 8 P.M. Mr. C. Hunter, "On the Progress of the Hypodermic Treatment"; Nomination of Officers for the next Session.—Royal Institute.

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

THE ENDOSCOPE.—Dr. Fleming presents his compliments to the Editor of the BRITISH MEDICAL JOURNAL, has had his attention directed to a paragraph which appeared in the last number of that JOURNAL, under the heading of "The Endoscope", in which it is stated "that some experiments made by Dr. Fleming, in connexion with that instrument, and detailed by him at a meeting of the Surgical Society of Ireland, on the 17th instant, had already been made familiar to the profession by Dr. Cruise." Such statement is not correct. The only experiment mentioned by Dr. Fleming on the occasion alluded to, was that of his introducing into the bladder of a male subject, foreign substances of different kinds, with the object of testing the accuracy of M. Desormeaux's Endoscope, as to the detection of their presence, their outline, and their colour, even in the dead subject. Dr. Fleming was assisted by Mr. Little, and by many other of the pupils of the Richmond Hospital, in that experiment; and if it have had any merit, it most unquestionably had that of priority of performance of any similar experiment by Dr. Cruise, who was aware that such was the fact, and also of priority of communication to the profession. Dr. Fleming is not aware of any experiments being made familiar to the profession by Dr. Cruise.

Dr. Fleming begs to apologise to the Editor of the BRITISH MEDICAL JOURNAL for thus trespassing upon him; but he ventures to hope that, under the circumstances, he will excuse him, and that he will rectify a statement inaccurately communicated.

6, Merrion Square North, Dublin, April 24th. 1865.

NON-COMBATANT (?) OFFICERS DECORATED.—(F.T.) It is a fact worthy of note that, after the battle of Wagram, Napoleon honoured Larrey, Percy, and Desgenettes, with the very same decorations as those which he bestowed on Marshal Macdonald.

THE VENEREAL DISEASE COMMISSION.—The Commission, now sitting on Venereal Diseases, was appointed by the War Office and Admiralty authorities conjointly. But, as the investigation has been more lengthy than was anticipated by those authorities, the sanction of the Treasury has been obtained for the payment of the expenses of the protracted inquiry.

THE JOURNAL OF MENTAL SCIENCE for April contains articles on Psychology of Idiocy; Remarks on Neuropathy, by Dr. Chapman; Artificial Insanity, by Dr. D. H. Tukey. Townley's Suicide is also referred to; and, we would suggest to our contemporary, in language of a too strongly personal character. Dr. Robertson continues his paper on the Extending of the Public Asylum System; and Dr. Wilks gives Clinical Cases.

SIGNING CERTIFICATES OF LUNACY.—SIR: Lawyers are surprised that we sign certificates of lunacy at all, the risk is so great. But in private practice, we know that the risk must be run. We must risk it as we do that of infection and contagion. Still, in both instances, it is prudent to guard against danger.

I beg to inclose a form which, in a recent case, was signed by the wife, the brothers and the sisters of the lunatic. It was prepared by an able barrister, who advises that as many of the family who are responsible persons should sign it; and that it should be sent within a fortnight to Somerset House, to be stamped. The stamp is sixpence.

If your medical readers were to make a copy of this form for these emergencies, they might, with perfect fairness to their patients, refuse to sign a certificate of lunacy, unless this risk was shared by the family.

I am, etc.,

JOSEPH BULLAR, M.D.

Physician to the Royal South Hants Infirmary.

Southampton, April 1st, 1865.

To Dr.

And Dr.

Gentlemen.—We, the undersigned, having requested you to sign a certificate for the admission into a lunatic asylum of Mr.

whom we believe to be a person of unsound mind, who ought to be confined in an asylum for lunatics, do hereby, in consideration of your so signing the same, and permitting the same to be used at our request, agree and undertake as follows:

First, to guarantee and save harmless you and each of you against all costs, damages, and expenses of you or either of you, and all claims and demands against you or either of you, by reason of or touching your signing the same certificate or permitting the same to be used; and

Secondly, that you and each of you shall be completely indemnified by us against all the consequences of you and each of you so signing the same and permitting the same to be used;

Thirdly, we undertake to defend, at our own cost, any action, suit, or other proceeding against you, or either of you, touching or relating to that certificate or to the use thereof, or to the confinement and treatment of the said lunatic by reason thereof.

As witness our hands, this day of , 1865.

COMMUNICATIONS have been received from:—MR. WILLIAM CORNEY; DR. E. L. ORMEROD; MR. J. RHODES; THE HONORARY SECRETARY OF THE HARVEIAN SOCIETY OF LONDON; DR. JAMES RUSSELL; MR. J. S. GAMGEE; DR. T. RADFORD; THE HONORARY SECRETARY OF THE OBSTETRICAL SOCIETY; DR. S. W. D. WILLIAMS; DR. BOWLES; DR. SANKEY; MR. NEWTON; DR. T. SNOW BECK; DR. G. JOHNSON; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; DR. C. FLEMING; DR. ANDERSON; MR. RICHARD GRIFFIN; MR. STONE; MR. JABEZ HOGG; and MR. J. B. CROGENSEN.

BOOKS RECEIVED.

1. The Surgery of the Rectum; being the Lettsomian Lectures on Surgery, 1865. By Henry Smith. London: 1865.
2. Thomson's Synopsis of the British Pharmacopœia. By E. L. Birkett, M.D. London: 1865.
3. On Letters Patent for Inventions. By F. Edwards. London: 1865.

7. Hull General Infirmary. Account of In-patients. 1864.
8. Vital and Economical Statistics of the Hospitals, Infirmary, etc., of England and Wales, for the Year 1863. By Fleetwood Buckle, M.D. London: 1865.
9. Annual Report of the Bourton-on-the-Water and Cotswold Village Hospital. January 1865.

ESTABLISHED 1848.

Mr. J. Baxter Langley, M.R.C.S.
Eng. (late of King's College, London), PROFESSIONAL
AGENCY, 50, Lincoln's Inn Fields, W.C.

Wales.—In an improving and
much frequented locality on a main line of railway, a *bond fide* Practice for immediate transfer. Income £500. One horse only requisite. No assistant. Midwifery £1 ls. and upwards. House new and well situate, with stable, etc., at a low rent. To an eligible gentleman, speaking Welsh, the whole Practice can be transferred. From an immediate purchaser a very low premium would be accepted. Address "S., 1157," care of Mr. Langley, as above.

Death Vacancy.—In Devon, in
a thriving Market Town, private Practice of deceased, £430 on three years' average. Appointments £15, secured to successor. To secure an immediate successor a small premium would be accepted. Address "S., 1156," Mr. Langley, as above.

In a good Cathedral Town.—For
transfer, a good family Practice, established ten years. Patients wholly of the upper and middle class. No club or parish appointments. No obstetric fees under £1 ls. Good house and garden. Expenses very small. Receipts between £500 and £600. Further investigation permitted, and a satisfactory introduction given Premium £550. Address "S., 1155," care of Mr. Langley, as above.

In one of the best Towns in
LINCOLNSHIRE.—For transfer, a family Practice, the cash receipts in which are about £500. Patients—good farmers, tradespeople, etc. The locality is healthy and picturesque. Three months' introduction. For terms, etc., Address "S., 1153," Mr. Langley, as above.

In a pleasant Suburb in London.
—For transfer, an excellent and improving family Practice. Receipts last year £630. The books have been submitted to Mr. Langley, who can testify to the *bond fides* of the statements of the vendor. Six months' introduction. One year's purchase required. Address "S., 1106," Mr. Langley, as above.

University of Edinburgh.

THE SUMMER SESSION OPENS IN MAY.

<i>Scots Law</i> —Professor MOIR	Monday, 22nd May, 10 A.M.
<i>Botany</i> —Dr. BALFOUR, at the Garden	Tuesday, 2nd May, 8 A.M.
<i>Botanical Demonstrations, in the Garden and Hothouses</i> —Dr. BALFOUR	Monday, Wednesday, } 9 A.M.
<i>Botanical Examinations, in the College</i> —Dr. BALFOUR	Wednesday, 3 P.M.
<i>Anatomical Demonstrations</i> —Mr. TURNER, Mon., Wed., and Fri., under the superintendence of Prof. Goodsir	Wednesday, 3rd May, 2 P.M.
<i>Medical Jurisprudence</i> —Dr. MACLAGAN	Tuesday, 2nd May, 11 A.M.
<i>Clinical Surgery</i> —Mr. SYME	Tuesday, 2nd May, 12 noon.
<i>Clinical Medicine</i> —Dr. MACLAGAN	Tues., 2nd May, 12 to 2 P.M.
<i>Natural History</i> —Dr. ALLMAN	Tuesday, 2nd May, 1 P.M.
<i>Practical Histology and the Use of the Microscope</i> —Dr. BENNETT, Tu. & Fri.	Friday, 5th May, 3 P.M.
<i>Medical Psychology</i> —Dr. LAYCOCK, Mon., Wed., and Thurs.	Thursday, 4th May, 3 P.M.
<i>Practical Instruction in Mental Diseases</i> —Dr. LAYCOCK, Saturday	Saturday, 6th May, 1 P.M.
<i>Sanskrit</i> —Professor AUFRECHT	Tues., 2nd May, 11 & 12 noon.
<i>Theory of Music</i> —Prof. DONALDSON	Tuesday, 2nd May, —
<i>Hindustani, &c.</i> —Professor LISTON	Wednesday, 3rd May, 10 A.M.

For particulars apply to the Librarian.

Royal Infirmary

Dissecting Rooms open daily, under the superintendence of Mr. GOODRICH, assisted by WM. TURNER, M.B. Lond., and Dr. TRAQUAIR.

Chemical Laboratories—The Upper Laboratory, for instruction in Analytical Chemistry, and for Chemical Investigation, under the superintendence of the Professor, aided by Mr. DITTMAR as Chief Assistant, is open from Ten to Four. The Lower Laboratory, for instruction in Practical Chemistry, is conducted by Dr. DALZELL, under the inspection and Supervision of the Professor.

PHILIP KELLAND, Sec. to the Senatus.

1st April, 1865.

Liverpool Royal Infirmary and SCHOOL OF MEDICINE.—The SUMMER SESSION commences on Monday, May 1, 1865.

HOSPITAL PRACTICE—ROYAL INFIRMARY.

Physicians—Dr. Vose, Dr. Turnbull, Dr. Inman.
Surgeons—Mr. Stubbs, Mr. Long, Mr. E. R. Bickersteth.
House-Surgeons—Mr. Nash and Mr. Holyoake.
Dental Surgeon—Mr. Snape. Pathologist—Dr. Rawdon.

The Hospital contains 275 Beds. The number of In-Patients is upwards of 2,300 annually, and 2,592 Surgical Casualties were last year treated as Out-Patients.

Clinical Lectures are regularly delivered by the Physicians and Surgeons.

Six Dressers and Six Clinical Clerks are elected quarterly from the Pupils of the Infirmary.

LECTURES.

Midwifery and Diseases of Women—Dr. Grimsdale.
Diseases of Children—Dr. Gee.
Materia Medica and Therapeutics—J. Birkbeck Nevins, M.D. Lond.
Medical Jurisprudence and Toxicology—E. Whittle, M.D. Lond., M.R.I.A., and J. B. Edwards, Ph.D.
Botany—C. Collingwood, M.A. Oxon., M.B. M.R.C.P.
Ophthalmic Medicine and Surgery—R. Hibbert Taylor, M.D.
Practical Chemistry—J. B. Edwards, Ph.D.
Pathological Anatomy—Dr. Rawdon.
Dental Surgery—Mr. Snape, L.D.S. R.C.S.
Dental Mechanics—
Dental Anatomy and Physiology, Comparative and Human—Mr. Fletcher.
Metallurgy—Dr. Edwards.

F. D. FLETCHER, Secretary, 13, Mornington Terrace, Liverpool.

Guy's Hospital.—The Summer SESSION commences on Monday, May 1st.

MEDICAL OFFICERS.

Physicians—G. H. Barlow, M.D.; G. Owen Rees, M.D., F.R.S.; W. W. Gull, M.D.
Assistant Physicians—S. O. Habershon, M.D.; S. Wilks, M.D.; F. W. Pavy, M.D., F.R.S.
Surgeons—Edward Cock, Esq.; John Hilton, Esq., F.R.S.; John Birkett, Esq.; Alfred Poland, Esq.
Assistant Surgeons—Cooper Forster, Esq.; Thomas Bryant, Esq.; Arthur Durham, Esq.
Obstetric Physician—Henry Oldham, M.D.
Assistant Obstetric Physician—Braxton Hicks, M.D., F.R.S.
Surgeon-Dentist—J. Salter, Esq., F.R.S.
Surgeon of the Eye Infirmary—Alfred Poland, Esq.
Assistant Surgeon of the Eye Infirmary—Charles Bader, Esq.
Aural Surgeon—J. Hinton, Esq.

LECTURES, &c.

Demonstrations on Cutaneous Diseases—S. O. Habershon, M.D.
Medical Jurisprudence—A. S. Taylor, M.D., F.R.S.
Materia Medica—S. O. Habershon, M.D.
Midwifery—Henry Oldham, M.D., and J. Braxton Hicks, M.D., F.R.S.
Ophthalmic Surgery—Alfred Poland, Esq., and C. Bader, Esq.
Pathology—S. Wilks, M.D.
Comparative Anatomy—F. W. Pavy, M.D., F.R.S., and W. Moxon, M.D.
Use of the Microscope—A. Durham, Esq.
Botany—C. Johnson, Esq.
Practical Chemistry—Thomas Stevenson, M.D.
Demonstrations on Manipulative and Operative Surgery—T. Bryant, Esq.
Clinical Medicine—Dr. Habershon, Dr. Wilks, and Dr. Pavy.
Clinical Surgery—Cooper Forster, Esq., T. Bryant, Esq., A. Durham, Esq.
Clinical Obstetrics—Dr. Oldham and Dr. Braxton Hicks.
Vaccination—Dr. Braxton Hicks.

Gentlemen desirous of becoming Students must give satisfactory testimony as to their education and conduct. They are required to pay £40 for the first year, £40 for the second year, and £10 for every succeeding year of attendance, or £100 in one payment entitles a Student to a Perpetual Ticket.

Dressers, Clinical Clerks, Ward Clerks, Obstetric Residents and Dressers in the Eye Wards, are selected from the Students. Three House Surgeons are appointed every six months.

Arrangements will be made to afford every Student such opportunities of acquiring Practical Surgery as are in accordance with the New Regulations of the College of Surgeons.

Six Scholarships, varying in value from £25 to £40 each, are awarded at the close of each Summer Session for general proficiency; also a Governor's Prize of £10.

Two Gold Medals are given by the Treasurer—one for Medicine and one for Surgery.

There is a Voluntary Examination in October, in Elementary Classics and Mathematics. The three first candidates will receive respectively £25, £20, and £15.

Mr. Stocker, Apothecary to Guy's Hospital, will enter Students, and give any further information required.

Guy's Hospital, April 8, 1865.

Notes

ON

THE PATHOLOGY AND TREATMENT OF CHOLERA.

BY

GEORGE JOHNSON, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN TO KING'S COLLEGE HOSPITAL; ETC.

THERE are few diseases, the treatment of which has been more influenced by pathological theories than cholera. The theory which has gained almost universal acceptance is, that the worst symptoms of the disease are due to the drain of fluid from the blood. The practice which has been based upon this theory is to check the purging by opiates and astringents, and to restore to the blood its lost constituents by saline injections into the veins. What if this theory be erroneous, and the practice suggested by it injurious? That the theory and the practice are both wrong, I am persuaded; and I propose now to give the reasons for my belief.

First, then, let us inquire, *What is the relation between the symptoms of choleraic collapse and the loss of fluid by vomiting and purging?* It will, I suppose, be conceded by all who are prepared to argue this question, that if the symptoms of collapse are occasioned by a drain of fluid from the blood, there must, as a rule, be a direct relation between the degree of collapse and the amount of liquid which escapes from the blood. Now, so far is this from being the case, that there are few writers of any note or authority upon the subject of cholera who do not either assert distinctly, or record facts from which the inference plainly follows, that not only is there no direct relation between the loss of liquid by vomiting and purging and the degree of collapse; but that these conditions often bear an inverse ratio to each other. In confirmation of this statement, I purpose now to quote some of the best known authors on the subject of cholera.

Dr. Edmund Parkes says: "My cases bear out the observations of Scott, Jameson, Orton, Kennedy, Copland, and, in fact, almost all the English writers of reputation, that there is absolutely no ratio between these two classes of symptoms" (*i. e.*, between the purging and vomiting and the symptoms of collapse) "or that they appear even to observe an inverse ratio to each other. Thus, at a period of the case when the algide symptoms were most fully developed—viz., in the last five hours—the purging ceased; in the cases where the algide symptoms were prominent throughout, and which cases were consequently the most malignant and the most rapidly fatal, the passage of fluid from the intestines was oftentimes trivial in degree and shortened in the period of its occurrence. In cases in which the vomiting and purging were excessive, the algide symptoms often came on slowly, and were less marked and deadly." (*Researches into the Pathology and Treatment of the Asiatic or Algide Cholera.*)

Dr. Parkes, then, in illustration of these remarks, cites some cases in which the frequency of the vomiting and purging was quite out of proportion to the severity of the other symptoms. He afterwards states that "it may be objected to observations of this kind, that the number of stools is, after all, no certain indication of the amount of fluid passed.

This objection would be of weight in cases where the stools were not very different in number; but in some of these cases cited above, we have two or four stools attended by more rapid death than twenty-five or twenty stools; and yet, in the first case, it would be impossible not to suppose the quantity of the fluid passed to be much below that of the second case." He adds, "it may be confidently asserted that there is no one who has seen much of cholera who does not know that, exclusive of the mildest forms of the disease, a case with little vomiting and purging is more malignant and more rapidly fatal than one in which these are prominent symptoms."

With reference to the varieties in the general symptoms of cholera, Scott makes the following statement: "A frequent variety, the worst of all, is that which is noted for the very slight commotion in the system; in which there is no vomiting, hardly any purging—perhaps only one or two loose stools—no perceptible spasm, no pain of any kind; a mortal coldness with arrest of the circulation comes on from the beginning, and the patient dies without a struggle. This has frequently manifested itself as the prevailing type, and almost all die who are attacked by it." (*Report on the Epidemic Cholera.*)

The testimony of Bell is to the same effect. He says: "It has been found that the more violent the prominent symptoms are, the more likely is a cure to be effected; and that when the disease is attended with rapid collapse, little or no vomiting and purging, and no spasm, the prognosis is very unfavourable." (*Treatise on Cholera, Asphyxia, or Epidemic Cholera.*)

Orton, in several passages of his essay, alludes to the fact that, in the worst forms of the disease, vomiting and purging are slight or quickly cease, or even do not occur at all. (*An Essay on the Epidemic Cholera of India.*)

Twining gives cases which illustrate the same general principle. Thus, he reports (*Clinical Illustrations of the More Important Diseases of Bengal*, p. 10) the case of a gentleman who died nine hours after the commencement of urgent symptoms, in whom there were occasional slight efforts to vomit at intervals of half an hour, and he had only four stools from the commencement to the termination of the attack. And, in another part of his work (p. 37), he says, "We often see patients vomiting violently for hours, and others purged profusely for several days without cholera (*i. e.*, collapse) coming on."

The authors above cited have all observed the disease in India; but the testimony of those who have witnessed it in Europe is in strict accordance with that of the Indian authorities. Thus, Magendie, describing cholera as he saw it in Paris in 1832, makes the following statement: "Some patients have no evacuations, insomuch that one is obliged to excite them; for the evacuations, though associated with the disease, are not one of the most serious symptoms; and those patients who have had copious evacuations have been more easily treated than those who have had none. This is a remark which has been made by many physicians." (*Leçons sur le Cholera Morbus.*)

Mr. French states, amongst other reasons for believing that the intestinal discharges are salutary, that while "cholera, in its most intense form, produces death instantly without discharges, all those who recover from its attack experience the peculiar discharges more or less." And, again, in favour of the same view, he says, is "the ultimate recovery of persons who have continued in a state of collapse for a considerable length of time, often extending to a period of three days, and who, in all instances, sustained enormous discharges." (*The Nature of Cholera Investigated.*)

Dr. Gull, in his *Report on the Morbid Anatomy and Pathology of Cholera*, published by the Royal College of Physicians in 1853, cites the evidence of several practitioners to the effect that, in many cases, "the evacuations appeared to be wholly insufficient to account for the fatal collapse." And one case which came under Dr. Gull's observation, affords a striking illustration of the same principle. "On a *post mortem* examination, the large intestines contained healthy fæces; whilst in the upper two-thirds of the small intestine, the mucous membrane presented the ordinary changes induced by the cholera process, and the rice-water effusion was abundant." Dr. Gull adduces this case to show that "*cholera sicca*, in a strict sense, does not occur; for although the disease may be fatal without any evacuation, the intestines after death, in such cases, have been found to contain the rice-water fluid." It can scarcely be doubted, however, that when, as in this case, the purging has been insufficient to remove the fæculent contents of the large intestine, the loss of fluid must have been out of all proportion less than in most cases in which recovery takes place. And Dr. Gull, in another part of his Report (p. 211), admits that "the intensity of the symptoms is often in no inconsiderable degree greater than can be accounted for by the amount of the effusion."

With respect, then, to the question whether there is any direct relation between the loss of fluid by purging and the symptoms of collapse, we have a large amount of concurrent testimony to the effect that no such relationship exists.

Even admitting that there were a direct and constant relationship between the loss of fluid and the degree of collapse, further evidence would still be required to prove that they stand to each other in the relation of cause and effect. It might be that they are only the effects of one common cause, which while, on the one hand, it gives rise to collapse, on the other excites vomiting and purging. How far this may be the case, we shall have to consider hereafter. In the meantime, it must, I think, be conceded, that the evidence of there being an inverse rather than a direct ratio between the degree of collapse and the loss of liquid by vomiting and purging, is fatal to the hypothesis so generally received and acted upon, that choleraic collapse is caused by the drain of liquid from the blood.

We will next go on to inquire whether the symptoms of collapse are such as an excessive drain of liquid from the blood might be supposed to produce.

[To be continued.]

THE PRITCHARD CASE. The *Glasgow Herald* says: "The prisoner retains the same amount of self-possession that he has exhibited since the night of his apprehension. A day or so after his incarceration he seemed to feel a little annoyed that he could not be favoured with a supply of pomatum for the trimming of his beard and hair. The prison regimen has not at all suited his taste, but he does not seem to have lost flesh, and his pale appearance may be ascribed to the confinement. In fact, so far as we learn, Dr. Pritchard has all along taken matters very coolly. We are told that to a lady whom he met in the street shortly after Mrs. Pritchard died he remarked 'that his beloved wife was gone, that her death had resulted from an attack of typhoid fever, that he had called in three doctors to visit her on the day prior to her death, but that it had been of no use.' 'Too many cooks, he added, spoil the broth.' In point of fact, only one doctor—viz., Dr. Paterson, saw Mrs. Pritchard on the day prior to her death."

Original Communications.

A WORD CONCERNING THE USE OF BROMIDE OF POTASSIUM.

By E. H. SIEVEKING, M.D., Physician in Ordinary to H.R.H. the Prince of Wales.

THE number of morbid conditions of an uniform character, and allowing of a statistical enumeration of the effects produced by any given remedies, is so small, that we must necessarily, in the present state of science, be extremely sceptical as to any statement averring or denying the efficacy of a drug employed in their removal. There is an inherent weakness in all attempts to tabulate the results of treatment in the great majority of diseases that meet us, not because treatment is useless or the medicinal agents valueless, but because the wise physician does not regard the disease as a nosological abstraction but as a deviation from the healthy standard involving a great variety of elements, each of which may in its turn differ in degree, character, relation, in any given number of patients brought together for comparison. How often do we meet with uncomplicated disease of one organ or tissue? Does it, in fact, ever exist? Or does not rather the whole history of medicine, as well as our individual experience, demonstrate the variability of morbid phenomena according to the circumstances of family history, personal habits, social influences, climate, sanitary conditions, age, sex, diet, that mould our patients?

The duty of rigid inquiry into all the conditions that determine an individual case of disease, becomes the more important the more limited our knowledge is of that particular disease; and if it can be shown that a disease known by a certain technical denomination may not be regarded as a nosological unit even as much as many other diseases that we are in the habit of dealing with familiarly, surely, before determining the value of a new drug or any drug in its treatment, we ought first to agree upon the nature of the cases to which we apply it.

Some time ago, a proposal, very laudable in the abstract, was made, to bring together from various sources and tabulate a large number of cases of pneumonia; and, by comparison, to deduce the results of treatment. It was not surprising, that no conclusions were arrived at; because, although there are certain features of resemblance between all cases of pneumonia, there are so many differences, independently of any bias of the individual observer, that we have not yet attained the common basis of observation. A case of pneumonia occurring in a person with a rheumatic taint, would not be the same as pulmonary inflammation affecting a person in whom no specific morbid diathesis was traceable. Pneumonia in a man inured to hard work, but accustomed to a gallon of beer a day, would demand different remedies, or at all events react differently to the same remedies that might be employed were the patient an overworked and underfed laundry-maid. Every practitioner of experience knows and acts upon this principle, and calls it tact. His daily intercourse with disease convinces him that, although his diagnosis becomes more and more precise, he cannot formularise his remedial effects in such a way as to justify the conclusions of a tabular statement. It is on such grounds that the attempt so often made to determine the value of a given remedy so uniformly fails; and it is for the same reasons, also, that it is

so dangerous to make positive statements as to the efficacy of a particular medicinal agent.

The pages of this JOURNAL have repeatedly referred to the uses of bromide of potassium in epilepsy. Statements in its favour have been contradicted by writers holding different views. The abstract question as to the value of bromide of potassium in epilepsy was put, as if the disease were a simple perversion of a normal function or a single well definable lesion, which could be neutralised by a given antidote. We have scarcely arrived at a sufficiently precise knowledge of the disease as yet, to reduce the question of treatment to so simple a denomination. We do not know nearly as much of epilepsy as we do of pneumonia, as to the local changes occurring in the body; but, although our knowledge is almost limited to the external phenomena, we are sufficiently advanced in our nosology, to affirm that the circumstances influencing and giving rise to the disease are as complicated as in any disease in the most complete nosological list. It would accordingly be scarcely fair, either to the disease or to the remedy to be tested, to take at haphazard a given number of cases characterised by the epileptic paroxysm, and to determine by the result whether or not the remedy deserved our confidence.

My objections to such a procedure would become still greater, if I were told that the cases were all of considerable standing, and justified the assumption that secondary cerebral lesions had already resulted.

We know of bromide of potassium, that it may be taken in large doses with impunity, and that it passes off by the kidneys; but we know nothing definite of its action on the nervous system. It behaves us, therefore, to be extremely careful not to reject an agent on insufficient grounds; but it is not so much my object to advocate the use of this agent, as to suggest that it does not follow that it is useless because in an asylum containing many confirmed epileptics it fails to produce the desired effects.

I am a firm believer in the general use of drugs in the treatment of disease; but I am habitually sceptical as to the effect produced by any given remedy in an individual instance, knowing the limitation of our powers of observation and analysis. I am not likely, therefore, to over-estimate any medicine; but, unless I have altogether wasted my time and opportunities, I have satisfied myself that there are many cases of epilepsy in which medicines not only benefit but cure the patient; and I believe, also, that in some—alas! but too few—it was something more than a mere coincidence that bromide of potassium arrested the disease. I am, however, equally certain that there are a large number of cases in which it is useless; and that epilepsy, like all other diseases, must not be treated as an unity, but regarded in all its aspects, and treated according to the various phenomena under which it may present itself. Bromide of potassium may be useful in one class of cases, but not in others; just as nitric or nitrohydrochloric acid benefits a certain class, and is useless or injurious in others. The iodides, again, are undoubtedly beneficial in some forms of the disease. Chalybeates, again, are required by some, and aggravate the malady in others.

It is not my wish, nor do I know that I could, with satisfaction to myself or the readers of the JOURNAL, classify the different forms, with the precision that I believe to be necessary; but of this I feel assured, that if we are to arrive at any definite and scientific result with regard to remedies in this particular disease, we must not lump all our cases together, and treat them all with the same remedy, especially with one the physiological action of which is as yet so little determined as that of bromide of potassium.

ON THE NATURE AND TREATMENT OF FEVER.

By A. B. STEELE, Esq., Liverpool.

[Read at the Liverpool Medical Institution, February 9th, 1865.]

I HAVE long been impressed with the conviction that the study of fever (especially with reference to its therapeutics) as pursued in the systematic treatises of authors, differs materially from the study of the disease as read in the book of nature at the bedside. I am disposed to attribute the confused, unsatisfactory, and conflicting conclusions to which the written history of fever leads the inquirer, to two principal errors:—first, that authors have laboured to establish a method of cure; and secondly, that they have based their systems upon a preconceived theory rather than upon clinical observance of the phenomena of the disease. To one or both of these mistakes, may be referred the erroneous but now happily exploded doctrines of Hamilton, Armstrong, Broussais, Clutterbuck, and others; it also explains the ephemeral reputation of those highly vaunted specifics, such as cold effusion, yeast, mineral acids, quinine, phosphorus, antimony, chlorine, mercury, and even alcohol, most, if not all of which, especially the latter, may be useful as remedies under certain circumstances, when given on rational principles, but all of which infallibly become doubtful or dangerous when regarded as specifics. Indeed I hope to be able to show that not only is there no specific for fever, but that, as Dr. Corrigan has observed, in the present state of our knowledge there can be no specific for this disorder.

In Dr. Watson's *Lectures*, we find the following allusion to the opinion of Pitcairn on this subject. "I do not" (says he) "like fever-curers; you may guide a fever; you cannot cure it. What would you think of a pilot who attempted to quell a storm? Either position is equally absurd. In the storm you steer the ship as well as you can; and in a fever you can only employ patience and judicious measures to meet the difficulties of the case." (Vol. ii, p. 843).

This sagacious and profound remark, in my opinion, comprises the whole principles of fever therapeutics. Although it guards us against useless interference and injudicious meddling with the operations of nature, it by no means sanctions or justifies a mere "do nothing" system, which is sometimes disguised under the specious title of "expectant treatment."

Without dwelling upon the now almost discarded doctrines of physicians of a former generation, I propose to point out what seems to me a want of practical soundness in the teaching of some authors of our own time. Let us appeal to Dr. Murchison, whose treatise on fever is considered one of the best and most recent text-books, and which undoubtedly contains a fund of valuable information on the subject of which it treats. In criticising the opinions of a physician of high repute and acknowledged ability, I must be allowed to say, that I do not for one moment venture to question the soundness or the success of his practice. It is the doctrines enunciated in his writings, and the inferences he deduces therefrom, to which I take exception, as calculated to confuse and mislead rather than to guide and assist the inexperienced and inquiring practitioner. Dr. Murchison's theory may be summed up as follows. (Pp. 15-16.)

1. The fever-poison enters the blood.
2. The nervous system (and particularly the sympathetic and vagus) is paralysed.

Here we at once detect what seems to me an important fallacy. In many cases of fever it is not paralysis, but the very reverse; namely, exalted or

unduly excited action of the nervous system which constitutes the predominant characteristic of the disease, as exemplified by the condition which has been designated "delirium ferox." Dr. Murchison completes his definition by particularising various morbid processes such as increased retrograde metamorphosis of the tissues, non-elimination, and so on, which are doubtless in accordance with sound pathology, but which, nevertheless, are after all too remote and perhaps too hypothetical to lead to a clear and safe basis for treatment, when compared with the conclusions drawn from clinical observation of the phenomena of the disease.

The indications which Dr. Murchison founds upon his theory are: to neutralise or to eliminate the poison, followed by other directions, which I have no difficulty in accepting as in accordance with sound practice, and which, therefore, require no special notice here; but I maintain that to send a student or an inexperienced practitioner to treat a case of typhus fever, with this notion impressed on his mind—namely, that his primary object is to neutralise or to eliminate a poison—is calculated to lead him altogether in a wrong direction. He would naturally first inquire, what is the nature of the poison, what its antidote, or by what special emunctory it is to be eliminated?

Like all doctrinaires, our author has his answer ready: "Typhus poison" (Murchison *On Fever*, p. 116), he tells us, "is some unknown compound of ammonia" (*ibidem*), and although he adds that it is perhaps premature or rash to hazard a conjecture as to its exact nature (p. 114); yet he founds upon this theory the use of mineral acids as neutralisers of ammonia in the blood (*vide* p. 265). A prominent direction for treatment, given by the author I am quoting, is, that "elimination is to be encouraged by maintaining the action of the kidneys, the bowels, and the skin." (P. 267.)

Now, I am at once prepared to admit that, under the skillful direction of the author himself, these indications may be, and no doubt are, so judiciously carried out, as in no way to interfere with the favourable progress of his patients; but to my mind, his theory is opposed to the teaching of clinical experience and to the common sense view of treatment which experience dictates. We have nothing approaching to a well founded record of the cure or arrest of typhus fever by the neutralisation of ammonia, or by the destruction of any other animal poison; and as to its elimination by purging or diaphoresis, this doctrine is opposed to the practice of the most experienced physicians of the present day—not excluding even our author himself—for it is but doing him justice to point out that in his directions for treatment, his practical experience, as I have already suggested, modifies or corrects the fallacious tendencies of his theories.

Purgatives in typhus, except in mild doses, and most cautiously and sparingly given, have been condemned by Graves, Corrigan, and others;* and as to diaphoretics, these remedies are as a rule contraindicated in typhus fever, for, as Dr. Corrigan has pointed out, "a crisis by perspiration is of all forms that which is most to be dreaded in maculated fever. I cannot," he adds, "explain this, but of the fact I have no doubt. I have such a dread of crisis by perspiration, that I would much rather see a case of

maculated fever considerably prolonged, than that the risk of crisis by perspiration should be incurred." Dr. Tweedie thus records his opinions on this point: "Insufficient grounds have been adduced for the employment of diaphoretics, which appear to have been suggested by observing the occasional termination of acute diseases by sweating. No one, however, I believe, ever witnessed a single case in which there was the smallest grounds for believing that the fever-poison was destroyed by such means." (*Lectures on Fevers*, p. 209.)

Dr. Murchison himself says: "After an extensive use of these remedies (diaphoretics), I cannot say that I have obtained very satisfactory results from them. Even when diaphoresis is produced, there is no necessary improvement in the general symptoms, while profuse sweating is often followed by increased prostration." With reference to elimination by the kidneys, a due consideration of the condition of the organs of the body, which we shall more particularly notice hereafter, renders it extremely probable that, in many cases, remedies which directly stimulate the kidneys would tend to increase congestion of those organs, rather than to excite them to increased action.

The fallacy of the eliminating mode of treatment is rendered still more apparent by reference to another disease, which has many points of analogy with typhus; I mean small-pox, which, like typhus, is the result of an animal poison introduced into the blood, has a specific eruption, and runs a definite course. No physician of the present day would, I presume, attempt to treat small-pox on the principle of elimination; the same may be said of measles, scarlatina, and other analogous febrile diseases. The conclusions to which the prolonged and extensive experience of Dr. Tweedie on this point has led him, is thus expressed in his own words: "It is apparent that fever when once developed can rarely be arrested; or, in other words, that the means of expelling the poison, or of depriving it of its noxious effects, have yet to be discovered. The duty of the practitioner, therefore, is to endeavour to guide the disease, and to prevent as much as possible injury to organs essential to life." (*Op. cit.*, pp. 211-12.)

Let us turn for a moment to another modern author of high repute, namely, Dr. Watson. His *Lectures on the Practice of Physic*, excellent as they are in all other respects, have nevertheless this objection, that fever is divided into weekly periods. This method of treating the subject presents a weak point; namely, that although from the nature of the case it will very often—perhaps most often—coincide with actual observation, yet when it is right, it is only right by accident, and although applicable to a large proportion of cases, may often also lead to a wrong conclusion in practice. The treatment of fever, as we shall presently see, is not to be regulated by the circumstance of its being the first, second, or third week of its duration, but by the state of each particular function day by day. "One case of fever may require as much wine on the second day of its attack, as another on the twentieth; and the bleeding or leeching that will not be borne in one case on the third day, will benefit another after a lapse of many days." (Dr. Corrigan *On Fever*, *passim*.)

There is another mode by which attempts have been made to lay down the principles of the treatment of fever; namely, by statistics, which appears to me most fallacious and untrustworthy. The ever varying rate of mortality from typhus at different periods of life, and during different epidemics, deprives that mode of calculation of much reliable value in determining the question of treatment, except on a very broad and general interpretation.

* Since this paper was written, the following remarks have appeared from Dr. Peacock of St. Thomas's Hospital. "In all cases of fever, I am especially careful to avoid purgatives in the early stages; and if some aperient must be given, employ those which are of the mildest character." "I have frequently seen, both in typhus and typhoid, diarrhoea established by the injudicious employment of purgatives, which it has been difficult or impossible to arrest." (*Lancet*, Feb. 11th, 1865, p. 145.)

This point is illustrated by the following record of fever statistics from Dr. Tweedie's lectures. The death-rate in the London Fever Hospital was 7 per cent. in 1851, 9 per cent. in 1862, and 20 per cent. in 1848. In Aberdeen it was 4 per cent. in one year, 18 per cent. in another year. In the Dublin hospitals for the last forty years, it has never reached 10 per cent. In Cork, the average was about 6 per cent. (*Op. cit.*, p. 200.)

The influence of age is shown by Dr. Murchison's tables as follows.

The death-rate of typhus—

Under 5 years	is	17.65
From 5 to 10	is	7.65
„ 10 to 15	is	4.95
„ 15 to 22	is	4.76
„ 20 to 25	is	9.5
„ 25 to 30	is	15.15
„ 60 to 65	is	55.68
„ 75 to 80	is	83.33

(*Op. cit.*, p. 221.)

From a due consideration of the foregoing figures, it is apparent that no safe deduction can be drawn as to the results of treatment from statistics, unless the ages are accurately stated in periods of not less than five years, a precaution not usually adopted by those who have written on this question. Herein consists the doubtful value of the conclusions at which Dr. Gairdner has arrived in his otherwise excellent paper on the Treatment of Typhus without Stimulants, published in the *Lancet*, March 12th, 1864, and which has been so ably criticised by Dr. Kennedy of Dublin in the same journal of January 7th, 1865.

Having thus endeavoured to point out the difficulties met with in the written history of fever, I proceed to show what may be learnt from actual observation at the bedside, laying aside theory and hypothesis, and reading from the book of nature. As the term fever has such a wide application in the practice of medicine, it is necessary to lay down some limitation in order that it may be clearly understood what disease it is that we propose to discuss. The continued fevers of this country as described by authors of the present day, are: 1, simple continued fever—the synocha, or short inflammatory fever of Cullen, which usually runs but a short course, generally terminates favourably, and scarcely requiring more than very ordinary attention; 2, typhus fever; 3, typhoid fever; 4, relapsing fever.

For practical purposes, it will be convenient to take typhus as a type of the rest, and to that form of fever the following observations will be specially applicable.

In this, as in all other diseases, the soundest basis for rational treatment is a clear and definite knowledge of the pathology of the disorder we have to deal with. We therefore proceed to inquire, what is fever? The differing opinions as to its nature may be divided into two great classes; first, those which consider fever a primary disease, and secondly, those which consider fever to have no existence as such, but regard it as the aggregated symptoms or the consequence of some local or structural lesions. The first of these two theories is that which is perhaps now most generally adopted, and which seems to me the true explanation of the nature of fever. That the second is untenable may, I think, be satisfactory demonstrated by reference to clinical records. I will endeavour to illustrate this point by relating two well marked examples, taken from the clinical lectures of Dr. Corrigan. The graphic description of what he observed in the Hardwick Hospital, has no doubt been verified in the experience of most practitioners who have seen much of fever.

“A man is seen comatose, lying on his back, with

muttering delirium, sordes on his tongue and teeth, pulse 132, skin thickly maculated, with great prostration of strength, involuntary stools, and sensibility so much diminished, that the eyelids remained immoveable, and the bladder had ceased to act. A crisis took place, and in less than two days, of all the above alarming symptoms, debility alone remained; the pulse became regular, the tongue clean, the sensibility natural, sleep returned, and not a trace or symptom of local or structural alteration was discoverable.

“It cannot be supposed that, in such a case, structural disease or local inflammation of several days' duration sufficient to produce this aggregate of alarming symptoms, could have so suddenly vanished.”

The second case affords still more decisive evidence on the point in question.

“A man, aged 54, admitted on the 27th February. He was in a state of great debility, and wandering in mind; his tongue dry and brown; pulse thready, 130; skin hot, dry, and pungent; thickly maculated; little or no sleep. On the 2nd of March, debility was greater, and stools passed under him. He still continued to sink, but without any complication. The pulse became scarcely perceptible at the wrist. Wine and stimulants failed to rouse him; and he died on the 10th March, the eleventh day after admission. The most careful *post mortem* examination failed to discover any local disease.”

If the foregoing examples are truthful records of what continually occurs in the clinical history of fever, the conclusion appears inevitable, that fever is to be considered as a primary disease of function, having an existence independent of, and capable of proving fatal without, any local or structural lesion.

In order to complete our definition of fever, we proceed to inquire what the functional lesion or lesions are which constitute its essential character; and, if we seek to determine this question from actual observation at the bedside, we see that, in a case of typhus fever, all the most important vital functions are simultaneously deranged. To present this more clearly, I have tabulated the symptoms of fever as follows, in accordance with the views of Dr. Corrigan, as taught in his *Clinical Lectures* already quoted.

Component Parts of a Case of Typhus Fever: Simultaneous Derangement of all the most important Vital Functions.

A. Derangement of the cerebro-spinal functions; or the lesion of innervation.

Indicated by prostration, want of sleep, delirium, stupor, coma, subletus, involuntary stools, retention of urine.

B. Derangement of the primary nutritive functions, including assimilation, secretion, and excretion; or the lesion of nutrition.

Want of appetite; thirst, and subsequent loss of desire for fluids; tongue dry or coated; skin harsh and dry; constipation or diarrhoea; tympanitis; urine scanty and cloudy.

C. Derangement of the circulatory functions; or the lesion of circulation.

The pulses of the wrist and heart.

a. Of the heart and large vessels.

b. Of the capillary system.

Lividity of surface; suffusion of conjunctivæ; macule; petechiæ; proclivity to sloughing of integuments—bed-sores; hypostatic congestion of internal organs.

The lesions here set down are to be regarded not merely as symptoms, but as component parts of the disease—deranged functions, which are to be treated by appropriate remedies. It should also be borne in mind that, although it is simultaneous derangement of the great primary vital functions which constitutes a case of fever, yet the proportions which these derangements bear to one another may not be exactly alike in any two individuals; and hence the definition which applies accurately to one case may not suit a second. Each case of fever will derive its distinguishing character from the function which presents the most marked deviation from health. In one case, the circulation is not much disturbed; but there may be great derangement of the function of innervation. In a second case, the cerebral and spinal system and intellect are scarcely at all involved; but the circulation sinks rapidly. In a third case, the function of nutrition, including secretion and excretion, is arrested or unduly excited; while, in a fourth, the nervous, circulatory, and nutritive functions may all be overwhelmed together. It is further obvious that, from the intimate relation and dependence existing between these several functions, one cannot be involved to a great extent, or for a continuance, without more or less implicating the other two. It is easy to understand how this simultaneous lesion of so many important functions must soon terminate fatally; one even—namely, that of the cerebral system—is sufficient of itself to cause death, as exemplified in delirium tremens.

This view of the nature of fever, if correct, affords an explanation of those artificial divisions of the disease into brain-fever, nervous fever, gastric or bilious fever, etc. It appears to me to divest the subject of much of the difficulty and obscurity in which students and practitioners must often have found themselves involved in attempting to reconcile the diversity and conflict of opinion which are encountered in perusing the voluminous treatises of fever in which the literature of our profession abounds.

I would here observe, that the foregoing observations may not be considered strictly applicable to typhoid fever, or, as it has been sometimes designated, in accordance with its special pathology, acute follicular enteritis; as, in this form of fever, there is very constantly if not invariably found to exist organic lesion of Peyer's glands, apparently favouring the opinion that in this particular disease the general symptoms are altogether dependent upon local organic lesion. I am not disposed to adopt this view, but believe that the apparent exceptional character of typhoid fever in this respect admits of such an explanation as to bring it fairly within the definition of fever already given. If time permitted, it might, I think, be shown that the ulceration of Peyer's glands, so often found in typhoid fever, is a secondary complication of the primary functional disorder; for it must not be forgotten that, in defining fever to be essentially and primarily a disease of function only, I do not ignore the important consideration that, in the course of a case of fever, organic lesions of a serious nature may occur, in many instances as the direct result of deranged function.

A retrospect of the foregoing analysis of fever gives us a key to the rational treatment of the disease, enabling us to a great extent to reconcile modes of treatment which, although widely different as to the precise remedies employed, may nevertheless each be rationally directed towards the fulfilment of the particular indications which may be present in a given case, and explaining how much that has hitherto seemed vague and conflicting may in reality be re-

conciled with fixed principles; and how it is that writers at different epochs may recommend even opposite treatment, and yet be correct in their observations and their practice.

Sydenham has pointed out that the type of fever is frequently changing, and that an acquaintance with the epidemic constitution of the time being is most important. He also adds that, when the type changed, he was frequently very unsuccessful in his practice until observation made him acquainted with the new type. Now, referring to the view we have adopted, it will be seen that the type of the fever can always be discovered by a careful analysis of the functions affected, the type being determined by the function most affected; and local disease, should it arise as a complication, will most frequently occur in the organs principally connected with the performance of that vital function, whatever it may be. Whether, therefore, we have to consider the type of a particular epidemic, or that of a special case, or whether it be a question of constitutional idiosyncrasy or the particular stage of the disease, we have fixed and unerring principles to guide us. No particular line of treatment can be laid down as appropriate in fever; but each lesion of function must be met by its appropriate remedy, to be regulated in application and degree by the extent of the lesion of function which it is intended to relieve.

In the practical application of the foregoing principles, it will be convenient to consider the lesions in order.

First, we take a case where the function most implicated is the cerebro-spinal—a lesion which, if long continued, terminates in death, either from the direct effect upon itself, or from implication of the functions of organic life. It is manifested by want of sleep or natural rest of the system, which, if extended over a few consecutive nights, is followed by delirium, coma, nervous exhaustion, and perhaps death. This want of sleep is to be regarded not as a mere symptom, but as a part of the disease, a lesion of function of the most serious consequence, and which, if continued, will cause death. Bearing this in mind, we avoid the dangerous error committed by some practitioners (of whom the late Dr. Clutterbuck was the representative), of considering the essence of continued fever to be inflammation of the brain, requiring active depletion for its remedy. Our efforts are directed to the regulation of a derangement of function, and not to the restoration of structural change. If want of sleep be the leading indication, rational means are to be adopted to meet it, by keeping the patient as quiet as possible, not darkening the room too much by day, and thus maintaining the natural alternation of day and night. Cold in some form is applied to the shaven scalp; and, if requisite, an anodyne administered at bedtime. As to the particular form of anodyne which is to be preferred, considerable difference of opinion exists. I have found in my own practice the tincture of henbane, in doses of two drachms, as recommended by Dr. Corrigan, frequently procure sleep; and, when it fails to produce the desired effect, it does not, so far as I am aware, give rise to the injurious effects which sometimes follow the use of opium, to which there is this objection, that it has a tendency to increase the derangement of the function of nutrition; and, in those cases where the digestive organs are much implicated, it is wholly inadmissible. In Dr. Watson's *Lectures*, the following significant observation of Dr. Latham is quoted. "I have certainly seen," says he, "twenty minims of laudanum produce tranquil sleep, from which the patient has awoke quite a new man; but I have also seen the same quantity produce a fatal coma, from which he has never roused.

Now," continues Dr. Latham, "since it is a fearful thing to strike a heavy blow in the dark, where the alternative is of such magnitude, it is safest and best to administer a small dose at short intervals." But surely it is better and safer still to select another remedy, which experience has shown will fulfil the indication with perhaps certainty, and with infinitely less risk—probably, indeed, without any risk at all, even when given in full doses. At the same time, I would by no means venture to assert that opium is to be altogether dispensed with in the treatment of fever, but would urge that it should be employed with extreme discrimination and caution. Where other means fail to procure sleep, four or six leeches may be applied to the temples, as recommended by Dr. Corrigan, as an anodyne, upon which he places more reliance than upon any other, and this even when the pulse is weaker than natural; for, as he observes, we need not fear to take a small quantity of blood from the capillaries, for they very soon accommodate themselves to the trifling loss, and the general effect upon the system is scarcely felt; besides which, we can, quite consistently with our principles, give stimulants to support the general circulation, while we are relieving local congestion by moderate depletion from the capillaries.

The internal administration of chloroform has been recommended by the author just quoted; but I cannot from personal observation confirm its efficacy. I have met with cases in which this lesion of innervation, indicated by persistent restlessness and loss of sleep, has resisted every means that could be suggested, and which have invariably proved fatal. In such cases, although we may be able to meet the lesion of circulation by stimulants, yet, unless we can at the same time regulate this lesion of innervation by inducing sleep, the patient is sure to die. It is probable that, from a want of due consideration of this circumstance, the apparent failure of the stimulating mode of treatment has often been misinterpreted.

If stupor or coma come on, or be threatened, blisters may be applied as a means of rousing the patient. A very convenient mode of applying them to the scalp is in broad strips across the top of the head, instead of in the circular form commonly used, which does not lie so flat, or keep on so well.

One of the indications of the lesion of innervation is *subultus tendinum*, to be treated on the principles already laid down. Whether this peculiar condition of the nervous system is purely a lesion of function, or whether it depends upon congestion or structural alteration of the cerebro-spinal system, has not been determined. As collateral evidence in favour of the view that the general symptoms of fever are independent of structural lesion, I may here quote the words of Dr. Watson, who, in speaking of the cause of coma, remarks: "Physicians have diligently attempted its solution by examining the dead brain. I cannot tell you," he adds, "how often I have looked, and looked in vain, for some palpable disorganisation, or some effusion implying pressure." (*Op. cit.*)

We next proceed to consider the lesion of the elementary function of nutrition, upon which both animal and vegetable vitality mainly depends, including assimilation, secretion, and excretion. The symptoms are, loss of appetite, first for food, and afterwards loss of desire for fluid, which, in severe cases, succeeds to the thirst which exists in the earlier period of the disease, and is an aggravated degree of the same lesion. The tongue is dry or coated; sordes on the teeth; harsh, dry, and hot skin; derangement of the alvine discharges; constipation or diarrhæa; tympanitis, etc.; and morbid state of the urine. It

is scarcely necessary to occupy time in dwelling upon the obvious remedies by which these indications are to be met; but I may venture to allude to some important points.

First, as to the use of purgatives: these, as already noticed, should be used very sparingly, and, when required, should always be of a mild character. Enemata may often be advantageously substituted. Then as to mercury: in cases where there is a dry coated tongue, absence of thirst, urine cloudy and of low specific gravity, small doses of a mild mercurial, such as blue pill or grey powder, will generally be most useful in restoring the deranged function of nutrition; and, in combination with the alteratives, diuretics may sometimes be advantageously combined.

In this condition of a more or less complete arrest of the function of digestion, we must use much caution not to overload the stomach with nutriment of any kind. Milk, beef-tea, and wine or brandy, in judiciously regulated quantities, guided to a great extent by the desire for them evinced by the patient, is generally all that is required, or that, in fact, can be given without danger of causing still further derangement of the digestive and assimilative functions. As, together with other arrested functions, that of the skin is a prominent symptom, indicated by the dry harsh feeling communicated to the hand when applied to the body of a fever-patient, we might, *a priori*, conclude that diaphoretics are indicated, and that a renewal of perspiration might be considered a favourable symptom. So far, however, is this from being the case, that crisis by perspiration, as has already been noticed, is much to be dreaded in typhus. It is not sufficient to abstain from giving diaphoretics, but we must also avoid over-heating the patient in any way. I have known a case of typhus which was progressing favourably, and where recovery might have been confidently predicted, but where, from the obstinacy of the patient and his friends, in opposition to the directions of his medical attendant, blankets and bedclothes were heaped upon him, and a copious perspiration, which ended fatally, was the result. As Dr. Corrigan has emphatically remarked: "Popular knowledge, or rather ignorance, confounds maculated or typhus fever with synocha or short inflammatory fever; but the copious perspiration that will cure in the latter will kill in the former."

The next lesion we have to consider is that of the function of the circulation, of that of the heart and large vessels, as indicated by the pulse at the wrist and the impulse of the heart; and of the capillary system, shown by lividity of the surface, injection of the conjunctive, macule or petechiæ, and proclivity in the integuments to superficial sloughs from pressure. These indications, it is to be borne in mind, are not mere symptoms, or local derangements only, but external indications of the state of the circulatory system as a whole; so that we have to combat a lesion, not of a particular organ or structure, but of a function universally diffused through the whole system. The degree of derangement of the capillary circulation, as shown on the surface by the extent and colour of the macule, is an indication of the condition of the same function throughout the system. Thus rose-coloured macule indicate activity of the capillaries, and are, therefore, more favourable than the darker coloured spots, which are the result of an enfeebled circulation. Petechiæ, or effusions of blood from the capillaries, are signs of greater danger still. The treatment appropriate to this particular lesion is so obvious, that it will at once be anticipated that stimulation and support are the only means upon which we can rely. The best remedy, undoubtedly,

is alcohol in some form or other. Here is the solution of the much contested question as to how and when stimulants are to be given in fever. Alcohol is the specific remedy for lesion of the function of circulation involving the cardiac and the capillary systems; so that the state of the pulse and the changes in the colour of the maculae are the symptoms by which we judge as to the necessity of continuing, decreasing, or augmenting its dose.

If this lesion of the circulation be that of depressed action, alcohol must be given, whatever may be the derangement of the other functions. Consequently, whether there be delirium or not, whether the abdomen be flaccid or tympanitic, whether the tongue be dry or moist, clean or coated, whether it be the first, second, or third week of the fever, are conditions which have no influence whatever in deciding the question. The amount of depression as indicated by the lesion of circulation, modified, of course, by the age, constitutional powers, and previous habits of the patient, are the only circumstances which have to be considered in reference to the use of stimulants. Other forms of stimulants may be sometimes given, of which probably ammonia is the most useful; and here we may remark, that practical experience is at variance with the theory that typhus poison is a compound of ammonia.

It is interesting to notice, that the treatment of typhus by stimulation is by no means a new doctrine. Dr. Trotter, who wrote in 1794, and whose graphic description of the disease shows him to have been a practitioner of much observation, was so impressed with the value of stimulants in typhus, that he sums up his account of the disease with this motto:

"Nil desperandum, Baccho duce et auspice Baccho."

His sagacity had also detected the fallacy of trusting to specifics, as the following brief quotation will show. "Of a febrifuge power residing in antimony, our observation and experience do not enable us to speak in confirmation; nor do we suppose that such a power is to be found in any other medicine whatever." (*Medicina Nautica, passim.*)

Dr. Stokes of Dublin, writing in 1839, says: "I feel certain, humiliating though the confession may be, that the fear of stimulants in fever, with which I was imbued, was the means of my losing many patients whose lives would have been saved, had I trusted less to the doctrine of inflammation and more to the lessons of experience given us by men who wrote before the times of Bichat and Hunter." (*Dublin Journal of Medical Science*, March 1839.)

If the view thus taken of fever be correct, it explains how combinations of remedies may be regarded in those cases where several functions are simultaneously deranged, and that the treatment is to be varied according to the function chiefly affected, and the degree to which it is involved. Thus leeching, cold to the head, or hyoscyamus, may be requisite for lesion of the cerebro-spinal system, mercury for the derangement of the nutritive function, and alcohol for failure of the circulation. So that also the details of treatment may not be alike in any two cases of fever, yet the principles upon which they are founded are fixed.

From this it appears conclusive that, as before mentioned, fever is a disease for which there can be no specific. In the words of Dr. Corrigan, we may conclude: "To suppose there can be any such thing as a specific in fever, would be to claim that the same remedy had equal and opposite powers; that it would highly stimulate the function of circulation in one case and depress it in another; that it would calm down an excited brain into sleep, and equally

restore it from coma to wakefulness; that it was a remedy of universal power, equally applicable to lesions of all functions, and to such lesions whether arising from increased action, debility, or mere excitement."

ON PUERPERAL FEVER.

By T. SNOW BECK, M.D. Lond., F.R.S., Member of the Royal College of Physicians, London.

[Read before the Obstetrical Society of London, February 1st, 1865.]

[Continued from p. 431.]

At first view, these cases present little difference from many others which have been recorded; but, on closer examination, I think they point to two important facts: the pervious condition of the uterine sinuses, by reason of the want of a firm and persistent contraction of the uterus; and the absence of all inflammatory product, save that observed on the peritoneum. They thus appear to give a decided negative to the opinion that puerperal fever was caused by uterine phlebitis, lymphangitis, endometritis, metritis, or other similar inflammatory affection of the uterine organs. For, with the exception of the inflammation and exudation of the peritoneum, no product of inflammation was any where discovered, after a careful and even microscopical examination of the various tissues which compose the uterus. All of these tissues were in a perfectly healthy state. And I feel considerable confidence in this result, as repeated dissections and examinations of the gravid uterus have made me familiar with the healthy appearance of the tissues which enter into its formation.

But inflammation of the peritoneum, with copious exudation into its cavity, have been long recognised as the morbid appearances most usually observed in this disease. I am not aware, however, of any case where the uterus has been so fully examined, and wherein all the tissues were found perfectly healthy; especially when the woman had survived a period sufficiently long after the commencement of the attack for any inflammatory process to become developed, had this been an essential part of the disease. The total absence of any sign of inflammatory product in the uterus itself, whilst the symptoms during life so well characterised the disease, appears to show that the disease has some other cause than these inflammations. The result of the examination of the uterus, moreover, is opposed to some doctrines supported by the highest authority, and furnishes evidences which are contradictory to the opinions expressed by Professor Cruveilhier and supported by Dr. Robert Ferguson. In the opinion of these eminent observers, the internal surface of the uterus is compared to a vast solution of continuity, the muscular tissue being every where exposed; and the gaping orifices of the sinuses are also compared to the open-mouthed vessels of an amputated limb. But the inner surface of the uterus was found every where covered by a soft membrane, which contained all the microscopic elements of the usual mucous membrane. Numerous shreds extended from the inner surface, and gave it the appearance as if the inner portion of its thickness had been torn away. Still the muscular tissue was every where covered by a soft membrane, the surface of which was further covered by the usual red mucous discharge which follows childbirth. Some slight exception must, however, be made on account of that portion to which the placenta had been attached. The membrane was here thicker and firmer than elsewhere, and distinct fibrous tissue entered into its formation. It appeared, in fact, as if a very thin portion of the pla-

centa had remained attached to the surface of the uterus. The red mucous discharge did not appear so intimately adherent to the surface, and did not present the appearance of being secreted by it.

At this part of the surface, many open orifices were perceived, which led directly to the sinuses in the substance of the uterus; and, as they permitted fluids to pass along them in a direction contrary to the course of the circulation, it is inferred that fluids might readily pass along these canals, and injuriously impregnate the general system. The uterus in this condition, then, may be compared to the healing surfaces of an amputated limb, seeing that the vessels which lead from the open orifices were alike pervious in both. But this comparison is not just, inasmuch as the uterus is in an abnormal state. The essential part of the comparison does not rest upon the open orifices which are found alike on the surface of the uterus and the surface of an amputated limb, but on the vessels which lead from these orifices being alike pervious in both. When the uterus is firmly contracted, all circulation in the sinuses is effectually prevented; and the same will occur in an organ where the contraction is not so complete, but where the blood has become coagulated. In either of these instances, a comparison between the condition of the vessels in a uterus after recent childbirth, and the vessels of an amputated limb, will cease.

If it be said that there is a great similarity between the vessels of an amputated limb and the vessel of an uterus after recent delivery in those women who have died from puerperal fever, the comparison will hold good. But, it should be remembered, the comparison is here instituted between a natural condition of the vessels in the amputated limb, with an unnatural state of the vessels of the uterus. For it will be conceded that the lax condition of this organ which permits the general system to be injuriously impregnated, and allows fluids to circulate within their canals, is not the natural nor proper condition in which the uterus ought to be; and I think we can go further, and say it is not only a condition which ought not to be, but is a condition which may, in the large majority of cases, be prevented.

It is singular in how many recorded instances of puerperal fever the uterus is described as "large, uncontracted, soft, and flabby," as "very large and ill contracted," or similar descriptions. And it has long been remarked, that women who suffered from hæmorrhage during or after the birth of the child were specially prone to be attacked with puerperal fever; or, as Dr. Denman remarked nearly a century ago, "It is likewise worthy of observation, that those women who have lost much blood at the time of delivery are more liable to this disease than others, and that it is much more fatal to them." (*Essay on the Puerperal Fever*, 1768, Syden. edit., p. 51.) Which is only another way of stating that the uterus was large, flabby, and uncontracted; seeing that it is admitted that these hæmorrhages mostly arise from this condition of the organ.

It is well known that most recent authors have attributed this disease to a diseased or vitiated condition of the blood; but the opinions as to the means by which this alteration has been produced have been very various. Dr. Simpson says: "That the original focus of contagion in them (cases of puerperal fever) was to be traced to the diseased blood and tissues of the mother who was first delivered and first attacked; that her blood had affected the infant which she carried within her; and that probably the vaginal secretions and discharges from this said patient during labour had unhappily formed the virus or material, which had been unwittingly car-

ried by Dr. Moir so as to affect his other patients." (*Obstetric Works*, vol. ii, p. 20.) M. Cazeaux remarks: "In my opinion, the blood in this disease has undergone so profound an alteration as to account for all the accidents, and for the usually fatal termination of the disease. I do not hesitate to say that, in certain cases, they (the alterations) may be carried to a point at which they will produce a transformation of blood-globules into pus-globules; and that without a wound, without phlebitis, without any lesion of the solids." (*Bulletin de l'Acad. Impériale de Méd.*, vol. xxiii.)

These, however, are only opinions, and scarcely meet the facts. Dr. Simpson does not tell us how the blood and tissues of the mother who was first attacked became diseased—for this cause was the original focus of the whole; and M. Cazeaux fails to inform us by what means the blood-globules become transformed into pus-globules, nor refer to any evidence to show that such a transformation in the circulating blood is even possible. These opinions, moreover, fail to explain how a woman, previously in good health, may be delivered, and recover from the first effects of the labour, and yet fall a victim to the disease within a few hours afterwards; and all this occur in sporadic cases.

Dr. Robert Ferguson, in his valuable *Essay on Puerperal Fever*, gives the following propositions, which it may be well shortly to examine:—1. The phenomena of puerperal fever originate in a vitiation of the fluids. 2. The causes which are capable of vitiating the fluids are particularly rife after childbirth. 3. The various forms of puerperal fever depend on this one cause, and may readily be deduced from it. In proof of the first proposition, he quotes the experiments of Gaspard and Cruveilhier, wherein symptoms analogous to those of puerperal fever were produced in animals by injection of putrid pus and similar fluids into the veins; by cases where the placenta had been retained, had putrefied, and symptoms similar to those of puerperal fever followed; and by referring to the effects of dissection-wounds, the bite of the viper, and some acknowledged diseases of the fluids. In support of the second proposition, he adopted Cruveilhier's opinion, which he thus expressed: "That after childbirth the womb is like an amputated stump; and that it has a reparative process to perform, which, being disturbed, permits the large gaping vessels to spread in the blood noxious secretions which they have imbibed." (P. 80.) Dr. Ferguson further considered that the blood "may be vitiated by injuring the solid vessels mechanically; thus creating inflammation, which inflammation furnishes the matter that is conveyed into the torrent of circulation to infect the blood." (P. 75.) But he has not, so far as I can find, adduced any facts to confirm this opinion: whilst, under the third proposition, many cases are included which can scarcely be acknowledged as cases of puerperal fever. For example: "In the epidemic of the winter of 1827-28, this form (peritoneal affection) was so prevalent along the banks of the Thames, that, being worn out with incessant calls to visit the patients at their own houses, I directed the matron of the hospital to send, in the first instance, to all complaining of abdominal pain, two doses of Dover's powder, each containing ten grains; one to be taken immediately, and the other in four hours; when, if, notwithstanding, the symptoms should persist, they were directed to send for me. After this, I think I had no occasion to visit one in five of those afflicted, as they did not require any other treatment." (P. 16.) "So invariably, for example, does a dose of the house medicine (or salts and senna), after causing violent pain and purging, bring on metropéritonitis, that I

have long forborne the use of this drastic irritant, as the routine dose, given on the third day." (P. 101.) I think it will be admitted that a dose of salts and senna will not produce, nor two doses of Dover's powder cure, so serious a disease as puerperal fever.

The facts previously adduced will, I submit, show that the grounds upon which the second proposition is founded—viz., that the interior of the uterus is like an amputated stump—are not tenable. And the same may be said of the opinion that the solid vessels of the uterus are injured mechanically; for the uterine sinuses consist solely of the delicate inner membrane of the veins, which is connected to the muscular tissue of the uterus by a fine cellular or connecting tissue. They do not present a solid resisting substance, which would be liable to be mechanically injured during the contraction of the muscular tissue of the uterus. That the muscular tissue may be injured by the violent expulsive efforts to which it is sometimes liable—that it may subsequently inflame—that fever and even death may follow such injury—will not, I think, be doubted; but, I would submit, this can scarcely be considered to be injury "of the solid vessels mechanically".

Thus, whilst I feel I must dissent from Dr. Ferguson on the original causes which produce this disease, I freely assent to the proposition that the phenomena of puerperal fever originate in a vitiation of the fluids, as well as with the following observations. "Neither does the malady depend solely on primary inflammation of the uterine veins; for these are, in a great number of cases, perfectly healthy. The cause, therefore, of puerperal fever is, I think, simply a vitiation of the blood, which cause is demonstrably sufficient to produce all their phenomena; that phlebitis, or peritonitis, or metropéritonitis, are only secondary effects of this one cause. For, if any one or more of these be assumed as constituting the essence of puerperal fever, abundant examples may be found of puerperal fever in which the cause fixed on is absent. Thus, to the believers in the identity of peritonitis and puerperal fever, we can show puerperal fever in a perfectly healthy peritoneum. To those who insist on inflammation of the uterine veins as constituting puerperal fever, we can show the genuine disease without this condition." (Page 81.)

If it should be shown by further observation that the sinuses of the uterus remain pervious in cases of puerperal fever, then I think the various phenomena observed in this disease may be satisfactorily accounted for. And the following remarks by M. Dance, in his valuable papers on *Uterine Phlebitis*, which I did not see until the previous observations were made, confirm me in the belief that the sinuses are pervious. He gives the following as the result of some observations made "on the bodies of women who died a few days after their confinement". "If we throw an injection, even a coarse one, into the inferior cava, above the emulgent veins, it directly flows in abundance into the cavity of the uterus, and soon escapes at the vulva—an important fact, which tends to prove that the large veins are quite open in the cavity of the uterus after the confinement, and freely communicate with the large veins of the abdomen; which serves to explain the propagation of inflammation from the one to the other. If we afterwards examine the internal surface of the uterus, at the part which corresponds with the insertion of the placenta, we directly perceive that it is principally at the points where the matter of the injection has escaped. Large fragments of this matter are in part imbedded in the walls of the uterus, and in part project into its cavity. On detaching these, after cleaning the sur-

face, we immediately perceive the entrance of the uterine sinuses—that is to say, a certain number of venous orifices, of variable size, some of which might admit the end of the little finger, separated from each other by bands in appearance muscular, and situated at the bottom of a small depression, and which appeared closed by a crescent valve. On raising this membrane, which is nothing more than the natural membrane of the veins divided obliquely, we penetrate into the large canals, which, after a short and oblique course, communicate with the innumerable veins situated in the walls of the uterus. It follows from this, that, after the separation of the uterus, large and numerous channels permit the inflammation to extend into the uterine veins, which veins themselves present the conditions favourable for the propagation of the inflammation." (*Archiv. Gén. de Méd.*, 1828, p. 480.) Hasse also remarks: "It (phlebitis) develops itself with uncommon rapidity whenever, after expulsion of the fœtus and of the placenta, the uterus does not contract properly; so that an extensive raw surface, with open-mouthed veins, is exposed." (*Pathol. Anat.*, Syden. edit., p. 28.) Dance certainly does not say that these observations were made in cases of puerperal fever; but it appears not improbable that such was the case, from the statement that the women died a few days after their confinement; and, whilst I could scarcely admit that this pervious condition of the uterine sinuses explains the extension of inflammation from those vessels to the abdominal veins, I am glad to have such confirmation of the fact that in these the uterine sinuses are pervious; and further, as remarked by Hasse, that this pervious condition occurs when the uterus does not contract properly.

Such a condition of the vessels as this closely represents the state of the vessels in an amputated limb; and it can be matter of little surprise that the symptoms and pathological appearance which so frequently follow in women where this condition of the uterus exists should bear so close a resemblance to the symptoms and pathological appearances observed in cases where death takes place after amputations or other surgical operations. The close analogy between these two conditions has been most ably traced by Dr. Simpson; but I cannot avoid repeating that, in contrasting these states, a natural condition of an amputated limb has been compared with an unnatural state, an uncontracted state of the uterus after delivery; which to my mind vitiates the whole ground of comparison.

With regard to the symptoms which may follow deleterious impregnation of the general system through the introduction of noxious fluids into the veins, the experiments of Gaspard and Cruveilhier upon animals have placed it beyond doubt that phenomena analogous to those of puerperal fever may be induced by the introduction of putrid pus and similar fluids into these vessels. The latter eminent pathologist has further observed, that the quantity of the injection, whether in artery or vein, and the vigour of the animal, modified the result in the most singular way; a small quantity being eliminated by intestinal or urinary secretions, while a large dose killed.

Taking all these circumstances, then, into consideration, we may consider that where the uterus is very lax, and admits of a ready flow of noxious fluids through the sinuses, we will have the phenomena, occasionally observed, wherein a previously healthy woman is stricken down, as if by some fell pestilence, in a few hours; or, as Dr. Demman expressed it in 1768: "The progress of the disease is sometimes extremely rapid. Instances have occurred where women have died even within twenty-four

hours of the first attack; and I have seen a few who never grew warm after the rigor."

To the same class of cases we may refer Dr. Armstrong's "peculiar congestive disease", where "the shock in some instances is so great that the secretions are all suspended, and the patient sinks with rapidity;" and Dr. Mackintosh's cases of "intense inflammation", where "she shivered about eight hours after delivery, and continued to sink, having pain in the epigastrium and tumefaction of the abdomen, with diarrhoea. Coldness over the whole surface of the body preceded her death, which followed in a few hours."

When the amount of deleterious fluids introduced into the system is smaller in quantity, there will be induced cases of puerperal fever, which are too frequently observed, and where the system, after a vain struggle with the poisonous infection, succumbs in a few days or a few weeks; the chief morbid appearances found in the body being extensive peritonitis of a peculiar character, with copious exudation of soft friable lymph and much serosity. The course of some of these cases would also appear to indicate that the poisoning took place in successive periods, in the intervals of which the system partially recovered, and the symptoms became alleviated.

It is probable that the effects of uterine phlebitis, metropéritonitis, distension of the lymphatics with purulent fluids, etc., may be the result of a yet smaller amount of deleterious infiltration; the effect produced being more local; in many cases the blood being coagulated, and the fibrine softened; in other cases, local inflammation is set up as a consequence of these first changes.

In other cases, again, where the amount of poisonous infection is still further diminished, we have examples of low febrile conditions extending over an indefinite period, with purulent infiltration occurring in various parts and organs of the body, "*à l'insu du malade et du médecin*"; whilst, in yet smaller increments, this vitiation of the fluids may induce a long continued febrile state, accompanied by troublesome and anomalous symptoms.

It will readily be conceded, also, that each of these states may be much influenced by a variety of concomitant circumstances—as the original constitution of the female; her state of health at the time; the character of the fluids secreted by the interior of the uterus; the effect of any severe loss of blood; any depressing influence of the mind, or of the situation in which she is living; her habits of living; the existence of any diathetic diseases, epidemic influences, etc. These, and a variety of other causes accidental at the time, may induce a great variety of diseased states and many pathological appearances after death, which may well lead to that utmost inextricable conflict of opinion which characterises the literature of this disease. Nor will it excite surprise, if the effects are most frequently observed and most fatal amongst the ill-clad, ill-fed, ill-nourished, and sometimes improvident mothers of families, of spare means, who form the majority of those received into our maternity charities.

In this sketch of the principal phenomena observed in the different cases of puerperal fever, no reference has been made to the subject of contagion, or to the occurrence of epidemics. On this point, Dr. Churchill has remarked: "The opinions of those most experienced in the disease vary very much. Drs. Hulme, Hey, Armstrong, Dewees, and Campbell in their works deny its contagiousness; Dr. Gordon, Professor Young, Mr. Coely, Drs. Ramsbotham, Rigby, Lee, and Copland, etc., affirm it. Dr. Hamilton thinks it so contagious that it may be communicated

to a third person." (*Essays on the Puerperal Fever*, Syden. edit., p. 38.) And I must admit that I have grave doubts on both these subjects. To no subject does the truism, that *post hoc* is not always *propter hoc*, apply with greater force than to the present. For example, a physician of Leith examines the ovaries of a woman who had died of puerperal fever in the lodgings of another physician in Edinburgh. It does not appear that he had any other relation to the case than this. The three next cases of labour he afterwards attended in Leith were attacked with the disease. A medical gentleman, after having lost several cases of puerperal fever, got rid of the disease in his practice by changing his clothes and using chloride of lime, etc. But again it returned, after wearing a pair of unfortunate gloves he had previously worn. A general practitioner lost many patients from puerperal fever. He delivered no more cases for one month; but the first patient he attended afterwards was attacked with the disease, and died. "I rather think," observes Dr. Churchill, "this proves too much." (P. 39.) It does appear incomprehensible that a disease which is not communicated to the attendants of those suffering from it, or which is not communicated from one woman to another in an adjoining bed in our lying-in hospitals, should be, in occasional cases, so virulently contagious. As Dr. Murphy remarks, "Puerperal fever selects its victims. In the same hospital, and in the same ward, it will not extend from bed to bed, but is found scattered in different directions." (*Lectures on Midwifery*, 1862, p. 681.)

Another set of cases may probably admit of a different explanation. Mr. Robertson of Manchester relates that sixteen cases of puerperal fever occurred in one month in the practice of one only out of twelve midwives in connexion with the lying-in hospital of that town; the disease being limited entirely to her patients, but not limited to one particular district, being scattered through different parts of the town. "Again, little more than half of the thirty women delivered by this midwife during the month before mentioned took the fever. On some days, all the women she delivered escaped; on other days, out of three or four, one or more of them were seized." (P. 441.) If the disease was so eminently contagious, why did fourteen women escape, and sixteen be attacked with the fever in the same month, and all in the practice of this one midwife? May it not have arisen from the mode in which this midwife managed her patients—in a manner similar to the anecdote related by the late Dr. Merriman? "During the time that I held the office of physician-accoucheur at the Westminster General Dispensary, of the twelve stated midwives belonging to that charity, one in particular was very frequently in the habit of sending to me for assistance in consequence of retention of the placenta; so that I was called by her to such cases nearly as often as by all the others together. I had often endeavoured to discover the reason why this midwife should be so unfortunate in her patients; but I could obtain no satisfactory explanation of the frequency of the occurrence in her practice. A few years after I had retired from the dispensary, the daughter of this midwife requested that I would give her some instructions in midwifery; in the course of which I strongly pointed out the propriety of leaving the expulsion of the shoulders to nature, after the birth of the head, as preparatory to a proper contraction of the uterus, and more ready and complete separation and expulsion of the placenta. When I next saw her, she told me she had mentioned to her mother what I had taught her on this subject, and that her mother had said 'she thought it the greatest nonsense in the world to allow the poor

woman to wait for a pain to deliver the shoulders, when it was possible to finish the labour, by a little assistance, without delay. For her part, she was always used to bring the child as soon as the head was born; and so she should still do.' The anecdote at once explained the mystery; and I marked it down, as an excellent illustration of Mr. White's judicious and convincing remarks." (*Synopsis of Difficult Parturition*, p. 298.)

In other examples, it is more than probable that the disease communicated was some acute specific disease. "Dr. Collins mentions an instance in which a patient was admitted into the Dublin Lying-in Hospital, labouring under a bad form of typhus fever. Two puerperal females, who occupied the adjoining beds, were attacked with puerperal fever, and died. In another instance in the same hospital, a similar accident happened. A patient labouring under typhus fever was admitted into a small ward of the house, which contained only four beds: all the three other women were attacked with puerperal fever, and two of the three died." "In the Dublin Lying-in Hospital, a case of typhus was brought in by mistake, and immediately dismissed. Puerperal fever appeared in forty-eight hours afterwards, although the hospital had been free from it for a year before." (Dr. Murphy.) In these cases, however, the disease was communicated from bed to bed, exactly in the way we know typhus fever to be communicated; whilst we further know that puerperal fever is not communicated from individual to individual, "but is found scattered in different directions."

In an important communication to this Society, Dr. Tilbury Fox showed, from cases which occurred at the General Lying-in Hospital from 1833 to 1858, both inclusive, that typhus fever, typhoid fever, remittent fever, scarlet fever, erysipelas, abscess in the breast, constipation, after-pains, muscular irritability, etc., have often been included under the term puerperal fever. (*Trans. of Obstet. Soc. of London*, vol. iii, p. 368.) Then we have the remarkable epidemic recorded by Dr. Ferguson, which prevailed along the banks of the Thames in the winter of 1827-28, and which only required for its successful treatment two doses of Dover's powder; and the still more remarkable statement of Dr. Tyler Smith: "It (puerperal fever) would not so often happen, if all accoucheurs recognised the fact that erysipelas, typhus, scarlatina, small-pox, hospital gangrene, putrid sore-throat, diphtheria, the *post mortem* and other poisons, were excessively prone, if brought near the lying-in woman, to originate puerperal disease. He did not question but that any of the agents which produced zymotic maladies might cause puerperal fever." (*Obstet. Trans.*, vol. iii, p. 403.) Here seven and more distinct specific diseases are said not only to alter their nature when communicated to a lying-in woman, but, by a singular agreement amongst them, they all undergo the same identical transformation. Such a conclusion, however, is opposed to all the known facts relating to the history and course of acute specific diseases—however prone the puerperal female may be to take on any of these diseases, or be influenced by epidemic causes, when brought into contact with them.

These examples might be largely amplified; but I feel they are sufficient to show that the observations require further clinical examination, which can alone enable us to diagnose and separate from each other the various diseases at present included under the one term puerperal fever; the only apparent link being, that they attack the female during the puerperium.

[To be continued.]

WE beg to remind the members of the Association that the annual subscription for 1865 became due on January 1st. Payment of the same can be made either to the Honorary Secretaries of Branches; or to the General Secretary, T. Watkin Williams, Esq., 13, Newhall Street, Birmingham.

British Medical Journal.

SATURDAY, MAY 6TH, 1865.

A NEW HOSPITAL AT LIVERPOOL.

WE have received a copy of the Second Annual Report of the Hospital for Cancer and Skin-Diseases, founded in 1862 in Liverpool; Lord Stanley appearing as President, Mr. J. Seaton Smyth as Honorary Surgeon, one Mr. Sked as Treasurer, and Dr. Stookes, with five other gentlemen, as Committee. If we are to believe the Report, the institution is already a very flourishing one; and, as neither "fees nor letters of recommendation" are required, "the institution" (as we are assured) "has been a charity in the purest and fullest sense of the term." A discriminating public have, it appears, so fully entered into the views of the benevolent institutors, that Mr. Sked, the Treasurer of the Cancer Hospital, and Manager of the Mercantile and Exchange Bank, now says that the establishment must be enlarged. At present, if we are rightly informed, the hospital is represented by some back or outlying premises of the benevolent surgeon who does gratuitously its medical operations. Mr. Smyth's operations, indeed, appear to exceed the ordinary bounds of medical benevolence, and, therefore, should be especially recorded. Says Mr. Sked, "As the fact may not be generally known, the Treasurer" (*i.e.*, Mr. Sked) "takes this opportunity of stating that Mr. Smyth has himself contributed to the foundation, establishment, and necessary expenses of the hospital, upwards of £500." It is not, however, clear to us, from the Report, whether the £500 has been contributed to the hospital which is to be, or upon the building which at present represents it.

The "Medical Report" (which, by the way, bears no signature) is lengthy. It opens with the announcement that when "this institution was established, there was not one out of the metropolis specially devoted to the treatment of these diseases." The word *these* reminds us of the story which says, "This Turk he had an only daughter"—no Turk or diseases having been before alluded to in the Report or story. *These* diseases, however, we find, on referring to the Appendix, to be cancer and every kind of skin-disease, *plus* spina bifida, housemaid's-knee, morbus coxarius, hydrocele, fistula *in ano*, club-foot, varicocele, fatty, fibrous, and cystic tumours, phi-

mosis, etc.; so that, it appears, all is fish that comes to the net; or, as quaint old Spenser, in his *Faëry Queen*, says:—

“Als at his back a great wyde net he bore,
With which he seldom fishéd at the brooke,
But used to fish for fooles on the dry shore,
Of which he in faire weather wont to take great
[store.]”

The Report is a specimen in its way; and we especially allude to it, in order that those of our profession, who may feel inclined to emulate the philanthropy displayed by the getters-up of this institution, may know where to find a suitable *ready writer's* appeal to the feelings of the charitable. We will give a few extracts from it.

“Biblical records attest the prevalence of these diseases in the East, and with what severity they were inflicted as a divine punishment. If we have not, as in patriarchal times, men by word or touch stricken lepers from head to foot, have we not leprosy amongst us yet—however modified, still fearful enough to excite feelings of pity and abhorrence in the breasts of friends and strangers? If we do not observe many emulating the patience of Job, have we not hundreds around us similarly afflicted, covered with boils equally intolerable, and, in the carbuncular form, much more malignant?”

How comes it, the writer asks, that these cutaneous diseases are so common in Liverpool? He answers thus.

“There is no denying, at least disproving, the statement that more than one-half of them are more or less contagious. We have notes of not a few healthy-looking servants, who, when they came under observation, were leprosy on every covered part of the body; nurses, rosy-cheeked, and highly recommended, who, with the slightest possible irritation of the skin, had communicated to whole families a form of itch more common than agreeable—not to speak of similar interchanges of questionable civilities between servants themselves. We have had cases, again, wherein malignant ulceration had been traced to petty hucksters, with suppurative cancer of the face, whose hands, inadvertently smeared with the virus, had unfortunately served a customer with more than could be digested in sweetmeats and vegetables. And then what of baths, that were to have regenerated the species? Is it not notorious that the spread of skin-disease has kept pace with their multiplication? Leprous, syphilitic, and itch bathers following each other in rapid succession may produce a modification or diversification of the several complaints.

“Have we forgotten the memorable visitation of the Egyptian frigate *Scheah Gehald*, whose crew infected three attendants at the Paul Street Baths with typhus fever and malignant skin-disease, or in other words ‘the plague?’”

The author of this appeal then gives a telling sketch of what cancer can do on the human face divine, and winds up with a quotation from *A Treatise on Cancer*, which he published in 1858. In thus modestly alluding to his own literary labours, the writer adds a few words, which, by reason of their incomprehensible sublimity, will naturally strike awe into the minds of the public, to whom the Report is addressed, and doubtless obtain for the author veneration and respect.

As the old nurse says of the doctor in Molière, “What he says must be something wonderfully clever, *car je n’y comprends goutte!*”

“There is a law which operates towards the conjunction and blending of opposites in all things, by which the primal traits of the original forces become so fused or commingled as to preclude the development of each in its entirety and render a declension from the original type certain. This law holds good with regard to temperament in persons of opposite constitutional traits procreating a progeny assimilating one or other of the original types, and producing two varieties; viz., Hybrid Hæmasthenic and Hybrid Neurosthenic, classed according to their proximative affinities.”

Whether Mr. Smyth is or is not the author of the Report, and of this beautiful conceit, we leave others to tell; but, as he signs himself F.R.C.S., we will not suppose him capable of writing so much trash, and of addressing such a vulgar appeal to the benevolent, until he or some other assures us that his ink produced these things. Lord Stanley may be the President of the “Hospital”, but surely not the patron of a medical Report of this kind.

At present, it does not appear that the staff of the hospital is formed; the only medical officer being J. Seaton Smyth, F.R.C.S. But there is, we see, a physician who lends a helping hand as member of Committee—viz., Alexander R. Stookes, M.D., M.R.C.P.; and he, we take it, will naturally become physician to the future hospital; for every honorary surgeon requires an honorary consulting physician. We doctors always hunt best and most comfortably in couples.

We congratulate the people of Liverpool on their new institution, and have no doubt whatever that it will fully answer all the intentions and hopes of its very benevolent founder. We have so often pointed out in these pages the immense services rendered to suffering humanity, and the high exaltation of the profession which is obtained, by the gift of gratuitous medical services, that we need not again speak thereof here; neither need we hold up to universal commendation the self-sacrificing spirit, the pure and absolute benevolence, which preside over, or rather are the sources which stir up, medical men to give the gift. We will only, as in justice bound, record this last specimen of medical and surgical philanthropy; and request our brethren and the public, in this age of testimonials—of plate-service, silver teapots, and inkstands-giving—not to forget the labours of a gentleman who not only bestows his gratuitous medical labours upon every comer, but who also contributes £500—we mean “upwards of £500”—to the cause whereon his heart and hopes are evidently so warmly set. Let us, however, beg of him on another occasion not to allow the modesty of the writer to prevent him from fixing his signature to the Report. As the name of Dr. Stookes stands on the

Committee-list, and that of J. S. Smyth (or, as Mr. Sked calls him, Dr. Smyth) as honorary surgeon, and as either of these gentlemen might have written a "Medical Report" for the institution they are attached to, we know not to which of them the honour must be apportioned.

ANTHROPOLOGY AND ETHNOLOGY.

Dr. HUNT, the energetic President of the Anthropological Society, occupies many pages in his second anniversary address in discussing the meaning of the words anthropology and ethnology. Now, seeing that the great objects of the two existing Societies in London, the Anthropological and the Ethnological, are identical, with the exception that the former is also a publishing body, his remarks, on the face of them, will be looked upon by many as "much ado about nothing"—*vox et preterea nihil*. *Ἀνθρωπος* may be an older word than *ἔθνος*, as man necessarily claims priority to race; and consequently anthropology, or the science of man, may be said to take precedence of ethnology, or the science of the races of men. If, indeed, there be but one race, and not several and different races, in the great family of man, then it must be conceded that the title Anthropological is the appropriate one for a Society having for its object the science of man; but, on the other hand, if the races of man be many and different, then it is equally clear that Ethnological is the proper and befitting designation for a Society which has for its object, like the Ethnological Society of London, the science of the races of man.

Notwithstanding his remark, "that no two persons appear to be agreed as to what the word ethnology means," Dr. Hunt cannot be ignorant of the fact that there were established Societies, bearing the name of Ethnological Societies, in England, France, and America, long before the Anthropological Society of Paris was called into existence. The Ethnological Society of London had its origin from the Aborigines Protection Society, which was presided over by Sir Thomas Fowell Buxton, and was founded in 1843, to promote the study of ethnology. Dr. Hodgkin, a most zealous member of the Aborigines Protection Society, took an active part in its inauguration. Deputed by the Aborigines Protection Society, he also went to France, and there was instrumental in assisting his friend Dr. W. Edwards to establish the Société d'Ethnologie de Paris. This Society, however, during the Revolution of 1848, became defunct. On its resuscitation a few years ago, it took the modern title of Société d'Anthropologie de Paris.

Dr. Hunt was for some years the Honorary Secretary of the Ethnological Society of London, but became dissatisfied with the proceedings of the Council. In his dedicatory epistle to Dr. Paul Broca, Secr-

taire Général de la Société d'Anthropologie de Paris, etc., he says: "Finding myself unable to give my cordial support to a Society whose apparent objects were so utterly at variance with my own views—views in which I was not without supporters—the idea occurred to me of establishing in this country a really scientific Society, which, taking yours as a model, might become worthy of a great nation." Hence arose the Anthropological Society of London, with Dr. Hunt as its President. Whether such a Society was really wanted for the interest of science, we leave others to decide.

One fatal mistake, as he calls it, with which Dr. Hunt charges the Council of the Ethnological Society, is the admission of ladies to its evening meetings; but he forgets to mention the specified limitation of such attendance to those meetings in which there is nothing on the paper or subjects to be discussed which would be likely to offend the modesty or shock the delicacy of the female mind.

Notwithstanding the treatment which the Anthropological Society met with at the meeting of the British Association last year at Bath, Dr. Hunt still looks hopefully forward to the recognition of anthropology in a separate section in future years. Ladies, however, he must remember, have free admission to all the sections of the British Association; and no section has hitherto been more popular with the ladies than that of ethnology.

It must be confessed that the establishment of the Anthropological Society of London has given a fresh impetus to the study of ethnology. Competition is the order of the day. Both the parent Society and its offshoot appear to be flourishing. The Ethnological Society is in efficient activity, and has just issued another volume of its *Transactions*; and, whatever may be the opinion of Dr. Hunt as to the scientific value of the papers it contains, competent judges have not been slow to appreciate it.

We last week remarked that the late refusal of the Royal College of Physicians to take into consideration the condition of our army and navy medical brethren was a sign of its retrograde development. We were not aware, when we made the remark, that the proofs of the fact were so near at hand and so patent. This present College, which boasts of its liberal aspirations, its comprehensive tendencies, its desire to encircle in its arms the whole British medical family, and its tender regard for the interests of all branches of the profession, is, it turns out, after all, far less liberal than the old College of Paris. The old conservative College, in the close-borough days (as they were called), of Dr. Paris, had, we are proud to say, both courage and liberality enough to take an interest in, and actually to do a good work for, their army and navy medical brethren. We have great

pleasure in recording the fact that, on March 25th, 1850, it was proposed by the late Sir J. Forbes, and seconded by Dr. Wilson, that petitions be presented to both Houses of Parliament in favour of the claims of assistant-surgeons of the navy; and that the College thereupon appointed a Committee to draw the petition, and ordered the seals of the College to be affixed thereto. Still later, again, we find that on March 4th, 1857, a memorial was presented to the College, signed by a large number of army medical officers, containing an earnest request to the effect, that if the President and Censors, after full consideration, should think their position insufficient, they should express their conviction to the Secretary of War. It was, therefore, resolved by the Censors that letters be written, and they were written accordingly, to the Secretary of War (Lord Panmure) and the Director-General. All this, it will be observed, took place before the year of grace, and before the College entered upon its present career of liberal promises. This fact seems to illustrate well the old saying, that a Radical in power usually turns out a bigoted Tory. We might add to the above facts, that in 1855 the College received and referred to its Censors a petition from the medical students of England respecting grievances of the assistant navy surgeons; and moreover was actually not above receiving at the College a deputation from the students.

MR. RICHARD QUAIN has published *Observations on Medical Education*, being the introductory lecture delivered by him at the University College, London, for the session 1864-5. To the lecture he has made numerous additions, which are, in fact, suggestions to the Medical Council of Education. Mr. Quain, who has so long been a teacher, can scarcely fail to give valuable information on the subject of which he treats. Mr. Quain, amongst other things, expresses strongly the opinion that the "hospital resources of London are not, and, under the existing system, cannot be, used for the purposes of medical education, so as to bring out the largest attainable amount of good for the public and the profession." He considers that they are not properly organised for teaching—what should be the real end and aim of all medical education—the practical management of injuries and diseases. For teaching the elementary sciences, in which the first examination for degree or diploma are held, Mr. Quain would wish to see in London, not eleven schools—not a school at every hospital—but two or three schools established. At one of these schools, the student should be occupied until he has passed his first examination; and then he should proceed to the scene of practical instruction, the hospital. Mr. Quain also details the way in which pupils' studies should be directed there. We need hardly say, that we thoroughly go with this view of Mr. Quain. His opinions are the opinions

which have been on several occasions expressed by ourselves in these pages. It is out of the question to suppose that great teachers can be found in every one of the eleven schools of London; and absurd also to suppose that good teachers will continue to teach when not duly remunerated for their labours. We remember how we were some time ago taken to task for expressing these matter-of-fact opinions; and have, therefore, great pleasure in finding them supported by so high an authority as Mr. Quain.

"But it is unreasonable to expect that such men, that great teachers of physiology, anatomy, chemistry, etc., should be had in such number as the many schools in London and the provinces would require. It would be unreasonable to expect that such men should continue to cultivate and to teach those sciences, considering how ill remunerated their services are under the present system. The sciences are naturally, almost necessarily, soon given up for those pursuits which lead to practice and its emoluments. Men who might become great masters under favourable circumstances, embark in hospital and private practice. So they are lost to scientific investigation, and fail of the influence which is exercised by great teachers."

Mr. Quain concludes this part of his pamphlet with an appeal to medical officers of hospitals, asking them to come to some general agreement on the subject. Mr. Quain's lecture, with its many additions, is well worthy the attentive perusal of those engaged in education and its regulation. It will, however, we fear, be a very long age before the schools of London will be brought to do the rational act of amalgamation, so as to secure for the student first-rate teachers, and for teachers who would devote themselves to science the means of an honourable existence. Perhaps this question may some day occupy the attention of the Medical Council. So long as schools of medicine are established, not because students are in want of teachers, but because hospital physicians and surgeons are anxious to have students to lecture to—so long, we may be very sure, medical instruction will not be satisfactorily carried on. If Mr. Quain's proposal were carried out, we should then have a few first-rate schools for the instruction of the elementary sciences: we should have first-rate teachers; and we should then have, also, hospital physicians and surgeons engaged mainly in clinical instruction.

THE Royal Victoria Dispensary of Northampton is an institution whose working deserves the serious consideration of the profession. Its success proves the folly and the evil of the gratuitous medical services which are scattered broadcast over the country. This dispensary is no mushroom affair. It has just issued its twentieth Annual Report; and from it we learn the following telling facts. It is supported mainly by the working classes, but fostered by "those who believe the best way of helping the poor is by teaching them to help themselves." In 1844, only £23

were received from the patients. In 1864, "it is the pleasing duty of the Committee to state that the free members have contributed during the year no less a sum than £1,245; and that, after payment of all expenses of drugs and medical appliances, a sum of £918 has been divided among the three medical officers." We may add, as a remarkable fact, that the Governors, in their Report, thank the medical officers, and acknowledge their services and kindness to the patients in terms which are rarely seen in Reports of those institutions where gratuitous services are the order of the day.

THE Bourton and Cotswold Village Hospital has published its fourth Annual Report. It is in a flourishing condition. We have already, on several occasions, spoken of the great utility of these small hospitals; and wish them, therefore, every success. Our only regret is, that they should be tainted with the vice of gratuitous medical services. In the Report before us, we find that not only do the medical officers give their time and skill gratis, but that, up to the present time, they have "provided medicines gratuitously". Let it be remembered that no one has yet ventured to state in print, and defend, the reasons upon which gratuitous medical services are supposed to be founded.

M. REMAK, in the Berlin Medical Society, lately remarked that, many years ago, he attributed diphtheritic disease to an affection or injury of the sympathetic nerve. In diphtheritis, as already pointed out by Bretonneau, Maingault, and Trousseau, one of the first symptoms constantly observed is two peculiar swellings at the angle of the lower jaw, which are not connected with the lymphatic or salivary glands, but rather appear as an infiltration of the cellular tissue. M. Remak, therefore, concludes that the superior ganglion of the sympathetic is affected, and referred to a case where there were present, in a marked and apparently fatal degree, diphtheritic paralysis of the palate, the pharynx, the larynx, the extremities, and the muscles of the eye, and where he successfully operated by galvanism on the upper ganglion of the sympathetic.

Rokitansky, Skoda, Oppolzer, Fritsch, etc., have been summoned by the Government to deliberate concerning the St. Petersburg epidemic. They met; but, having (as the *Wien. Med. Woch.* of the 22nd instant says) no information on the subject, adjourned without reporting. The journal adds: "We have just received news from St. Petersburg, that the epidemic has assumed a dangerous character, and is spreading widely."

Reminiscences of Schönlein, by the pen of Virchow, are announced as shortly to appear from the Berlin press.

Great alterations, worthy of note have been lately made in the Paris Maternity Hospital. The lying-in wards have been so disposed as to be capable of being used alternately. Open fire-places have been adopted in place of former stoves. Each subdivision contains only six beds. When one division is in use, the adjoining one is left vacant and thoroughly ventilated. A circulation of air is also kept up between the beds. All the wards have been repainted in oil. The linen used is immediately removed from the neighbourhood of the wards. The water-closets are made after the English fashion. All direct communication between the infirmary and the lying-in wards is prevented. The physicians and students must visit these wards before those in the infirmary; and they cannot, after visiting the sick wards, again enter the lying-in wards until after some time has elapsed. Precautions as regards the making of autopsies have also been made.

The heads of the Vienna University are highly conservative—that is, have a strong taste of the paternal government under which they hold office. We lately referred to their determination of not holding the five-hundredth anniversary of the University on the proper day, because that day was unpleasant, on political grounds, to political authority. We now find that they have excluded the name of Virchow from the list of celebrities on whom they have decided to bestow the honorary title of Doctor. Virchow is a Berlin Liberal, and, besides this, offended the medical pride of the Viennese doctors by telling them, on one occasion, that they did not find the trichina because they did not know how to look for it.

During 1864, there were vaccinated, or revaccinated, 69,560 soldiers in the Prussian army. Of these, 59,396 had distinct, and 7,265 indistinct marks, and 2,899 no mark at all, of previous vaccination. The results of the vaccination were, 43,596 regular, 10,505 irregular pustules, and in 15,459 no pustules at all. Of the latter kind, on revaccination, 4,897 succeeded, and 10,392 were followed with no results. From this it appears that, in 69,560 men, the vaccination produced regular pustules in 48,493, or in about 70 per cent.

M. Dupin is the most rapid speaker in the French Assembly. He speaks at the rate of twenty-four lines of the *Moniteur* per minute; M. Thiers, at the rate of twenty-two lines; M. Rouher, of eighteen to twenty; and M. Jules Favre, of fifteen lines per minute.

On February 26th, twenty-five medical men assembled at the hospital at Brescia, invited by Dr. Rudolphi to witness anæsthesia produced by electricity. Of ninety-four patients operated on, six only manifested signs of its influence, and these were hysterical females.

THE CEREBRO-SPINAL MENINGITIS EPIDEMIC.

At the meeting of the Pathological Society of London on Tuesday last, Dr. SANDERSON, on behalf of Mr. Simon, who was unavoidably absent, exhibited the pathological results of two cases of the so-called epidemic cerebro-spinal meningitis which has recently prevailed in the neighbourhood of Dantzic.

One of the specimens was the spinal cord of a child, aged 3½ years, who died on the eighteenth day of the disease. The illness commenced in the usual way on March 26th, with flushing of the face, intense pain in the head and back of the neck, obstinate and repeated vomiting, which symptoms were soon followed by unconsciousness. Since the beginning of April, there had been strabismus. When first seen by Dr. Sanderson on April 11th, the patient was lying on her side, with the head retracted and the lower limbs drawn up. The general surface was pale, and the body much emaciated. The pulse and breathing were rapid, and the latter embarrassed. The pupils were insensible to light. The eyes, which were usually open and lustreless, squinted inwards. The patient gave no sign of consciousness when addressed by name; but when she was lifted in bed, pitiful cries of pain were uttered, the countenance became distorted, and it was observed that the head remained fixed in its original position of retraction. On the 12th, the breathing was more rapid and difficult, and the physical signs of hypostatic congestion were ascertained to exist; and on the following morning the child died.

The principal lesions discovered after death were the following. The pons Varolii was covered with a thick layer of concrete exudation, consisting entirely of pus-corpuscles, which extended forwards to the chiasma, backwards to the anterior surface of the medulla, and laterally to the inferior surface of the cerebellum and into the Sylvian fissures. The ventricles were distended with purulent fluid containing flakes of concrete pus. Under the arachnoid covering the convolutions on the convexities of both hemispheres, some of the intergyral spaces were occupied with similar concrete exudation. The posterior aspect of the spinal cord was covered with a layer of similar character, which extended from the cervical swelling to the cauda equina. The anterior surface of the cord was free from exudation. With the exception of collapse and excessive hyperæmia of the bases of both lungs, the other organs were healthy.

The particulars of the second case were not communicated in detail. It was stated that the patient, an adult male, aged 42, was admitted into hospital on the second day of the disease, and died on the tenth day. After the usual initial symptoms, rigor, vomiting, intense headache, and pain in the back of the neck, the patient became delirious, and subsequently passed into a state of stupor, from which he could be roused without difficulty. Dyspnoea came on about the seventh day, and gradually increased till death. In this case, as in the other, there was little pain, excepting when the patient was raised in bed. The head was constantly retracted; but there was no tetanic contraction of the muscles of the nape. The characteristic eruption of herpes labialis appeared on the seventh day.

The *post mortem* appearances, as regards the brain and spinal cord, resembled those already related, with the exception that here there was very little exudation on the base of the brain, but a considerable deposit on the pia mater covering the upper sur-

face of the cerebellum, from which point it extended forwards to the velum interpositum.

In answer to questions, Dr. SANDERSON stated that the facts observed at Dantzic afforded no ground for believing that the disease was communicable from person to person, or that it had anything in common with typhus fever, excepting in so far as each disease was no doubt dependent on a specific poison; that no eruptions resembling those of typhus or typhoid fever were observed; that impairment of the respiratory function was usually the immediate cause of death; and that, in general, the blood was found uncoagulated after death. In two cases, the spleen was excessively hyperæmic and soft as in typhus.

Dr. MURCHISON's attention had been devoted to the subject of epidemic cerebro-spinal meningitis long before the epidemic at Dantzic had been heard of. He thought that the appearances described by Dr. Sanderson left no doubt as to the existence of inflammation of the membranes of the brain and cord in the specimens which he had exhibited. But the important points to determine were, whether this inflammation was primary, or whether it was merely a local complication of some general abnormal condition; and, in the latter case, what was the real nature of the primary disease. Most pathologists admitted that there was such a disease as primary inflammation of the brain and cord independent of tubercle; but all practitioners knew full well that the disease was extremely rare; and that, when the lesions in question were found after death, they were most commonly due to some blood-disease. Dr. Murchison had found these lesions in cases of typhus fever, (see *Lancet*, April 22nd), scarlet fever, and pyæmia; and a gentleman was present who had found similar appearances in a large number of cases of yellow fever. When, therefore, we heard of so many as 1,200 persons dying of this affection in Dantzic and its neighbourhood within a few months, there could be no doubt that the lesions of the nervous centres were secondary to some general disease of the system. The question then was, What was this general disease? Was it, as had been stated, a disease which of necessity gave rise to inflammation of the cerebro-spinal membranes, and which had scarcely before been known in Britain? Dr. Murchison believed not.

The epidemic at Dantzic had been stated on good authority to be the same as the "epidemic cerebro-spinal meningitis" which had been described by many French and American writers, and which had been so common in America during the present war. Assuming this to be the case, we had ample materials for forming an opinion. Dr. Murchison had studied the accounts of these epidemics with great care, and had come to the conclusion that it was more than probable that most of them—he did not say all—were typhus fever complicated with meningitis, such as he had witnessed at the London Fever Hospital. This opinion, moreover, was the same as that held by some of the highest authorities on fever in America and France, such as Drs. Upham and Gaultier de Claubry. The signs of inflammation of the membranes of the brain were as marked in the American cases as at Dantzic; but this important observation had been made in America, that these signs were not always present, even in cases where their existence had been suspected from the previous symptoms. The other *post mortem* signs were those of typhus; viz., a fluid condition of the blood, enlargement and softening of the spleen, and hypostatic congestion of the lungs. Dr. Murchison would be glad to know what was the condition of the blood, the spleen, and the lungs, in the cases observed at Dantzic. A rash

had also been noted in a large number of the American cases, many of the descriptions of which corresponded in every particular with the eruption of typhus. (See *Lancet*, April 22nd, p. 418.) The etiology of the two diseases constituted another most important point of resemblance. Both in America and on the continent of Europe, the intimate relation between the occurrence of epidemic cerebro-spinal meningitis and overcrowding, with bad ventilation, had been a matter of general observation. If this remark did not apply to the Dantzic epidemic, then it differed not only from typhus, but from most epidemics of cerebro-spinal meningitis on record.

Dr. Murchison then proceeded to notice some objections which might be raised to his view of epidemic cerebro-spinal meningitis.

First, he had heard it said that the symptoms and whole course of the disease differed from those of typhus. After considerable experience in typhus fever, he could not assent to the soundness of this argument; and it must be borne in mind that typhus fever complicated with meningitis presented different symptoms from typhus not so complicated.

Secondly, it might be argued that inflammation of the cerebro-spinal membranes had been the rule at Dantzic and elsewhere, whereas in English typhus it was undoubtedly a rare exception. But it had been shown that in the so-called "epidemic cerebro-spinal meningitis" of America, cerebro-spinal meningitis was not always present, and with this fact before him, Dr. Murchison was not prepared to admit that six or eight autopsies, which were all that had been made out of 1200 fatal cases, were sufficient to decide the question in reference to the Dantzic epidemic. A more important fact remained to be stated. Outbreaks of undoubted typhus had been known to occur in England, in which almost every fatal case had been complicated with cerebral meningitis. About thirty years ago, a remarkable outbreak of this sort had occurred in an asylum for seamen in the East of London. The epidemic was described by the late Dr. Roupell, the author of an excellent work on typhus. Dr. Roupell's description of the rash and of the other symptoms made it clear that the fever was typhus. Many of the cases proved fatal, and they were dissected and recorded by an eminent pathologist, Mr. George Busk, who had assured Dr. Murchison that Dr. Roupell's description was perfectly correct, and that in almost every one of the cases lymph or pus was found on the surface of the brain.

Thirdly, it had been stated that there was no evidence of the disease at Dantzic being "personally communicable." Contradictory statements, however, had been made on this point, and it was worthy of consideration that many cases had proved fatal at Dantzic before the stage at which typhus probably becomes contagious. The communicability of typhus varied greatly according to circumstances. Dr. Christison and the late Dr. Alison had attended upwards of 280 cases of typhus in private houses, and in only one instance had the disease spread. Few medical men, however, would be induced by this fact to subscribe to the opinion of some persons, that typhus was not contagious. But after all, if the disease at Dantzic was not communicable, then it unquestionably differed from many of the epidemics of cerebro-spinal meningitis, already on record.

Lastly, it had been argued that typhus was unknown at Dantzic; but one of the most frightful epidemics of typhus ever known had occurred there, and it was a remarkable fact that the present epidemic had appeared almost simultaneously with an epidemic of typhus and relapsing fever in the adjacent country of Russia.

In conclusion, Dr. Murchison observed that, if he

had ventured to express his views in opposition to those of his friend Dr. Sanderson, he had done so solely with the hope that by free discussion light might be thrown on a disease, which still required elucidation.

Special Correspondence.

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

THE Medico-Chirurgical Society met on Wednesday, April 5th, in their Hall in George Street. After the exhibition of pathological specimens, Dr. J. B. Tuke, the recently elected Superintendent of the new Fife-shire Asylum, read a most interesting and valuable paper on Puerperal Insanity. The paper was based upon the statistics of 155 cases of the disease which have occurred during the last eighteen years in the Edinburgh Asylum. These cases having, at the time when they occurred, all been most accurately recorded in the asylum case-books, the deductions from them are of such a nature as to be fully relied on. Dr. Tuke remarked that the greatest confusion had been caused by the practice which had prevailed of classifying, under the one general term of puerperal insanity, all cases of insanity occurring during pregnancy, during the puerperal state, and during lactation. Differing greatly in its etiology, insanity occurring at these different periods manifests differences in form; and differences, it would appear, also exist in the results of treatment.

Dr. Tuke arranged his facts under the three heads of insanity of pregnancy, puerperal insanity, and insanity of lactation. During the period over which the statistics of Dr. Tuke extend, the proportion of cases of so-called puerperal insanity (using the word in its old and usually accepted sense) admitted into the asylum, was 7.1 per cent. of all female cases. Of the 155 cases, 28 were instances of the insanity of pregnancy, 73 were cases of true puerperal insanity, and 54 were cases of the insanity of lactation.

The most usual form of the insanity of pregnancy appears to be melancholia, mania occurring comparatively rarely. Of Dr. Tuke's 28 cases, 15 were instances of melancholia, only 2 of mania.

Moral insanity he pointed out to be not unfrequent during pregnancy, the most frequent form of it being dipsomania. Insanity appears to supervene much more frequently during the first than during any subsequent pregnancies. Of 28 cases of the insanity of pregnancy, 9 occurred during the first pregnancy. Insanity seems to occur at those periods of pregnancy which have generally been looked upon as most critical. Of 28 cases, 3 occurred during the third month, 5 during the fifth month, and 9 during the seventh month. Hereditary tendency exerts great influence on the production of the insanity of pregnancy; for, in 12 out of the 28 cases, hereditary predisposition was ascertained to exist.

The immense majority of patients affected with the insanity of pregnancy recover; of the 28 cases,

21 recovered. The results most to be feared are that the attack shall become chronic or pass into dementia.

Under the term puerperal insanity, Dr. Tuke included 73 cases; and in only two of these did the symptoms develop themselves at a later period than a month after labour. It appears, from his researches, that acute mania is undoubtedly the most frequent form of insanity observed at this period. Of 73 cases, 53 were acute mania, only 15 being cases of melancholia. First confinements appear to be most frequently complicated by puerperal insanity than by others; the tendency to the disease decreasing with every succeeding pregnancy. Of 73 cases, 31 occurred during the first confinement. Age exerts a powerful predisposing influence; there being a decided increase of liability after 30 years of age. Complicated labours powerfully predispose to it.

In 23 out of 73 cases, the labour was in some degree complicated.

Dr. Tuke pointed out that the results of treatment of this form of insanity were usually most satisfactory; the great proportion of cases being discharged cured within a period of six months after admission. The mania in these cases is usually very violent; but is not of long duration. When it lasts longer than four or six weeks, recovery is doubtful. After the acute mania has subsided, slight symptoms of dementia usually set in; these, however, soon pass off, and the patient appears as if waking from a long dream.

The number of cases of the insanity of lactation was 54; of which 39 recovered, 12 became demented, and 1 died; two remaining under treatment. The usual form of insanity is melancholia; 39 out of the 54 having been cases of this form of insanity. The patients were, as a rule, anæmic; many suffered from exophthalmia.

After the conclusion of Dr. Tuke's paper, Dr. Sanders shewed a most interesting case of a rare form of nervous disease to the Society. The subject of it is a man, about 35 years of age, who is affected with a remarkable disorder of the voluntary movements. When the patient is kept perfectly quiet, as during the night, nothing is noticeable. If caused to move, or in any way agitated, the most violent oscillating and somewhat rhythmical movements of nearly all the muscles of the body, with the exception of those of the face, take place. If the patient attempt to walk, these movements are so excessively violent that he nearly falls, and when he reaches a seat he can only with difficulty maintain himself in a sitting posture. Dr. Sanders pointed out that there was no paralysis of voluntary movements and no loss of muscular power; none of the sensory functions are in the slightest degree implicated. There is no tenderness over the spine; no affection of the heart.

The history of the patient is a curious one. Some months since, he fell from a height of twelve feet and sustained certain injuries, from which he recovered; no disorder of movements having made its appearance. A few days after returning to his work, he

again fell, and, although not injured, appeared to sustain a great fright. He immediately began to shake so violently that those who saw him thought him to be in a fit. These shaking movements have since continued.

In his very excellent and learned commentary on this case, Dr. Sanders maintained that the disorder was most probably only a functional one. He pointed out that the affection had no real resemblance to paralysis agitans, as might, at first sight, have been supposed. Besides there being no loss of muscular power in this case, there is a total absence of the scolytæ festinans, the bending forwards of the trunk, which, as Parkinson showed, is an essential feature in paralysis agitans. The case differed, Dr. Sanders likewise pointed out, from chorea, in the movements being rhythmical and not irregular, and in the muscles of expression being free from disordered movement. Although differing, to a certain extent, from chorea, the disease was one closely allied to it; and should be placed along with that class of nervous disorders which had been named by Galen and Sylvius *tremores*—a term which has been also used by Romberg, and serves as a link between the diseases which may be arranged under the terms paralysis and convulsions. Dr. Sanders suggested, that the disease affecting the patient which he had shewn to the Society might perhaps be conveniently named pseudo-paralysis agitans, or dystaxia agitans.

It is stated, that Dr. Pritchard's trial may possibly take place on Monday, May 8th. It is, however, doubtful whether the law-officers of the Crown will be able to get up the case by that date; if not, the trial will be postponed until the end of June or the beginning of July.

In a few days' time, Dr. Douglas MacLagan will commence his duties in the Royal Infirmary as Professor of Clinical Medicine.

NOTE ON TOBACCO SMOKING. Tobacco smoking is a process of *distillatio per decensum*, in which the vapours of the substance submitted to distillation, are not, as is usually the case, caused to descend by their own tension, but by the downward flow of a current of air, induced by the continuous production of a partial vacuum beneath the distilled body. The air which enters the mouth of a pipe issues from its stem after passing through a layer of ignited tobacco, carrying with it, among other things, watery vapour, carbonic acid, and nitrogen, together with the vapours of, or the products of the action of heat on, nicotine, a gummy matter, a resinous body, and a bitter principle. If the contents of a pipe be partially smoked and then examined, three distinct layers will be found. The first and uppermost consists of the ash of tobacco; the second consists of carbonised tobacco—that is to say, of tobacco which has been submitted to the action of heat sufficiently intense to cause its volatile parts to pass away, but not sufficiently intense to cause the oxidation of its carbon; the third layer consists of tobacco unacted upon. If a pipe is smoked by means of an aspirator, and the distillate examined, the smoke is found to be alkaline, and a quantity of water collects in the recipient, in which are suspended dark flakes of brown matter, and upon which an amber-coloured oil floats.

Association Intelligence.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting of this Branch will be held at the Rose Hotel, Canterbury, on Thursday, May 11th.

Notices of papers or cases to be communicated, should be sent immediately to the Honorary Secretary.

ROBERT L. BOWLES, L.R.C.P.,

Honorary Secretary.

Folkestone, April 24th, 1865.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE fourth meeting for the eighth session, 1864-65, was held at the Committee-room of the Union House, Dartford, on April 28th; FLAXMAN SPURRELL, Esq., in the chair. Twenty members and visitors were present.

Withdrawal of a Member. Albert Hind, Esq., of Gravesend, sent in his resignation.

New Member. Augustus Ward Allinson, Esq., of Woolwich, was elected a member, subject to the regulations of the Association respecting confirmation at the Branch annual meeting.

Communications. The following communications were read.

1. Case of Fibrous Disorganisation of the Pylorus. By John Grantham, Esq.

2. Case of Tracheotomy performed in Laryngitis. Laryngoscope employed in this case. Expulsion of a piece of mutton-bone by cough; presumed to have fallen into the larynx after the operation. By C. H. Allfrey, M.D.

3. Morbid Specimen of Cancer of the Prostate, from a subject in which there was Cancer of the Liver. In the spongy portion of the urethra there was cancerous deposit, superficial in position and slight in amount. By J. Cooper Forster, Esq.

4. Morbid Specimen of Epithelioma of the Cervix Uteri removed by the *Ecraseur* Seven Weeks after Parturition. By J. Braxton Hicks, M.D.

5. Demonstration of the Use of the Spiroscope. By A. Gardiner Brown, Esq.

6. Demonstration of the Use of the Laryngoscope. By C. H. Allfrey, M.D.

7. Demonstration of the Use of the Ophthalmoscope. By Chas. Bader, Esq.

Next Meeting. Adam Martin, M.D., was elected chairman of the meeting to be held at Rochester in September.

Dinner. The members and visitors adjourned to dinner at the Bull Hotel.

A PILFERER'S DEATH. An inquest has been held on the body of a labourer at Fenning's Wharf, who came by his death in a terrible manner. Daniel Crummings stated that deceased came to him and asked if a "drop" could be got out of some casks which they both supposed contained brandy or wine. They both had a "suck at the monkey," as it was called, and while the witness was somewhat burnt in the inside by what he took, the other man died in a few hours. Mr. Arkless, the Custom-house gauger, said the spirit in the cask sucked by deceased was pure Hamburg spirit 66·8 over proof, and was, in fact, "liquid fire." It was shown by the evidence of Mr. Lacey, a surgeon, that death was caused by the collapse.

Reports of Societies.

LIVERPOOL MEDICAL INSTITUTION.

APRIL 6TH, 1865.

JAMES HAKES, Esq., Vice-President, in the Chair.

Ovarian Disease. Dr. WILSON showed a specimen.

Foreign Body in the Female Bladder; Calculus. Dr. GRIMSDALE narrated the following case. A young lady, aged 15, full grown, and somewhat prematurely developed, commenced in July 1864 to complain of pain during micturition. She became hysterical, and was suspected to be guilty of masturbation. She would not, however, submit to a thorough examination until a fortnight ago, when Dr. Grimsdale was called to see her in consultation. She was placed under the influence of chloroform; and, on introducing a sound into the bladder, a foreign body was at once detected. There was a considerable tumefaction in the neighbourhood of the pubes, but rather to the left side; it was hard, and rather suggestive of being some growth connected with the symphysis. On the following evening, the patient being under the influence of chloroform, Dr. Grimsdale proceeded to operate. The urethra was rapidly dilated with Weiss's instrument, and the finger introduced into the bladder, when it immediately came upon a hair-pin abundantly covered with a phosphatic concretion. The pin was of an unusual length; and the point penetrated the coats of the bladder in a position corresponding to the tumefaction already noticed. The pin was then seized by a pair of forceps, and the concretion broken off it; but it was found quite impossible, by reason of its great length, to turn the pin in the bladder for the purpose of seizing its curved extremity; and it was consequently necessary to extract it point forwards through the urethra—a rather difficult proceeding. On the second day after the operation, the patient was able to pass water voluntarily, and she soon made a complete recovery. On measuring the hair-pin, each prong was found to be exactly four inches long. The indurated spot felt near the symphysis was doubtless caused by inflammatory action; an effort of nature to expel the foreign body through the parietal walls. All this entirely subsided in a few days. Dr. Grimsdale concluded his remarks by advocating rapid dilatation of the urethra in the treatment of these cases.

Dr. Balman, Dr. Nottingham, the President, Mr. Steele, and Dr. Telford, took part in the discussion.

VACCINOGENOUS COWS. Dr. Warlomont of Brussels is forming an establishment for keeping cows to supply vaccine matter; or, as they are called, vaccinogenous cows.

INCREASE OF NATIONS. Official returns lately issued show the rate at which various countries increase and multiply. In Great Britain in the year 1862 a living child was born to every 28 persons. In France (1861), only one child to every 37 persons; Austria (1862), one to every 42; Prussia (1860), one to every 25; Belgium (1861), one to every 32; Sweden (1859), one to every 29; Denmark and the Duchies (1862), one to every 31; Bavaria (1861), one to every 29; Hanover (1861), one to every 31; Spain and Balearic Islands (1861), one to every 25; Greece (1860), one to every 35; Chili (1862), one to every 24.

Correspondence.

MEDICAL ETIQUETTE.

LETTER FROM WILLIAM THELWALL, Esq.

SIR,—Will you oblige me by publishing the following in your JOURNAL? I am, etc.,

W. THELWALL.

Farndon, Cheshire, April 3, 1865.

I was called on Monday, March 13th, to visit a gentleman who was thrown from his horse. On the following day, a consultation being desired, I wrote to Dr. McEwen and Dr. Dobie; but, both being from home, the messenger brought Dr. Waters, who arrived about 5 P.M. Dr. Waters wished to see the patient again the same evening, and came about 11 P.M., bringing with him another practitioner, Mr. John Harrison. I need not say how astonished I was, as no one ever asked Dr. Waters to bring any one with him. The brother of the patient remarked to me at the time the intrusion of a stranger, and seemed much annoyed. After examining into the case, they went to the other side of the room and conversed together *sotto voce*. They came the following day, and, indeed, continued their attendance until the death of the poor fellow on the Friday following.

The same evening (Friday), Dr. Waters wrote a letter to me, wishing to obtain a *post mortem* examination. Mr. Eden, a retired practitioner and friend of the family, who had remained at the inn during the week that Mr. — was ill, forwarded the letter of Dr. Waters; and he (Mr. Eden), who remained in Chester all day on Saturday, received a telegram that the friends were agreeable.

Dr. Waters and Mr. John Harrison, forthwith proceeded to Churton, where the body lay; and, at 5 P.M., made a *post mortem* examination, without in any way communicating with me, which they could easily have done in twenty minutes.

About 10 P.M. the same evening, Mr. Eden came to my house, and informed my son that a *post mortem* examination had been made. This was the first intimation I had of the matter.

Mr. Churton, the coroner, had informed Mr. Eden that an inquest would be held; but, in spite of this, the examination was made.

I subsequently received a note from Dr. Waters, from which I extract the following remarks.

“Nicholas Street, Chester, March 23rd, 1865.

“Dear Sir,—I find that I and Mr. Harrison got into trouble with the coroner and annoyed you by the *post mortem* examination of our poor patient. I was not aware that I was doing any wrong towards the coroner; and as I would not willingly be guilty of any discourtesy towards you, I write this note to explain how it happened that the *post mortem* examination was so suddenly performed. I wrote to you, intimating my wish that it should be permitted, feeling assured of the existence of more internal mischief than met the eye or was apparent on the surface.

“As for the *post mortem* examination being performed in your absence, I wrote to you as the proper person to move in the matter. The following morning (Saturday), Mr. Eden called on me, and said that he had no doubt the request would be granted; that my letter had been sent to the father; and that they expected a telegram conveying assent. I then asked when it might be done; he replied, that the mother would object to it on Sunday. I then proposed 5 P.M. for leaving Chester, and that was arranged; for we

assumed that the consent would be given. I left all arrangements respecting you to Mr. Eden, on the supposition that you and he must have spoken together on the subject.

“On arriving at Churton, you were not there. My impression was, that you did not care to be present. Mr. Harrison and I decided on Saturday as being free to go. I am very sorry if you think I have been in any way wanting in courtesy to you. I should be truly sorry to be guilty of it.

“The *post mortem* examination was suddenly decided on in Chester. It appears that there was no way of communicating with you; for, until Mr. Eden mentioned it, I did not suppose you were waiting to be summoned. Had any of us thought so, we should not have neglected it.

“Believe me, yours truly,

“EDWARD WATERS.”

THE COLLEGE OF PHYSICIANS.

SIR,—The time has long gone by when the Fellows of the Royal College of Physicians thought that, by separating themselves from the great body of practitioners of this country, they enhanced their own status. The fact of the College having appointed a Committee to investigate the alleged grievances of their brethren in the army and navy is a sufficient proof that they consider that they have common interests with that large body of excellent, deserving, and, I regret to say, ill-used body. Carefully as that Committee has investigated the charges brought against high authorities, we have full assurance that the general rumours and allegations have not been exaggerated, and that the College has not been engaged in seeking out a mare's nest. There may possibly be among us dissentients as to the exact method to be pursued in redressing the grievances complained of; but I apprehend there can be none as to the justice of the cause we are engaged in, and the propriety of this ancient corporation seeking to ameliorate the condition of those to whom the health and strength of the British army are mainly entrusted.

The greatness of our College is secured from the moment that the entire medical profession are made to feel that the same pulse beats in all, and that an injury done to one of its members is reflected by the vigorous action at once called forth in this ancient corporation.

This, sir, is not a mere abstract question of right and wrong, which can be disposed of by an argument of debaters; it is not one merely of professional etiquette and sensitiveness. I place it on the still broader ground of national importance; and I call upon the Fellows of the College to make it their own personal question, because they are Englishmen, as well as medical men.

Far be it from me to underrate any portion of the material of which the British army is composed; but the higher my estimate of all its constituents is, the higher necessarily becomes that of the medical department, upon which, above all others, the efficiency depends. I will not weary you with statistical details as to the former and present mortality of the two services; but I may remind you of the great fact that, owing to the sanitary improvements which our professional brethren have introduced, the mortality in the army has been reduced during the last few years from an average much above that of the general population to a level with the healthier rates prevailing in the latter. If, then, so much depends, for the daily comfort and the fighting efficiency of our troops, upon the due surveillance of the medical

officer, what justification can be offered for the habitual and contemptuous disregard of his feelings of which he has so long and justly complained? The curriculum through which the military surgeon passes is as expensive as that of the average combatant officers; his intellectual calibre is equal, at all events; and his devotion to his high calling is unquestioned. And I maintain that the estimation which the medical officers generally enjoy among their messmates is not in any way calculated to justify the snubbing which dukes and lords in authority are wont to give them. Who is the man that, in the intimate relations of every-day regimental life, is the most generally popular and beloved, but the medical man? It is, indeed, surprising that the Horse Guards have not more completely debarred men from taking medical appointments; and it shows that social influences and social qualities have even more power than "general orders" and "minutes".

But, for the sake of argument, let me admit that the medical officers of the army are socially inferior to the other officers. What follows? It appears to me that it renders action on the part of the medical corporations all the more imperative, in order to secure the entrance of a class of men who shall be able in every way to occupy a better social position. Mind, I do not admit the implied inferiority, except in certain well known cases which the Director-General has himself created. But, if it exist, it reacts injuriously upon every one of us; and it is this aspect which I would implore those Fellows to ponder upon who think the medical officers of the army a section of the profession with whom we have no concern. If the army surgeon be of an inferior mould, the estimate in which he is held by his brother officers will influence the estimate in which we are held by the aristocratic families from which some of the combatant officers are drawn. It operates injuriously upon our social relations, and upon our power for good as professional men. We may not generally perceive this in private life, because not brought up with the feelings of the paramount importance of military rank and precedence, or rather because, belonging to that large body of the public in which seniority and talent are the only patents of precedence, we determine our social status in a different way. But there are few among us who may not have had occasional opportunities of receiving the cold shoulder where the "doctor" alone was in consideration. I am confident that, throughout the upper classes of society, a secret misgiving haunts the majority of its members that the title of Doctor rather diminishes than increases a man's claims to consideration. I do not mention this except as an argument in favour of our doing all we can to raise the social status of the army and navy medical officers.

Let us now for an instant consider how important to the individual medical officer the "apparent trifles" are which form many of the subjects of complaint. Reflect that his intercourse is confined to men whose whole life is more or less under the control of artificial distinctions of rank. He cannot, if he would, emancipate himself from all those petty annoyances which a want of due respect in the hundred occurrences of daily life may cause him. If we meet with derogatory treatment in a patient's house, which scarcely ever happens, we have our own remedy. The army medical officer is isolated, though living with messmates, unless they show him the regard due to his rank, and unless he feels that he is able, if necessary, to enforce it. The army medical officer's happiness is bound up with the exact place assigned to him at mess, at courts of inquiry, at all public and festive occasions. He pays all the dues of his nominal rank, and he receives but a portion of the corre-

sponding advantages; and though often the recipient of the Victoria Cross, and though he saves the life of thousands by good advice, and of his commander-in-chief by the edge of his good sword; though it lies with him to render the army efficient or inefficient, according as he places the camp, or the barrack, or hospital, or attends to the quality of the food and what not; although he is expected to do, and does, all this, still forsooth he is not to be treated with the common justice which every Englishman can claim. He is promised one thing, and receives, as fulfilment of a promise upon which he has staked a life's venture, reduced pay and allowances, diminished honour, diminished hope and self-esteem. Let us not be parties to such a system. *Sed contra*—I say to every Fellow of our College—*sed contra fortior ito!*

I am, etc., A FELLOW.

May 1865.

THE BROMIDES IN EPILEPSY.

LETTER FROM T. HILLIER, M.D.

SIR,—As, in the last two numbers of your JOURNAL, reference has been made to the employment of bromide of potassium for epilepsy, it will probably interest some of your readers if I give a short sketch of two cases recently under my care in the Hospital for Sick Children.

CASE I. A. B., aged 5 years, had had fits since October 1863. At first they lasted less than half a minute, and appeared to consist simply in a feeling of giddiness. Latterly they had increased much in frequency and length, lasting two or three minutes. They were attended with unconsciousness and loss of power; so that the patient would fall, if in a standing posture. There was some rigidity of the limbs during an attack; no lividity, and no foaming. The fits occurred eight or ten times in every twenty-four hours. She was slightly drowsy after the fits, three of which often occurred in rapid succession. Her head was usually drawn to the left in the fits. She was admitted to the hospital on June 4th, 1864. She had during the next five days from eight to fourteen attacks each day. I then gave her five grains of bromide of potassium in water every two hours night and day—i. e., a drachm in twenty-four hours. There was no marked result until June 16th, the fits occurring, on the average, to the number of eighteen in twenty-four hours. I then increased the dose of bromide from five to seven grains every two hours. On the 17th, she had nineteen fits; on the 18th, thirteen; on the 19th, only seven; on the 20th, two; for three following days, one daily; on the 24th, two; on the 25th, one; and after this none. The bromide had no bad effect upon her. She soon after this had a mild attack of measles, but no fits. I heard of her in January last. She was without an attack until Christmas-day, when, after eating a great deal of plum-pudding, mince-pies, etc., she had one severe attack.

CASE II. M. A. M., aged 6 years, had had fits for three years and a half. They had latterly become extremely frequent, sometimes twelve in an hour. The fits now seen began with rigidity, and ended by convulsive movements. She was unconscious throughout. When admitted, she could not raise herself in bed; nor sit up when raised, her head falling backwards or forwards. The left arm was almost absolutely paralysed. She could not raise either of her legs from the bed, nor stand. On December 22nd, I gave her ten grains of bromide of ammonium in water every two hours, or two drachms in twenty-four hours. On the 23rd, she had twenty-nine fits; on the 24th, she had sixteen fits; on the 25th, five

fits; after which *she did not have another*. On Jan. 2nd, she was ordered to take the bromide every six hours only, and one drachm of cod-liver oil three times a day. On January 6th, the bromide was omitted. From this time she steadily improved; could sit up and stand on January 16th; could walk on the 25th; and on February 8th appeared quite well. Her intellect, which had been very dull, was much improved. She was then discharged, and I have not heard of her since.

There can be little or no doubt, in those cases, that very great benefit was derived from *very large doses* of bromide of potassium in one, and of bromide of ammonium in the other. The doses were larger than were given by M. Moreau in adults. I am satisfied that this drug does not suit all cases of epilepsy; but that it has a remarkably beneficial effect in others there can be no question. It will be a point for future observation to determine to what special cases it is suited. If any of your readers have cases similar to those which I have sketched under their care, I hope they will give a trial to large doses of one of the bromides.

I am, etc.,

THOMAS HILLIER, M.D.,

Physician to the Hospital for Sick Children.

32, Queen Anne Street, Cavendish Square, May 1st, 1865.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on April 26th.

Adams, Josiah Oake, Plymouth
Brigstocke, Charles Arthur, Carmarthen
Bywater, Thomas Edward Gagg, Knottingley
Clothier, Henry, Haslemere
Gray, John Henry, Poplar
Grose, Francis John, Bengal
Howard, Frederick Robertson, Halesworth
Hyland, James Kieran, Dublin
Langley, John Thomas, Monmouth
Leake, Jonas Richard, Upper Norwood
Peacock, James Bailey, Leeds
Phillips, Edward England, Bath
Rix, Richard Avery, Beccles, Suffolk
Rogers, Henry Cripps, Newport Pagnell
Rundle, Henry, Plymouth
Spencer, George Outhwaite, Notting Hill
Spooner, Edward Monro, Blandford
Wells, James, Nailsworth
Westmorland, Joseph, Leeds
Wiles, William, Wootton-under-Edge
Williams, Richard Morgan, Merthyr Tydvil
Wright, John Harrington, Woolwich

At the same meeting of the Court—

Broster, Edward Brereton, H.M. Dockyard, Woolwich
Bickford, Thomas Leamant, H.M.S. *Fisgard*, Woolwich, passed their examinations for Naval Surgeons. These gentlemen had previously been admitted members of the College: their diplomas bearing date respectively June 15th, 1855, and March 19th, 1858.

Admitted on April 27th—

Allen, Bryan Holme, London
Beck, Robert Croft, Louth, Lincolnshire
Cole, Edward Francis Jenkins, St. Helena
Cullingworth, Charles James, Leeds
Garnsey, Edwin Charles, Wells, Somerset
Griffiths, Richard Samuel Purnell, Cheltenham
Hackney, John, Myddelton Square
Hampshire, Frederick Knowlton, Kensington
Jones, William Griffith, Llanelly, Carmarthen
Knott, Sydneyham John, Jamaica
Lamb, George, Hull
Lucas, Herbert, Hitchin, Herts
Nunneley, Frederick Barham, Burton-on-Trent
Place, Thomas Lloyd, Wickham Market
Rendle, George, Newington Causeway
Thompson, Joseph, Nottingham
Thurgar, Benjamin Bingay, Torquay, Devon
Tidswell, Thomas Harrison, Spalding
Treves, William Knight, Dorchester
Webb, John Holden, Tunbridge Wells

APOTHECARIES' HALL. On April 27th, 1865, the following Licentiates were admitted:—

Dick, Thomas, Harrington, Cumberland
Fernie, James, Kimbolton, Huntingdonshire
Haydon, Nathaniel Thomas John, Bovey Tracey, Devonshire
Hoffmeister, William, Cowes, Isle of Wight
Hyatt, Brownlow North, Doughty Street, Mecklenburgh Square
At the same Court, the following passed the first examination:—

Arundell, Shirley Woolmer, General Hospital, Birmingham

APPOINTMENTS.

ANNANDALE, Thomas, Esq., elected Assistant-Surgeon to the Royal Infirmary, Edinburgh.
*BILLING, Archibald, M.D., F.R.S., elected Consulting Physician to the Dispensary for Diseases of the Throat.
*FRASER, Patrick, M.D., elected Physician to the Dispensary for Diseases of the Throat.

BIRTH.

AUBIN. On April 26th, at Kingswinford, South Staffordshire, the wife of *Thomas J. Aubin, M.D., of a son.

MARRIAGE.

ELLISTON—POTTER. On April 27th, at the Parish Church, Dartford, *W. A. Elliston, M.D., second son of the late Wm. Elliston, Esq., Surgeon, of Ipswich, to Janet, youngest daughter of R. E. Potter, Esq., of Dartford, Kent.

DEATHS.

KENNY, Mason S., M.D., late of Halifax, at Ballinrobe, aged 77, on April 25.
SAWYER, John J., Esq., Surgeon, of Park Street, Grosvenor Square, on April 14.

DINNER TO SIR JOSEPH OLIFFE. On Saturday last, a dinner was given in Paris to Sir Joseph Oliffe. Lord Gray presided; and Lord Cowley, the Hon. W. Grey, the Hon. Spencer Cowper, Mr. Falconer Atlee, and others, were present.

PRESERVATION OF LEMONADE. The spontaneous change which this liquid undergoes prevents its being kept longer than a few days. It is suggested by M. Ladi to employ the sulphite of magnesia as a means of preserving it for a longer time; the gradual oxydation by which it becomes converted into the sulphate of magnesia appearing to prevent the alteration. A small quantity only is said to be sufficient. (*Amer. Jour. Pharm.*)

HOSPITAL FOR WOMEN. Her Royal Highness the Princess of Wales has graciously signified her pleasure to become the patron of the Hospital for Women, Soho Square, and has given a donation in aid of the proposed new wing. The rate of mortality of medical cases was 7 per cent.; viz., of males, 9.5 per cent.; of females, 2.4 per cent. The rate of mortality of surgical cases was 6.3 per cent.; viz., of males, 6.4 per cent.; of females, 6 per cent.

BELFAST. The sanitary condition of Belfast is not so bad as that of Cork, but it is far from being satisfactory. At a meeting of the Building and Hospital Committee of the Union, Dr. Reid thought that the epidemic raging in Russia was the same as they often had in Belfast—spotted fever, typhus, and relapsing fever. Consequently, he did not think it necessary to alter their arrangements. Mr. Tierney thought the epidemic might be attributed to the bad food people got in Lent. The epidemic was a humbug. What the poor wanted was a good supply of water. The streets were in a disgraceful state, with pools of water lying before the doors. Dr. Mapother had given the mortality per 1,000 in six places in Ireland, and Belfast stood pre-eminent for the greatest mortality—the rate being 28.9, while in Dublin it was only 24.6.

THE HÔTEL-DIEU. In 1313, under Philippe le Bel, the deaths in the Hôtel-Dieu amounted to eighty a day; and not very long since four and even six patients were placed in one bed in that hospital. The new hospital will cover 22,000 yards. It will contain 716 beds in eighteen halls, containing six beds each; nineteen, containing six beds each; three, from ten to twelve beds; and eighty-four rooms, containing from one to two beds, all supplied with 100 cubic metres of fresh air by the hour for each bed.

UNIVERSITY OF LONDON. The Senate, at a meeting held on April 26th, elected the following gentlemen as Examiners for the ensuing year, commencing on the 1st of July next. *Chemistry*: Henry Debus, Ph.D., F.R.S.; and Professor A. W. Williamson, Ph.D., F.R.S. *Botany and Vegetable Physiology*: Rev. M. J. Berkeley, M.A.; and Thomas Thomson, M.D., F.R.S. *Practice of Medicine*: Professor Edmund A. Parkes, M.D., F.R.S.; and Francis Sibson, M.D., F.R.S. *Surgery*: Professor John E. Erichsen; and John Hilton, Esq., F.R.S. *Anatomy*: Professor Geo. V. Ellis; and Professor Peter Redfern, M.D. *Physiology, Comparative Anatomy, and Zoology*: Professor Thomas H. Huxley, Ph.D., F.R.S.; and William S. Savory, M.B., F.R.S. *Midwifery*: John B. Hicks, M.D., F.R.S.; and William O. Priestley, M.D. *Materia Medica and Pharmaceutical Chemistry*: Frederick J. Farre, M.D.; and Samuel O. Habershon, M.D. *Forensic Medicine*: Professor William A. Guy, M.B.; and William Odling, M.B., F.R.S.

THE GARRISON HOSPITAL AT CHATHAM. The range of buildings hitherto used as a garrison hospital for the troops of the line at Chatham being no longer required for that purpose, in consequence of the hospital at Fort Pitt being sufficiently large for the entire garrison, orders were some time since received from the War Office directing the conversion of the garrison hospital into quarters for the troops of the infantry regiments at that station. The building so appropriated has been completed, and handed over to the officials connected with the barrack departments. The hospital will provide accommodation for 350 men, twelve in each room. All the separate barrack-rooms into which the building has been divided are light, lofty, and exceedingly well ventilated both by day and night. Each room is lighted with gas, and there is an abundant supply of water for the troops to whom the quarters are appropriated. The buildings have been inspected, prior to the troops taking possession of them, by Major-General Sir Robert Walpole, K.C.B., and the other officers of the staff of the garrison.

THE SCOTCH LAW OF LUNACY. At Aberdeen lately, an old man was found guilty of murder. He pleaded guilty twice over; but the case was proved, nevertheless, as if he had not pleaded at all. The defence set up was insanity; and it did appear that the prisoner had fallen into ill health and become subject to epileptic fits, and entertained delusions as to his property. The Lord Justice Clerk told the jury that a delusion did not relieve him from criminal responsibility, unless the act of murder could be traced to this delusion. The result of it would be to make most inmates of lunatic asylums criminally responsible. The Lord Justice Clerk also distinguished between bodily and mental disease; but where the one begins and the other ends he did not say, and no man knoweth. The jury seem to have been satisfied with his distinction; for nine of the fifteen thought there was not sufficient evidence of insanity, though there could be no doubt of disease involving the brain. They did not even recommend him to mercy. His only chance of escape now lies with the Lord Justice Clerk.

BRITON MEDICAL AND GENERAL LIFE ASSOCIATION. At the general meeting of shareholders and members of this Association, held March 30th, it was stated in the Report for the year ending December 31st, 1864, that the proposals for new assurances had been 3,260 in number, and the amount proposed £318,888. Of these, 2,454 had been completed, and that number of policies issued, assuring £621,885, and producing in new annual premiums the sum of £20,060:14:3. The gross income of the Association had increased to £124,091:7:4; and, after the payment of all outgoings, the balance of income over expenditure for the year was £30,560:10:10. The assets of the Association amounted to £247,503:8:3. The Association has suffered somewhat heavily from the highly increased mortality in the past year. The claims had been two hundred in number, and amounted to £60,810:8:6. Mr. Francis Webb, Dr. W. Tyler Smith, and Mr. Thomas B. Jones, were re-elected Directors. Dr. E. H. Sieveking was elected a Director, in the room of William Manton, Esq., deceased. A dividend, at the rate of six per cent. per annum on the paid up capital of the Company as increased by the bonus, was declared. Thanks were passed to the Directors, to the Medical Officers and Solicitors, to the Consulting Actuary, to the Actuary and Secretary of the Association, to the Provincial Superintendent, to the District Managers and Agents, and to the Chairman; with which the proceedings terminated.

NEW YORK INFIRMARY FOR WOMEN AND CHILDREN. The New York Infirmary for Women and Children has long been under the professional care of Drs. Elizabeth and Emily Blackwell. Drs. Valentine Mott and Willard Parker are the consulting surgeons of the infirmary. The report for 1864, just issued, shows that during the last year 5,437 persons were relieved. The last legislature of New York enlarged the charter of the infirmary so as to confer collegiate powers upon it; and an effort is being made to endow a Woman's Medical College in connexion with it. The effort to introduce women into the medical profession has not thus far been very successful, and leads to grave doubts whether there is a real demand for them; but, if we are to have women practitioners of medicine, it is certainly very desirable that they should be properly educated. Most of the attempts to educate women in this direction have been in connexion with hybrid schools, where everything but legitimate medicine is taught. We are not, however, we confess, of those who think that the medical profession is exactly a legitimate sphere for woman's usefulness. (*Phil. Med. Press.*)

A POOR-LAW MEDICAL OFFICER'S DUTY. Dr. Stalard in a pamphlet on Workhouse Hospitals, speaks thus of the duties of the Poor-law medical officer:—"In the first place, he is required to be a fully qualified practitioner. The position of union surgeon is rather damaging than otherwise to the holder's reputation. Neither the Poor-law commissioners, nor the guardians generally, encourage the practice of surgery, or the admission of acute cases into the workhouse hospital. A proper staff of nurses, etc., would in that case be absolutely necessary. Any professional zeal manifested by the surgeon is too often checked by remonstrance as to the expense incurred. The duties of the workhouse surgeon ought to be commenced before two o'clock in the day, that he may inspect the applicants for admission, who have to be washed, clothed, and accommodated before night. It is his first duty to see that no contagious disease enters the house. Every person not vaccinated must have that operation at once performed. The next visit is to the surgery; and notice of his

arrival having been given, he examines every inmate who expresses a wish to consult him. Amongst these there will be a large proportion of malingerers; others solicit change of diet, abstinence from work, extra beer, and other indulgences which the medical officer can alone grant. Then come the children from the schools, all of whom require constant supervision. The casual ward, the lying-in ward, the insane ward, and the nursery, have all to receive a visit; and, last of all, the hospital.

EXTRACT OF FLESH. Liebig speaks in very high terms of his *Extractum Carnis* in the *Annalen der Chemie und Pharmacie*. Since the introduction of this extract of meat into the Bavarian *Pharmacopœia*, its great efficacy has been practically confirmed. In the court-pharmacy here nearly 5000 pounds weight of beef are annually employed for this object. In hospitals, the physician will, by means of the extract of meat, be enabled to give his patients a soup quite free from fat and of any strength he may desire. A pound of extract of meat is sufficient, when boiled with slices of bread, potatoes, and some salt, to afford a meat soup for 128 soldiers, such as is not to be had of equal strength in the best hotels. The employment of the extract of meat would be of the highest importance to travellers. The introduction into Europe of the extract of meat at half or a third of its present price from countries where meat is of scarcely any value, would be a true blessing to the European population. In 1862, I had a visit from Herr Giebert, of Hamburg, an engineer, who has spent many years in South America, and among other places in Uruguay, where hundreds of thousands of sheep and oxen are killed solely on account of their skins and fat. Having seen my chemical letters, in which the extract of meat is described, he travelled to Munich, to learn the mode of its manufacture. I introduced him to the manager, Prof. Pettenkofer, who made him acquainted with the minutest details of the process. Herr Giebert returned in 1863 to Uruguay, but it was nearly a year before he could, with the apparatus made in Berlin, overcome the many difficulties which attended the arrangement and introduction of a new branch of industry, and commence the manufacture. A letter received from him a month ago, informed me that the first produce of his manufacture of extract of meat had been sent off to Europe. The first sample of about eighty pounds of extract of beef and thirty of mutton, arrived in Munich some days ago, and we have the great satisfaction to be able to say that its quality is excellent, as was to be expected from the flesh of half wild sheep and oxen. The price is a third of the present price in Europe. A number of facts testify to the unchangeability of the extract of meat under the most unfavourable circumstances in damp unoccupied cellars, and in moist warm air; if the product is pure, it is not at all inclined to mould, and I have specimens before me from the court-pharmacy and from Principal Friedel (of the Sanitary Society), which were kept from eight to fifteen years, closed with a loose cork and paper, and on which not a trace of injurious change is perceptible. (*Dublin Med. Press.*)

SUICIDE BY BATTLE'S VERMIN KILLER. One evening lately a middle-aged lady alighted at the Dawlish Station and proceeded to the hotel where she represented that she came from America. She retired to rest, and on the following day was found dead in her bed, apparently having poisoned herself with Battle's Vermin Killer, packet labels of which were found by her bedside. It has since transpired that the deceased was the wife of a stationer at Devonport. Her husband said she left home in good spirits. His eldest child told him of her leaving, but

he did not think much about it. She had shown symptoms of mental derangement. She had a spinal complaint and suffered severely from pains in the head. At times she had paroxysms. Four years ago she attempted to drown herself in a tank. She underwent an operation at New York, when the operator told him she would probably put an end to her life. She often had dizziness in the head. The coroner said it was very desirable that an Act of Parliament should be passed making it more difficult than at present to get poisons. Several paper wrappers of Battle's and Simpson's vermin killer found in the room were produced. Dr. Baker of Dawlish was called in to see the deceased when she had been dead two or three hours. She was lying on her back, the head thrown backwards, the arms drawn up towards the head, and the fingers drawn forcibly towards the palms of the hands. There was apparently great palor and extreme rigidity of the whole body. The face was thin and pallid, especially the gums and mouth. Between the teeth, which were partially closed, was an almond in two pieces. The eyes were closed but the pupils were extremely dilated. The spine of the body was completely curved. On two pocket-handkerchiefs of the deceased's were distinct traces of a blue powder. On his way home he purchased a packet of Battle's vermin powder and found it to contain about forty grains of a bluish powder which contained about four grains of strychnine, which was quite sufficient to cause death. The packet was properly labelled. The late Mrs. Vyse of Ludgate Hill, poisoned her children with the same kind of powder, which on being analysed was found to consist of starch, Prussian blue, and strychnine. As Dr. Baker could not state positively that poison was the cause of death, it was decided to adjourn the inquest. At the adjourned inquest Mr. Coroner Cuming stated that he had ordered a *post mortem* examination. Dr. Baker had sent the contents of the stomach to Dr. Herapath, of Bristol, for analysis. The coroner had not given any instructions for this to be done, and now objected to the county being put to the expense. He said there could be no doubt that the case was one of suicide, therefore an analysis was unnecessary. Dr. Baker said that the coroner had left the case with him, and he was not prepared to state the cause of death unless the evidence of Dr. Herapath was taken. The coroner replied that he would not let medical gentlemen act as Dr. Baker had done without the coroner's instructions. Dr. Baker then gave the result of his examination. He found no marks of violence nor anything except poison to account for death. Dr. Herapath said he would forego his usual fee. He then stated that death had been caused by arsenic. Dr. Herapath adds: That the deceased had three or four parcels of rat poison in her reticule or about the room, some of which were empty, others in reserve. Two papers of Simpson's vermin killer had been disposed of and one parcel of Battle's had apparently been used, "some blue stains being found in the mouth and at the angles of the jaw, whilst the pocket-handkerchief was marked with blue stains also." The rigidity and contortions of the dead body led Dr. Baker to infer that strychnine was the cause of death. Dr. Herapath found arsenic in abundance in the stomach, but no strychnine. He also found traces of arsenic in the liver. If strychnine were taken it never entered the stomach at all. He thinks it probable, however, that the two first packets did not kill her as quickly as she expected, and she took the third packet, but the contents never went further than the mouth, some being ejected in consequence of the bitter taste, and an almond being taken to get rid of this; but enough remained to kill by absorption from the mucous mem-

brane of the tongue. The coroner would not have Dr. Herapath's evidence as he had given no orders for a chemical analysis. Battle's papers, of course, contain strychnia; the others probably consist of arsenious acid.

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY.....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY.....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY.....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY. Royal Medical and Chirurgical Society, 8.30 P.M. Mr. Henry Lee, "On Acute Inflammation of Veins"; Dr. George Harley, "On Intermittent Hæmaturia"; Dr. Dickinson, "On Intermittent Hæmaturia."—Zoological.—Ethnological.
WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Odling, "On the Chemistry of Tissue-Metamorphosis."—Microscopical.—Geological.
THURSDAY. Royal Society.
FRIDAY. Royal College of Physicians, 5 P.M. Dr. Odling, "On the Chemistry of Tissue-Metamorphosis."—Astronomical.—Royal Institute.

TO CORRESPONDENTS.

* * All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

THERE were thirty-nine medical men in the Convention which condemned Louis XVI to death. Of these, seventeen voted for his imprisonment; and twenty-two for his death!

A NEW BIMONTHLY JOURNAL, called the *North American German Medical Journal*, printed in German, has just appeared under the editorship of Dr. Meisburger. It is printed at Buffalo.

A GOOD MODEL.—The following model advertisement is taken from the *Surrey and Hants News*.

"Doctor P——, Physician and Surgeon, has removed to ——— Terrace, F—— (opposite ———'s Nursery). At home, as usual, for patients, from 9 to 11 morning, and from 6 to 9 evening. Particulars as to his terms can be obtained at his residence. Dr. ——— makes no charge whatever for medicine."

ERRATUM.—SIR: At the bottom of my letter on Epilepsy, in your last impression, I am made to be of Wolverhampton instead of Northampton. I am, etc., S. W. D. WILLIAMS.
Northampton, May 2nd, 1865.

COMMUNICATIONS have been received from:—Dr. T. SNOW BECK; Dr. P. LESLIE; Dr. SIEVEKING; Dr. ALDERSON; Mr. J. S. GAMGEE; Mr. J. T. HESTER; Mr. A. B. STEELE; Dr. GEORGE JOHNSON; Mr. W. J. COULSON; Dr. HILLIER: THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Mr. HARRISON; Mr. STONE; Mr. W. M. CLARKE; Dr. FREDERICK J. BROWN; Dr. E. L. ORMEROD; Dr. W. H. RANKING; Mr. T. J. AUBIN; Dr. H. SIMPSON; Dr. S. W. D. WILLIAMS; Mr. T. ANNANDALE; and Mr. JABEZ HOGG.

SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

T. WATKIN WILLIAMS, *General Secretary*.

Birmingham, May 1865.

ADVERTISEMENTS.

ESTABLISHED 1848.

Mr. J. Baxter Langley, M.R.C.S.
Eng. (late of King's College, London), PROFESSIONAL AGENCY, 50, Lincoln's Inn Fields, W.C.

Death Vacancy.—In Devon, in
a thriving Market Town, private Practice of deceased, £435 on three years' average. Appointments £45, secured to successor. To secure an immediate successor a small premium would be accepted. Address "S., 1156," Mr. Langley, as above.

In a good Cathedral Town.—For
transfer, a good family Practice, established ten years. Patients wholly of the upper and middle class. No club or parish appointments. No obstetric fees under £1 1s. Good house and garden. Expenses very small. Receipts between £500 and £600. Further investigation permitted, and a satisfactory introduction given. Premium £550. Address "S., 1155," care of Mr. Langley, as above.

In one of the best Towns in
LINCOLNSHIRE.—For transfer, a family Practice, the cash receipts in which are about £500. Patients—good farmers, tradespeople, etc. The locality is healthy and picturesque. Three months' introduction. For terms, etc., Address "S., 1155," Mr. Langley, as above.

In a pleasant Suburb in London.
—For transfer, an excellent and improving family Practice. Receipts last year £630. The books have been submitted to Mr. Langley, who can testify to the *bond fides* of the statements of the vendor. Six months' introduction. One year's purchase required. Address "S., 1106," Mr. Langley, as above.

Country Practices. Mr. Langley
begs to call the attention of young professional men seeking openings for practice, to his register, which, at present, contains a large number of very eligible openings, death vacancies, etc., in the country (with and without public appointments), requiring the investment of only a moderate amount of capital, yet offering a good prospect of fair and prompt returns. Applicants may rely that nothing will be recommended as an investment which Mr. Langley does not believe to be *bond fide* and suited to the circumstances of his clients.

Weiss's Illustrated Catalogue,
containing nearly 800 engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price, 5s. 6d. Straud, London.

"This catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced, and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour which we are glad to see strictly observed in this catalogue."—*Lancet*, September 12th, 1863.

An Inquiry

INTO THE

NATURE OF THE CHANGES CONSTITUTING FATTY DEGENERATION OF THE HEART.

BY

EDWARD L. ORMEROD, M.D., F.R.C.P.,

PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

In the medical address delivered at Cambridge last year, I endeavoured to shew that fatty degeneration of the heart was a pathological and not merely a chemical process imitable in the laboratory by artificial means. The experiments then adduced seemed fairly to justify the conclusions:—1. That fatty matter cannot be made from the muscular tissue of the heart by any of the received processes for converting animal substances into adipocere; indeed, that, on the contrary, the fatty matter of adipocere is derived from the fat already existing in the tissues operated on, and is not a newly formed substance. 2. That though the first stage in fatty degeneration and chemical decomposition be the same, both alike inducing so-called granular degeneration, yet that, so far, there is no fatty formation in either process.

The present inquiries were instituted with a view to determine more exactly the nature of this granular degeneration. In the first instance, my attention was directed to the muscular structure of the heart, as the tissue in which granular degeneration is most characteristically displayed. A more extended observation, however, seemed to show that the laws of degeneration are the same for both species of striated muscular fibre, the voluntary muscles and the heart alike. The results indeed are modified by the structural differences between the two kinds of fibre to a certain extent; but these very differences, instead of disproving in any way, rather help to prove more clearly the general identity of the process of degeneration in them both, allowing us to test the correctness of our conclusions by reconsidering them from a different point of view.

It is, however, rather as supplementary to the observations on the heart, than as having an independent value of their own, that I have brought forward any observations on fatty degeneration of the voluntary muscles. Our knowledge of this subject is as yet imperfect, as regards the mutual relation in which the successive changes stand to each other. However distinctly we may recognise the several phases, we cannot yet arrange them so as to present a continuous history of the disease, from its first beginning to the complete obsolescence of the muscular tissue. Their pathological meaning, too, is not altogether clear at present. Perhaps they may express merely fatty degeneration; but their frequent connection with typhus, as Dr. Zenker has shown in his admirable monograph (*Die Veränderungen der Willkürlichen Muskeln in Typhus Abdominalis*), and with cancer, as he generously reminds us that Dr. Bennett (*On Cancer*, p. 105) had previously noticed, favours the belief that they may have some special connection with particular forms of disease; and at least there is need of more observation to bring our know-

ledge of the microscopic pathological anatomy of voluntary muscle up to the level of that of the muscular structure of the heart.

Fatty degeneration of the muscular fibres of the heart commences by a change known as granular degeneration. I believe that the term granular disintegration would more correctly express the nature of this change; for the appearance is due to a disintegration or disruption of the sarcolemmal elements contained in the primitive fasciculus. This is the first step towards fatty degeneration. It may be induced by other than pathological causes; namely, by commencing putrefaction, and by decomposition under artificial conditions. The arrangement by which the natural process is most readily imitated, is a prolonged maceration in dilute alcohol. By this the sarcolemmal elements are disintegrated along the longitudinal lines of cleavage—to adopt Mr. Bowman's nomenclature. By prolonged maceration in dilute nitric acid, disintegration is effected in both the longitudinal and transverse directions, and the fasciculus is resolved into small squarish powdery fragments. By varying these processes the results may be modified; and by such means the muscle may be disintegrated or disrupted at will, in either direction and to any extent, independent of any fatty degeneration. And we may thus obtain an insight into the nature of the pathological process, where, from the disintegration not having been pushed as far as in our chemical experiments, the appearances are more equivocal.

The granular fasciculi which result from the pathological process, or from any of these chemical reactions pushed only so far as to imitate it, require a high power to display the exact nature of the changes which have taken place. With a magnifying power of about 240 diameters only, it seems as if the transverse striæ had been replaced by longitudinal rows of dots, divided here and there by other rows of larger and darker dots, and by fine lines. These appearances are explained by the application of a power of 450 diameters or more, which shews that the transverse striæ are not really lost. They are paler indeed than in the normal condition, but they preserve their normal distance from each other. The primitive fasciculus seems to be split into ribbons of unequal width by longitudinal fissures interrupting the transverse striæ. In consequence of these interruptions, such striæ as catch the eye with a lower power seem to run into rows of dots, and this false impression is heightened by the rows of larger and darker dots which occupy some of these longitudinal fissures.

The examination of this altered structure of the heart is much facilitated by the use of glycerine, according to Dr. Beale's directions. Unfortunately, this medium, so very useful in unravelling the fasciculi, greatly obscures their transverse markings. But this is remedied to some extent by the application of ether, which dissolves away the large dark dots in the fissures, and brings the transverse striæ again into view, drawing them at the same time nearer to each other, so that eight now occupy the space where only six were found before the ether was applied. As the various objects in the field come out more distinctly, some longitudinally striated fasciculi may perhaps be recognised among the degenerated fibres; and from the ends of some of these which have been broken during the manipulation, ragged filaments may be seen projecting, just as in degenerated voluntary muscle. These filaments vary in length and breadth, but all have the transverse markings; some are broader; some so fine that they might be fairly said to represent the old so-called ultimate fibre of muscle, their dimensions scarcely admitting of the presence of more than a single row of the component

granules. It is scarcely necessary to remark that, though the demonstration of these changes is facilitated by the use of these reagents, the changes are wholly independent of their employment. Without the use of ether, the transverse striæ may be brought again into view by means of a condenser and a narrow stop.

As the process of degeneration advances, the longitudinal fissures become fewer and more distinct, and the granules, too, larger, fewer, and less regularly arranged in rows. All traces of transverse striæ disappear, the longitudinal markings fade in the progress of the disease, and the primitive fasciculus now appears as a granular mass, preserving only its original outline. Now fatty degeneration has fairly begun, and oil globules are to be seen in and about these altered fasciculi, apparently resulting from the coalescence of the larger, darker dots above mentioned.

Life does not last long enough with a heart thus involved, for one to be able to say exactly what is the ultimate end of fatty degeneration of its muscular structure. The disease will generally be found to have advanced furthest in the little pale specks to be seen on the inner surface of the left ventricle. Here single fasciculi sometimes present partial dilatations, but more commonly they shrink away. Bundles of irregular shrunken fibres, which occur in connection with fatty degeneration, or the cicatrices which appear to the unassisted eye, may probably represent the obsolete muscular fibres in which this process has been completed. But this termination of fatty degeneration is more familiarly known in the voluntary muscles. In one bundle of the heart's fibres, as in a single voluntary muscle, there is nothing to hinder the completion of the process; but, as might have been anticipated, the more widely the degeneration is diffused through the heart, the less progress will it be found to have made.

The ultimate results are mostly the same, whether the disease commenced, as is usual, from the interior of the heart, and in connection with cachexia or anemia, or whether it have originated in inflammation and have started from the outside. But the steps of the process, or at least the collateral phenomena, are not absolutely identical in all these cases. In fact the specific pathological influence does not seem always to cease with the first injury to the fasciculus. But the exceptions to the ordinary mode of progress of the disease requiring particular notice are not many.

One striking exception occurred in a poor girl who died of pyæmia. In the muscular structure of her heart were red patches, looking like ecchymoses, of a deep purple mixed with grey in the centre, becoming gradually paler at the edges. In the grey part there was a mixture of pus and blood, with fragments of muscular fibres. Surrounding this was a zone, in which the muscular fasciculi had lost all traces of striæ both transverse and longitudinal; they were simply granular all over. Then, for a space, the fasciculi were longitudinally striated, as in degeneration of the voluntary muscles. Outside this the muscular structure presented the normal appearance. Within the radius of two or three lines the chief appearances of degeneration of voluntary muscle were perfectly reproduced in miniature. The only character which was not adequately represented here, namely, the redundancy of small nucleolar bodies, was very strikingly shewn in the heart of a boy who had fatty degeneration commencing from the outside, consequent on rheumatic carditis.

Generally, it may be said that the process of fatty degeneration of the voluntary muscles is the same as that of the muscular structure of the heart. Yet

there are readily appreciable differences in the details of the process in these two tissues respectively. These differences seem referable to a certain extent to the structural differences of the fibre, and notably to the greater development of the sarcolemma in the voluntary muscles. The first stage of fatty degeneration of the voluntary muscles, as far as I have been able to satisfy myself, is characterised by swelling of the affected fasciculi. For a greater or less length they appear uniformly dilated to about twice the size of the healthy fasciculi, smooth on the surface, seemingly wanting the transverse striæ, but streaked longitudinally; and from the broken ends of each such fasciculus loose strings hang out like the strands of a rope, as if it had undergone thus far, complete longitudinal disintegration. A higher power shews here, as in the muscular structure of the heart, the existence of the transverse striæ, only paler than natural. They are not interrupted by the longitudinal markings. They are approximated to half the normal distance, sixteen of them occupying the same space as eight do in a healthy part. Ether does not cause them to approximate more closely, though it seems to shrink up the fasciculus; and it displays the longitudinal markings very clearly, at the same time that it extracts fatty matter from its interior.

This longitudinal cleavage would seem to hold nearly the same relation to fatty degeneration of voluntary muscle, as granular disintegration does to that of the heart. Nearly, for it passes more directly into fatty degeneration than the corresponding change in the heart does, ether readily extracting oil from the streaked fasciculi. And it is more specifically a pathological process, being much less readily imitable by any artificial reactions. For chemical decomposition and putrefaction do not induce this particular appearance, but seem, as far as I have observed, to pass over it to a further stage, converting the fasciculus into a finely granular mass, which retains only the outline of its former structure. This process of conversion may be traced in some of the transverse striæ which have survived the rest. These appear distinctly granular, broad, and uneven; as if falling to pieces under the action of the dilute nitric acid, which has disintegrated the sarcolemmal elements elsewhere. The striæ seem to persist longest just beneath the sarcolemma. Some fasciculi which appear granular, owe this deceptive appearance to the striæ on the two opposite sides of the flattened fasciculi crossing each other diagonally, the regular arrangement persisting on the surface for a while after the sarcolemmal elements in the interior have been deranged or dissolved entirely away.

Sometimes these large, pale, waxy-looking fibres occur alone; more commonly, however, broken fragments of fibres are found mixed with them, swollen, like them, to twice the size of the neighbouring healthy fasciculi, but marked in a different way. Some of these are minutely granulated, the fasciculi thus marked being much more brittle than those which are longitudinally streaked. Others are neither granulated or streaked, but cracked or broken transversely, and often connected at either end with a string of sarcolemma, as if they had partially escaped from their investing membrane. They have a singular affinity for the colouring matter of carmine, which tints them more deeply than any of the other structures which the altered tissue presents. Besides these, the field appears to be sprinkled over with little nucleolar bodies, some few of which are the nuclei of the muscular tissue; others, more numerous, are apparently the rudiments of fibro-cellular structure; others are of uncertain nature; and many are undoubtedly collections of oil-globules, arranged like rows of squarish beads. These are removed by

ether, which clears the field a good deal, while acetic acid has very little effect in this way. And with these are a number of loose oil-globules, which have been set free during the manipulation of the tissues. The changes which occur in connection with typhus, as figured by Zenker, are precisely those which I am now speaking of as constituting the various stages of fatty degeneration. (Taf. iii, figs. 1-2; taf. iv, fig. 1.)

Not to lengthen these remarks needlessly, I may yet venture to add, in a few words, to this statement of facts, the conclusions which seem fairly deducible from them.

I believe that the first step towards fatty degeneration of muscular tissue is disintegration of the sarcous elements into filaments or discs, as circumstances may determine. The actual fatty degeneration is secondary to this, and is a consequence—not a cause—of the disorganisation (the functional death) of the fasciculus. In the further changes and ultimate obsolescence of the fasciculus it may play an important part, particularly by resolution of the sarcous elements in the oily matter infiltrated among them through the sarcolemma; but the disorganisation of the part precedes its degeneration.

Inflammation, anæmia, cachexia, want of nutrition, and all the other causes to which fatty degeneration of the heart has been ascribed, have thus much in common that they disorganise the muscular tissue. The disintegration and the fatty degeneration which ensue, may be modified by the abiding influences of the original exciting cause of the disease, but they are transacted by the ordinary agency of the living body quite irrespective of these various possible causes. The actual fatty degeneration depends on the amount of fatty matter in the blood available for this purpose; and it is conceivable that, for want of an available supply of fatty matter, disintegration should not be followed by fatty degeneration at all. Indeed, this seems actually to occur sometimes; the change under certain circumstances does not pass beyond the stage of so-called granular degeneration.

Now, if this be true, a question suggests itself, whether this explanation be limited to fatty degeneration of muscular tissue, or whether it has a wider bearing. For instance, is fatty degeneration of the liver or kidney an infiltration of disorganised cells with oily matter, or a destructive accumulation of oil in healthy cells? Further, is the physiological accumulation of fat in adipose tissue explicable on the same principle, namely, that healthy cell-walls, sarcolemma, or other such tissues are impermeable to fat, and that the accumulation of fat in any part implies that the vitality of the tissue containing the fat has been lowered?

I am not prepared to offer any answer to this question at present. It demands as particular an inquiry into all possible cases of fatty accumulation and degeneration, as I have endeavoured to carry out in respect of the single case of the heart. Beyond all others, the instances of acute fatty degeneration of the brain and liver need careful investigation, more than those where this principle obviously applies. The study of these and such instances is more likely to lead to a just estimate of the value of this principle, than an accumulation of cases where the facility of its application tends to conceal its deficiencies.

TYPHUS IN MALTA. A severe form of typhus fever has lately been very prevalent in several of the country districts in Malta. Its virulence has now abated; and, from a report made by order of the Governor, it appears that it was due to overcrowding in ill-ventilated apartments.

Original Communications.

VENESECTON IN DISEASE.

By W. O. MARKHAM, M.D., F.R.C.P., Physician to St. Mary's Hospital.

THERE is an old and very true saying, that no reputation is better than a bad one; and the saying precisely fits the article venesection, as a remedy in disease. The true estimation of this remedy is, I am satisfied, not admitted, mainly because of the evil reports which attach themselves to the word through its historical connexions. I have no doubt whatever, that if venesection were a modern invention, it would be in much more frequent use than it now is. The remedy thus suffers; and in two ways.

1. The proper uses and right application of venesection are not generally recognised, because the erroneous idea which was attached to its employment in past days is still very much attached to it now; viz., the idea that by its use the supply of aliment to the fire which is raging in and consuming the inflamed structure is cut off.

2. It seems to be still generally assumed, as it was in former days, that the use of venesection is synonymous with the disuse of what are called restoratives; and that those who employ venesection must, of necessity, also at the same time employ low diet, purgatives, and whatever else is comprised under the old idea of antiphlogistic.

So long as these erroneous ideas, which naturally run together in men's minds, prevail; so long as venesection and low diet are regarded as things necessarily connected; so long as venesection is employed with the idea of directly controlling the inflammatory process *in loco* by cutting off the fuel which feeds the flame—so long, in my opinion, will venesection be in bad repute.

My distinguished friend, Professor Bennett of Edinburgh, has not altogether emancipated his mind, as it would seem, from the ideas here referred to. In a very instructive paper lately written by him, On the Treatment of Pneumonia by Restoratives—a paper which appears to have been called forth by a lecture on Venesection by myself lately published in these pages—Professor Bennett gives the result of his long experience in the treatment of pneumonia. He does so to show the good effects of the restorative treatment; and because he observes, “that an effort is being made to restore the dangerous practice of bleeding in pneumonia.”

Perhaps, in the lecture referred to, I somehow failed to make my meaning clear. I would, therefore, in explanation, wish to say, that Professor Bennett has quite misinterpreted my meaning; and that I really believe there is *au fond* very little difference of opinion between us as to the practical use of venesection in pneumonia.

In the first place, I have not recommended venesection as a cure for pneumonia. According to my views, venesection has no directly beneficial influence over the local inflammation, and is not used to cure the pneumonia; but solely and wholly to relieve certain accidents which have arisen out of the pneumonia; viz., the congestion of the heart and of those portions of the lungs which are not the seat of inflammation. To administer restoratives, therefore, both before, during, and after the venesection, is a perfectly legitimate practice. To suppose that the employment of venesection means the non-employment

of "restoratives"—to regard the two things as antagonistic—is to go back a hundred years for our principles of pathology.

In the sense inferred, therefore, it is quite a fallacy to say, that an "effort is being made to restore bleeding in pneumonia." I do not look upon venesection as of any use *quoad* the pneumonia; nor do I believe it has any directly beneficial influence over any inflammation of the body. I advise its employment in pneumonia for the sole purpose of relieving the patient from the pain and perils of asphyxia—from the dangers of a defective or impeded respiratory action; and, consequently, *only in those cases of pneumonia in which the respiration is seriously interfered with.* But such cases are exceptional ones in pneumonia; exceptional, therefore, also, is the application of venesection in pneumonia.

A consideration of these plain facts will, I am sure, satisfy Professor Bennett, that to compare the employment of venesection, combined with the proper use of restoratives, as here recommended in the treatment of a few severe and exceptional cases of pneumonia, with the employment of venesection, together with blistering, purging, vomiting, and starvation, in all cases of pneumonia—is to bring together in argument things of totally different signification.

Happily, I find proofs in Professor Bennett's own paper, that he himself takes very much a similar view of the matter. He admits that the employment of venesection in certain cases is of service. In fact, he says very much what I myself have said. His words are:

"No doubt, also, small bleedings to the extent of eight or twelve ounces, give relief; but in debilitated persons are dangerous; and in all tend, by weakening the strength at a period when the depressed system is struggling to regain its equilibrium, to prolong the convalescence and favour dangerous sequelæ. Still a small bleeding may be employed as a palliative, with caution, to relieve engorgement of the lungs and congestion of the right side of the heart, although it is very rarely required."

In conclusion, I would just like to ask for the proofs, that there is danger in a moderate loss of blood in any case of pneumonia. Whence has Professor Bennett obtained the practical evidence which has satisfied him of the truth of his assertions of the danger? Assuredly, he has not obtained the evidence from his own observation during the last twenty-five years, as he himself does not employ venesection; and assuredly, also, he can draw no fair or legitimate conclusions as to the dangers of venesections, or as to the true effects of venesection, by judging of it from the results of practice of those who have employed it in conjunction with a starving diet, and calomel, and purging, and blistering.

When Professor Bennett talks of the dangers attending the loss of a few ounces of blood in pneumonia, I cannot help asking him to explain how it is that we daily see so many patients in hospital, surgical and medical, the feeble as well as the strong, losing without apparent injury—and often, and especially in lung- and heart-diseases, to their very great relief—large quantities of blood? What proof do these very numerous facts daily under our eyes afford of the danger of the loss of a few ounces of blood?

And one other question I would put to my friend. Of what real use to us are statistics of the results of treatment of pneumonia, as indicative of the comparative remedial value of bleeding and of restoratives, when the statistics are founded on cases in which the bleeding was employed in conjunction with starvation? Almost all the statistics, drawn especially from French authors, are of this kind, and therefore valueless. Surely, to say that venesection

is the cause of the great mortality in pneumonia, in cases where the patients were at the same time both bled and kept upon starvation diet, is a very illogical and inadmissible conclusion.

ON PUERPERAL FEVER.

By T. SNOW BECK, M.D. Lond., F.R.S., Member of the Royal College of Physicians, London.

[Read before the Obstetrical Society of London, February 1st, 1865.]

[Concluded from page 460.]

If the views which have been deduced from this examination of these cases be correct, it follows that one of the principal objects in the prevention of puerperal fever will be to procure a complete and permanent contraction of the uterus after the birth of the child and the expulsion of the placenta.

In the majority of cases of parturition, the uterus contracts readily and firmly; but, in other instances, I must admit that I have found it much more difficult to obtain the complete and persistent contraction than is generally supposed. In our most esteemed works on midwifery, the subject is treated very shortly. For example, the accoucheur is directed to lay his hand on the abdomen, in order that he may satisfy himself that this viscus "is in a safe and proper state of contraction." (Merriman.) Again: "The hand should be placed upon the abdomen to ascertain (from the size of the uterus) whether there are twins; if not, we may proceed to apply the binder, which should embrace the hips inferiorly and the whole abdomen." (Churchill.) Or: "The left hand should be immediately applied over the fundus, in order to maintain a moderate pressure upon the uterus while it is descending towards the pelvis. This should never be neglected; because it ensures a uniform contraction of the uterus, and often the expulsion of the placenta into the vagina." (Murphy.) "In ordinary labour, friction is made with the hand over the hypogastric region: this is repeated from time to time, in order to excite the contractility of the tissue of the organ, its 'degorgement,' and the expulsion of any coagula it may contain." (Cazeaux.)

Certainly other means are recommended on the occurrence of hæmorrhage, or in exceptional cases; these means being, to firmly grasp the uterus with one hand, whilst with the other we apply cloths dipped in cold water suddenly to the genitals; to use cold enemata and cold drinks; to pour cold water from a height on the abdomen; to apply pressure by means of a pad placed beneath the binder; to administer ergot of rye; to have recourse to galvanism or electricity; to irritate the organ to contraction by introducing the hand into its cavity; and, lastly, to inject cold water into the uterus. I must, however, admit that in my experience most of these means have failed to effect the object in view. I have not found the external application of cold, cold enemata, cold drinks, or any amount of pressure which could be applied by means of the binder, of much practical good in effecting a firm and persistent contraction of the uterus where there has been any tendency to a lax state. When carefully applied, the binder is, no doubt, a source of much comfort to the woman who has been recently delivered, by supporting the relaxed state of the abdominal walls and giving support to the back. But I have found so little real good from any amount of pressure which could be employed through this means, with the aid of pads or otherwise, whilst the difficulty of applying it and the discomfort it occasioned were so considerable, that I have ceased to employ it for this purpose. When coagula form in the interior of the organ, it is often

required to introduce the hand to remove them; and no doubt the hand is a powerful stimulant to induce contraction, especially when aided by firm external pressure on the uterus, through the means of an assistant. But even these too often fail, as they notably did in the first case recorded; and, when they do induce contraction, it is often not persistent. I have had little experience in the injection of cold water into the cavity of the uterus, or in the application of electricity; yet I do not doubt but they are efficient means to induce contraction. The most trustworthy agent appears to be the local application of cold by means of ice passed up to the orifice of the uterus, and the administration of ergot of rye. Pieces of ice of the size of a hen's egg, or rather larger, are passed up to the orifice of the uterus, and held in that position. The first one or two pieces quickly dissolve, in consequence of the heat of the part; but, when this becomes partly reduced, a firm and persistent contraction is generally the result, though occasionally even this powerful agent will fail. And I may add that, although I have used it now in a great number of cases, I have never seen the slightest inconvenience to result from its employment. Combined with the application of cold direct to the uterus, I have found the administration of ergot of rye a useful addition. It appears to ensure the firm contraction of the organ, and, what is of much importance, to render it persistent.

For some years past, I have carefully observed the state of the uterus immediately after childbirth, considered as a means of obviating that enlargement of the organ which too frequently follows childbirth or abortions, as well as preventing many of the ills to which parturient women are liable. And I am firmly convinced that many of the dangers and evils which women suffer after delivery may be prevented by procuring a complete and persistent contraction of the organ. It would appear that, when the vessels are at all pervious to the circulation of blood within them, the presence of this fluid interferes with those changes which are necessary to reduce this organ to its condition previous to impregnation; and, to this end, I have been led by experience to administer the ergot of rye in all cases after the removal of the placenta, even if its employment was not indicated before this period of the labour. The combination I have found most useful has been that of the tincture of Indian hemp, powdered ergot of rye, and borax, mixed with some stimulant and aromatic. One to four doses of this mixture has been given at one or two hours' interval, according to circumstances, and with the best results; for, although they occasion a considerable amount of after-pains, yet the comfort afterwards experienced, and the pleasing convalescence, more than compensate for the pains induced.

I believe it is generally considered that, when the uterus is so contracted as to prevent any further hæmorrhage, this is sufficient to ensure the safety and well-being of the woman. But I have found that it is necessary to carry the contraction beyond this point before we can consider that we have ensured the safety, much less the well-doing, of the parturient women; and I have been led to think that this arises in many instances from a relaxation of the muscular tissue subsequent to the removal of the placenta, and after it has been fully contracted. The second case recorded appears to be an example of this condition of the organ; for here the labour progressed naturally; no hæmorrhage occurred; yet the uterus was found, after death, to be in so relaxed a state as to permit fluids to be injected along its vessels from the large abdominal veins.

If these views be confirmed by the experience of

others, the treatment of women immediately after delivery appears of much more importance than has been commonly supposed; and this extends to the diet, as well as to other matters. It would appear, by reason of a general belief that puerperal fever and other diseases of childbed women were purely inflammatory affections, which required to be treated by large bleedings and means calculated to prevent or reduce inflammation, that women during the puerperum were kept on a low and depressing diet. But these opinions are now generally considered to have been erroneous; and that, instead of keeping the female to a low and depressing diet, she requires a good diet and nourishing support, in order to relieve her from the physical fatigue and mental anxiety of the labour, to restore her health from the waste occasioned by the previous months of pregnancy, and to enable her to pass through those subsequent changes which have yet to take place. To this end, it would appear that a liberal diet is necessary, and, in some cases, even the addition of a stimulant. Of course, the regulation of these matters depends much upon the previous habits and state of health of the woman, as well as upon the season of the year and other incidental circumstances; but I am convinced there is not that danger in a liberal supporting diet which was at one time so generally believed, and that a stimulant similar to the "caudle" of old may frequently be given with much advantage. This appears to be confirmed by the remark of Dr. Ferguson in his valuable essay already referred to. "The late matron of the hospital," he observes, "Mrs. Wright, remarked the effect of the hospital diet on the patients as often very depressing; and knowing, from the habits of this class of people, that gin was to many of them the common substitute for meat, she was induced to change the hospital dietary for a caudle in which gin was the staple. *We shortly after this had a marked diminution in the intensity of the epidemic.*" (P. 168.)

It is a general remark, that primiparae are more liable to be attacked with puerperal fever than women who have previously borne children; and many explanations have been offered to account for this fact. But it appears to have been overlooked, that much of this greater liability may be attributed to the circumstances which are brought into action in a first confinement. In many women, the uterus does not take on the changes consequent upon pregnancy and delivery with the same degree of completeness, so to speak, or with equal facility, as in others. In some, the uterine organs are so badly developed as never to become impregnated. In others, the uterus appears to be only capable of a certain amount of development; for, after it has grown for a few months, it becomes thin, appears overstretched, and in a short time abortion takes place. I have known women to miscarry time after time, and generally about the same period of pregnancy, from apparently this cause. In other cases, again, the female goes the full period; but the uterus appears so ill developed as to be incapable of power sufficient to expel the child without artificial assistance, or of maintaining a sufficient amount of contraction afterwards to ensure the safety of the mother. The aptitude, as it has been termed, to bear children, is thus sometimes wanting in females; but this is only discovered when they become pregnant with the first child. Another source also exists in the fact that first confinements are, as a rule, more laborious and more exhausting than subsequent pregnancies. And to these causes we may not improperly attribute a large amount of the greater proclivity to this disease observed in primiparae.

May we not attribute to the various causes which

have been glanced at the greater frequency of puerperal fever in hospitals, and amongst the poorer classes who are attended by midwives? I understand it to be the rule in these institutions, that, after the child is born, the soiled things are removed, a binder is applied, and some gruel given. If the after-pains be severe, a soothing dose of laudanum is then administered. Little or no attention appears to be paid to ensure the complete and permanent contraction of the uterus; and as little attention is paid to the diet necessary to meet the habits and state of health of the women who frequent these institutions. Is this the explanation to the following passage from Dr. F. Churchill's learned introduction to the Sydenham edition of *Essays on Puerperal Fever*? "I would remark, then, in the first place, that there appears some special connexion between the epidemics of puerperal fever and lying-in hospitals. I do not mean exactly to assert that these epidemics always originate with, and are kept up by, the hospitals; but I refer to the fact that we have no record of any epidemic independent of them in early times. . . . No doubt it has since been observed in private practice in London, Edinburgh, Sunderland, Leeds, etc., etc.; but its extent in these cases is, after all, comparatively limited, except in very sickly times; and it is often confined chiefly to the practice of a few individuals. In Dublin, the higher ranks have been singularly free from attacks of this disease. Dr. Joseph Clarke, whose account of puerperal fever as it appeared in the hospital is here reprinted, practised for forty-four years in this city, during which time he attended 3,847 cases of midwifery, and yet in that number he met only three cases of acute peritonitis, and three others whose disease appears doubtful, but which might possibly have been uterine phlebitis. And this singular fact, which is to me inexplicable, is confirmed by the experience of Drs. Collins, Johnson, and others, as they have assured me." (P. 32.)

When, in spite of all the care we may take of the woman during her labour, and for the first twelve hours or so afterwards, poisonous infection of the system occurs, the treatment becomes essentially modified. And here the remarks of Cruveilhier, as quoted by Dr. Ferguson, apply with much force: "What treatment shall we oppose to purulent infection? To this question experience is as yet dumb, while theory would seem to point to diffusible stimuli and tonics; to ammonia, quinine, and to sudorifics; to hot external applications; to the vapour-bath; to purgatives, especially to emetics; to tartarised antimony, in large doses; to vesicatories; and to strong diuretics. Calomel has been extensively employed to create a fluxion from the intestinal mucous membrane; but all these means have failed as signally in my hands as in those of others. Yet when the injection of putrid matters into the veins of living animals has been followed by abundant and very fetid evacuations, they have usually got well. It is a fundamental fact of pathology, that the intestinal canal is chiefly affected in diseases caused by any miasmata. The ancients expressed this truth by saying that the intestinal canal attracted the poison of febrile diseases. I am certain that diseases resulting from purulent infection would not be stamped with the seal of incurability, and that nature, seconded by art, would triumph in the majority of cases, if the pus, which is incessantly renewed, did not incessantly renew the sources of infection."

The principles of treatment, which the review of these cases would suggest, would then appear to be: (1) to prevent the further injurious impregnation of the system, either by obstructing the further flow along the uterine sinuses, or by removing the noxious

fluids from the interior of the uterus; (2) by supporting the system during the struggle in which it is engaged, and by meeting any accidental complication which may present itself; and (3) perhaps a further source of treatment is now afforded which may enable us to counteract, to some extent at least, the deleterious impregnation which has already taken place.

1. The metamorphosis or disintegration which takes place in the muscular tissue of the uterus after childbirth prior to its removal do not, it is said, commence before the fourth or sixth day; and, as the symptoms of injurious impregnation usually show themselves on the second or third day, it is not improbable that means might still be found to induce that further small amount of contraction in the organ which is necessary to close effectually the uterine sinuses. A continuous current of electricity, of low intensity, might have this effect. But I fear the other means already adverted to do not afford much chance of success; for it is undeniable that a truly efficient agent to induce the permanent contraction of the uterus is still a great desideratum.

The same object may be attained by the coagulation of the blood in the sinuses; and there is good reason to believe that this is not unfrequently the result of noxious fluids being mixed with the blood. We also know that any great depression of the system favours this coagulation; and it is not impossible that the copious bleedings which are said to have been employed with such good results may have acted in this way. "When I took away," says Dr. Gordon, "only ten or twelve ounces of blood from my patient, *she always died*; but when I had the courage to take away twenty or twenty-four ounces at one bleeding in the beginning of the disease (i. e., within six or eight hours after the attack), *the patient never failed to recover*." But, whether this be the result of these copious bleedings or not, there are few, I think, at the present day, who would have the boldness to have recourse to them, or who would forget the experience mentioned by Dr. Farre in his *Journal*, and quoted by Dr. Gooch. "At the East End of London, not far from the river, the disease (puerperal fever) proved still more fatal during the month of March (1825). One surgeon informed the editor that he had lost seven, another four, in all of which the disease was treated at the instant of its formation by active blood-letting. A physician-accoucheur, who attended in consultation many of these cases, stated to him that, out of thirteen cases, eleven died; that all which had been bled died; and that the only two which recovered had not been bled, having been treated by turpentine." "The experience of the last four years has brought me," observes Dr. Gooch, "to this conclusion, that the sanguine hopes which were entertained, a few years ago, that the peritoneal fevers of lying-in women are always of an acute inflammatory type, and always to be cured by early bleeding and purging, as they were not borne out by the reasoning employed, so they have not been confirmed by subsequent experience." (*On some of the most important Diseases peculiar to Women*.)

The removal of the noxious fluids from the interior of the uterus appears to afford an important means of treatment, and to furnish one of the objects mentioned by Cruveilhier. "I am certain that diseases resulting from purulent infection would not be stamped with the seal of incurability, and that nature, seconded by art, would triumph in the majority of cases, if the pus, which is incessantly renewed, did not incessantly renew the sources of infection." But, in using these means, the remarks of Dr. Denman, though written so long ago, should be borne in remembrance: "I have seldom attempted to inject

medicines of any kind into the vagina and uterus; though, from a consideration of the state of these parts, and of the fetid humours discharged from them, it is reasonable to expect that emollient or gentle detergent injections might be useful. However, if these are advised, there should be great caution both in the composing and administering of them." (P. 60.)

On this subject, M. Piorry remarked, in the discussion on the treatment of puerperal fever before the Imperial Academy of Medicine at Paris in 1858: "It is indispensable to cleanse, by means of injections carefully employed, the uterine cavity from blood and putrid sanies which it contains. During five years I have not seen one female perish who has been attacked with puerperal peritonitis; and, in all women who have been confined, uterine injections have been carefully employed." (*Bullet. de l'Acad. Impériale de Med.*, vol. xxiii, p. 461.) M. Hervez de Chégoin also observed: "The injections of the uterus, of which I have spoken, ought to be placed in the first rank (in the treatment); and, as I have said, their efficacy depends upon their proper use—that is to say, the care of the physician to seize the suitable moment. It ought to be directly upon the occurrence of the first indication, so slight and so important, and upon which I have fixed the attention." (P. 470.)

The substances which offer the greatest probability of success are a weak solution of the sulphites or hyposulphites in tepid water. A long elastic tube may be passed to the fundus of the uterine cavity, and the interior of the organ carefully washed out with a weak solution of sulphite or hyposulphite of soda, by means of the ordinary enema apparatus; care being taken that no force be employed, and that all air be excluded from the apparatus prior to its introduction, by passing the fluid through it several times. The noxious fluids may thus, to a great extent, be removed; and, should any of the injected fluid gain entrance into the uterine sinuses, it will probably be more beneficial than injurious. This washing out of the uterine cavity may be repeated each day, or at shorter intervals, according to the circumstances of the particular case.

2. The means to support the system during the struggle, and to meet any accidental complication, are too well known to require any remarks.

3. As Cruveilhier observed, after detailing the various means employed to combat purulent infection, "all these means have failed as signally in my hands as in those of others." But, since that period, the researches of Dr. Polli of Milan, and of Dr. Mariano Semmola, upon the action of the sulphites, have rendered it probable that these agents may be found of much value in the treatment of injurious impregnation of the system, even after this has taken place. Both these observers concur in the opinion that these agents possess a remarkable power in putrid infections of the system, when they are not the result of specific disease. They are given in divided doses, to the amount of from three to four drachms in the twenty-four hours; and the sulphites of magnesia or lime would appear to be the most suitable for internal administration. I have given lately these remedies in some cases, in doses of one scruple to one drachm every two or three hours, with encouraging results; but my experience of them is too limited to admit of any opinion.

In concluding these imperfect observations, I would remark, that I am fully aware there are many points of much interest in this important subject which have not been touched upon; but to notice all the points would have been to go over ground which has been most ably handled by others, as well as to

render this notice too lengthy. No one can be more convinced than I am of the imperfect nature of the present communication; but I thought it better to submit the observations as they are, to be tested by the experience of others, than to wait until I had accumulated further facts myself. Of the facts, I believe they will be found to be correct; but the deductions drawn from them must be tested by further clinical experience and the observations of independent observers.

BATH AND BRISTOL BRANCH.

NOTES ON CANCER: THE ADVANTAGES OF AN EARLY OPERATION IN CERTAIN CASES: CASE OF OPERATION FOR CANCER OF THE NON-DESCENDED TESTICLE.

By W. MICHELL CLARKE, Esq., Surgeon to the Bristol General Hospital.

[Read October 17th, 1864.]

I SUPPOSE that few men have passed many years in the active pursuit of medical practice, without having frequently meditated, and sadly too, upon the subject of cancer. What is its origin, what its nature, what relation does it bear to the patient's constitution, and what to external injury or irritation? These are questions that we must have often put to ourselves; but I need not say to you that they are questions which, in the present state of our knowledge, we cannot answer. Cancer is at this day almost as intractable as to the information it will yield us of its source and nature, and also as to its treatment, as it has been in all medical history.

Indeed it seems, at present, quite useless to spend much time in the consideration of such questions as I have mentioned; although there are one or more, such as the question of the hereditary or constitutional origin of cancer, and its causation by external injury or irritation, about which much may be learned from the writings of various authors, and much that is useful is ascertained.

But, even with reference to these limited points, it must be evident to every one who has seen much of the disease, that the cases which present themselves differ from each other almost as widely as distinct diseases differ. No one can doubt that, in such cases as we not uncommonly meet with, where the disease simultaneously invades many and distant organs, or in such rapid succession that they appear to have been attacked at once, it must have had its origin in a constitutional dyscrasia, and that local irritation can have had but little to do with the production of such a malady; whereas, on the other side, how difficult is it to recognise a diathetic causation when the disease, beginning from a blow or some other injury to an external part, remains for a long time local, and may even be arrested by the interference of the surgeon. And yet such perplexing cases do not only occur, but they present themselves to our observation almost every day.

This great variety in the characters presented by different cases of this terrible disease has given rise to opinions as various upon the subject of its treatment. That there is no medicine capable of curing it, all will allow; but whether in any case surgery should interfere, has been, and still is, argued with very shifting results as to the conclusion.

No doubt this disease is one of our greatest opprobria; and the most enthusiastic professor of medicine within the ranks of legitimate consideration must admit, that no cure by any drug can be avouched for it, although out of the pale of respectable doctors there have been, and I suppose ever will be, people who can cure cancer as readily as any other malady.

The opinion that I have formed is that, although we can do much to assuage, and although we may be permitted very materially to smooth the patient's path to the grave, by removing the frightful pain and the abominable fœtor, and in some other ways, we cannot for a moment stay the progress of the disease by medicine.

The consideration of this matter, in a surgical point of view, presents itself to us in more than one aspect. We may hold that the removal of a cancer, when this object is attainable, is desirable as a means of prolonging life, or we may assert it as a means of relief and comfort. As a means of cure, it is almost, though not quite, as hopeless a proceeding as the administration of medicine. I have myself but very slight hope of ever obtaining a cure by the removal of a cancer; but I think that, in cases where the disease at the time of the operation is altogether local, a prolongation of life may fairly be hoped for. And when we come to view the operation in another light—namely, as a means of relief—I do not think too much can be said of its benefit. The patient's mind is eased of a terrible incubus; and for months, and it may be for years, he may go on in comparative comfort, and at last perish from a form of the disease far less agonising than that in which an external cancer proceeds, through ulceration and exhaustion, to destroy him.

I do not think that the statistics that we have upon this question of the surgical treatment of cancer are of a character to guide us; for before we can judge of the propriety of an operation, we must be made minutely aware of the progress that the disease has made, of its previous duration, and especially as to whether the lymphatic glands be already involved, or whether they still remain altogether free from the disease.

I am certainly, at the present time, more in favour of operating for the removal of cancer in favourable cases—in any, that is, where the disease, so far as can be ascertained, is local at the time of the consultation, where the lymphatic glands are free, and especially where we can cut wide of the disease so as to ensure its entire removal—than I was when I had had less experience of it.

I have had under my notice in the last four or five years, five cases of carcinoma of the breast. Of these, four were operated upon; one died in less than twelve months after the operation; the three others remain alive, and free (apparently) from their disease. In two of them, more than two years have elapsed since the operation; and of these two, one has remained quite well and active, except for an ulcer on her foot, on account of which she has lately come again under my notice, and which was caused by varicose veins, the result of pregnancy twelve years since, and not at all connected with the disease for which I operated. In the second of these cases, the patient seems at present free from the disease, although, in the course of this summer, I removed a small recurrent tumour of the size of a horse-bean from the neighbourhood of the scar. The fourth of the cases was operated upon twelve months ago last June. She is now under my care for a very troublesome neuralgic affection of the ulnar nerve; but shows no other sign of a return of her disease. In one of the five cases, I declined to operate for the

following reasons. The patient was of advanced age (68), and had given symptoms of fatty degeneration of the heart. The cancer, moreover, was a good deal diffused through a large gland, and the removal of it would have entailed a severe operation. I thought, also, that at this age the disease would pursue its course slowly; but in this I was mistaken, for my patient died in about twenty months from the time at which she first consulted me; and, although the tumour never proceeded to ulceration, there was all the disagreeable and harassing distress that is always produced by the existence of a hopeless malady; and it was far more painful to watch the gradual decline of life, than in cases where the disease has been removed, and where, for a time at least, the patient is free from the constant thought of her trouble.

Now, in this form of cancer, the hard cancer of the breast—a form of the disease which as frequently, or perhaps more frequently than any other, comes under our consideration for operation—my experience, and it is by no means limited to the observation of my own cases, is altogether in favour of the removal of the disease; and, in my opinion, it is very unfortunate for the credit of surgery, and also for the sufferers, that the operation is so often so long delayed as it is. I have assuredly no hope, that the extirpation of the disease, however early accomplished, will cure patients of cancer, except in a few rare instances; but I feel very sure that the relief obtained, and the prolongation of life, will be in proportion to the period at which the operation is undertaken. The remarks just made apply even more forcibly to that form of the disease which, attacking the skin most commonly, has been named, and is commonly known by the name of, epithelioma—a form of the disease which is very dissimilar, both in clinical history and in microscopic characters, from the hard and soft cancers.

In this form of the disease, the natural duration is longer, and more also may be hoped from an early operation; and it is often a matter of regret to me to be called to give an opinion in cases where the disease has already advanced very far, and lasted many months or years, and in which no operation has been attempted, or where the disease has been stimulated to more active growth by the application of ineffectual caustics. Such a case was the one of which I have shewn you a photograph, which was kindly taken for me by my friend, Mr. Lansdown. In this patient, the disease began, as it so commonly does, in a wart fourteen or fifteen years before the patient came under my care. It had sometimes appeared stationary; and then had grown more rapidly under the irritation of a blow or some injury, illustrating again a common feature in this form of cancer. He had been under the care of several surgeons, and had been treated with caustic applications. He said that no one had liked to remove it; and certainly, when he came under my notice, it was not a very enticing case to interfere with; but he was suffering so much from the tumour growing along his eyelids and into his eye, that I advised him upon that ground, if upon no other, to have it removed, and to this he gladly enough consented. He went through a severe attack of erysipelas during his convalescence; but got well, and the huge gap that was made in his face filled up, and left a not very visible scar, as may be seen from another photograph that Mr. Lansdown kindly took for me after his recovery. This patient still remains alive, and quite free from his disease. The tumour has been removed more than five years.

Now, in this, and in numerous other cases of epithelioma that I have seen, there can be no doubt that it would be better practice to cut away the disease

much earlier, and at a time when, from the size of the tumour, the operation could be attended with no danger. It seems a cruel thing to let the disease advance to a great size; and yet we are constantly having to deal with instances in which the chief question at the consultation is, whether the mischief has not gone too far to be entirely removed.

The other most common form of cancer—for I have nothing to say about colloid or melanotic cancer in particular—viz., soft cancer—is, as you all know, by far the most hopeless form of this terrible disease. There are a few cases undoubtedly on record in which the disease has been stayed by an operation; but I have never seen any, and yet there are points in which it can never fail to be interesting. The way in which, when occurring internally, it displaces different organs, obstructs the vessels, and presses upon and destroys the functions of nerves, is often very instructive to map out and trace; and, in other cases, great interest attaches to the unusual circumstances of situation in which the disease is developed, as in the following instance, which I shall give somewhat in detail.

I was consulted in January 1862 by a patient who told me that he had something the matter with one of his testicles. Upon examination, I found that both were retained in the groin, and that the right was the seat of an oval tumour, which measured four inches and a half long and three inches and a half broad. It was painless, not tender, and quite free from inflammation. From the first, I suspected that this would turn out to be carcinoma of the undescended testicle; but, as the diagnosis could not be determined at once, and as it was possible that it might only be chronic inflammation, I prescribed iodide of potassium. I continued this until March, when the tumour had increased an inch each way, and looked to the eye much fuller and larger. I now thought it desirable to interfere more actively, and to ascertain the precise nature of the swelling; and, my patient having previously consulted Mr. Paget, who agreed with me upon the propriety of my doing so, I made an exploratory puncture with a hydrocele-trocar, and succeeded in bringing away in the cannula a small piece of cerebriform-looking tumour, which presented the general and microscopical characters of soft cancer.

I recommended the speedy removal of the tumour; and accordingly, three days after, I proceeded to the operation, in which I was ably assisted by my friends Mr. Lansdown, Dr. Marshall, and Mr. Corbould. I made an incision, and freely exposed a large white oval tumour, over which largely dilated veins ramified. The testicle was easily lifted from its bed, and the spermatic cord found just behind the external abdominal ring. It was held by Dr. Marshall with forceps, and I cut it through; it was very thick and enlarged, and covered with large dilated veins. The abdominal cavity was not at all exposed, nor was the peritoneum in any way injured. About nine ligatures were required; and of these, four or five were applied to the vessels of the cord. The wound healed for the most part by first intention, but continued to discharge from its extremities for about six weeks, at the end of which time my patient appeared quite well. His respite, however, was not long; for, in about nine months from the time of the operation, he began to suffer from symptoms which indicated a return of the disease in the lumbar glands. In these there gradually developed a large tumour, which, by its interference with the neighbouring organs, and especially with the stomach, caused a fatal termination in about sixteen months from the time of the operation.

There are three or four cases of cancer of the non-

descended testicle recorded; but it is a condition but rarely met with.

I have already said that I have not seen any case in which I could say life had been prolonged by an operation undertaken for the removal of soft cancer; but there are one or two cases recorded in which a cancerous testicle has been removed, and the disease has not returned; and if in any case such a result could be hoped for, it would be in such an organ as the testicle, where the disease remains for a long time enclosed within, and limited by, a dense capsule, and where, as was the case in the instance that I have just detailed, the disease was set up by an injury.

But, in these cases of soft cancer, we can promise our patient but very little. The bare possibility of his being one of the very uncommon instances of perfect recovery, some comfort, and the prospect of his being spared the loathsome ulceration of an external cancer,—this is all. In the other forms of cancer we can do more; because, even if the disease return, its natural duration makes the comfort and relief afforded by the operation better worth having; and this is specially the case in epithelioma. It is remarkable, however, even in this, the slowest of the carcinomatous diseases—so slow in its progress sometimes, and so little malignant, that one wonders whether it should be considered a cancer at all—cases every now and then occur which bring out its relation to the other cancers very clearly. Thus I had not long since a man under my care for a disease of the cheek, which presented all the general characters of epithelioma; but, upon microscopic examination of the tumour after its removal, it presented appearances so like those given by soft cancer, mixed with epithelioma, that I ventured to foretell a very early return of the disease; and, before the incision had healed, it did return, and spread with fearful rapidity.

SOUTH EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

CASES OF EMBRYOTOMY.

By JAMES V. BELL, M.D., Rochester.

[Read at Gravesend, March 30th, 1865.]

MRS. F., aged about 30, already the mother of three children, was expecting her fourth confinement in March. About five weeks ago, a soldier in the next house committed suicide by shooting himself; some circumstance connected with his funeral frightened her much. She said she was well up to that time; but far from it after. On January 28th, symptoms of labour commenced. The waters broke while she was getting into bed, but only slight occasional pains followed without any forcing efforts, during the whole of the two following days. On the morning of the 31st, about three o'clock, Mr. Steddy was sent for by the nurse, and tried to turn, but was unable. He regarded evisceration as the alternative, and sent for Mr. Fayle to assist him. Mr. Fayle was himself at a confinement, and sent the note on to me. I went at 10 A.M. and found the right arm of the child protruding through the ostium externum, and quite purple. On making examination, I found that with my right hand I could reach the head, which was situated anteriorly and posteriorly I could reach the angle of the scapula, but the uterine efforts caused by the introduction of the hand prevented anything further. I accordingly gave her three equal doses of tincture of opium amounting in all to half an ounce, at intervals of twenty to twenty-five minutes. Slight drowsiness was produced at the end of forty minutes, which increased in ten minutes after the third dose, and was attended with contrac-

tion of the pupils. I now endeavoured, first with my right hand, and then with my left, to reach the feet, but could not; the cramping influence of the uterus prevented my right hand from reaching beyond the left scapula, though with the left I could reach the buttock, but no further. The head was driven forward over the brim of the pelvis. It was now about half-past eleven; Mr. Fayle came in, and tried to turn, ineffectually.

Whatever might have been gained by waiting, if the child had been presumed to be alive, it could be of no use to delay any measures which could be employed safely for delivering the mother, now that the child was unquestionably dead. Therefore, with the sanction of Messrs. Fayle and Steddy, I resolved to perforate the thorax and eviscerate. This done, I hoped that there would have been room to secure the feet; but the uterus clasped its contents so tightly, that the hand was powerless against it; nor did there appear to be any appreciable advantage from the empty thorax and abdomen. There could be no objection to further spoliation of a dead child, so I took first a hernia-knife, and then a probe-pointed bistoury, and tried successively with these, introduced under shelter of the fingers of the left hand, to decapitate, by bringing the instruments to bear on the interval between two of the cervical vertebræ. As, however, the right hand also had to be introduced within the uterus, its power was rendered null and void; in fact, the bistoury was turned off the child's neck on to my sheltering thumb. I then be-thought me of the perforator; and in running it between two vertebræ and separating the blades; the head was severed from the body. The next pain brought the body into the world, and immediately succeeding the feet came the head. The drowsiness produced by the opium lasted more or less with intermissions during the rest of that day and the next; but no bad symptoms of any kind marred her recovery.

Another case which I had on February 26th, illustrates the good effect of not delaying embryotomy when it has to be performed.

Mrs. B., aged about 20, is a very small made woman of a very small made family. A sister of hers required craniotomy twice, and with her third pregnancy I brought on labour at the seventh month. Another sister, somewhat larger made, had had craniotomy for the first child, and the forep for one or two after. But this one was the smallest of the three. I went in the afternoon between three and four o'clock, and found the os uteri dilated, or rather quite dilatable; for it was kept from actually dilating by the bony conformation of the pelvis. The waters broke, and a large loop of cord came down under pressure of the head. I was unable to return it, and the questionable pulsation in it was soon without question non-existent. About eleven o'clock I tried the application of the long forceps. I could, with difficulty, introduce the very narrow blades by passing them obliquely into the outlet of the pelvis, but the completion of this application was very difficult, the pelvis being almost horizontally placed. I at last succeeded in locking them, and tried for about an hour exerting traction on the head, without any advance. I then sent for my partner, Mr. Fayle, that I might have the sanction of another for craniotomy, which I thought indispensable. He first tried traction with the forceps, but there was no advance. Accordingly about two o'clock A.M., I perforated in the sagittal suture, and, having broken up the brain and used the blunt hook, completed the delivery. My patient recovered without a bad symptom, except a slight feverish attack on the tenth day, which was only transitory.

Reviews and Notices.

LECTURES ON THE PATHOLOGY AND TREATMENT OF LATERAL AND OTHER FORMS OF CURVATURE OF THE SPINE. By WILLIAM ADAMS, F.R.C.S., Surgeon to the Royal Orthopædic and Great Northern Hospitals, etc. Illustrated by Five Lithograph Plates and Sixty-one Wood Engravings. Pp. 334. London: 1865.

THE eleven Lectures, of which this book consists, were delivered by Mr. ADAMS at the Grosvenor Place School of Medicine, in the Session 1860-61; and most of them have been since published in a contemporary.

The first Lecture begins with some Introductory and General Observations; in which the author states his reasons for delivering a course of lectures on Lateral Curvature of the Spine. He complains that there has been, in respect to this affection, a general deficiency of knowledge on the part of medical men, attributable to "the absence of any facilities in the Hospitals of this Metropolis for the clinical study of cases of spinal deformity." Hence our knowledge of the pathology and treatment of the disease is imperfect; and hence, too, the principles of treatment are opposite and antagonistic.

"A continuance of this state of things necessarily leaves open a very wide field to the pretensions of irregular practitioners. It cannot but be admitted, however, that the cause of the evil rests with the medical profession, and it is equally clear that we have the remedy in our own hands; but, so long as the pathology and principles of treatment of lateral curvature of the spine remain undetermined, we must never cease to be surprised that the public, who are never slow to discover the defects and uncertainties in medical practice, should believe—as one of the most able and scientific English authorities on spinal deformity, Mr. John Shaw, has observed—that 'these unprincipled practitioners have secrets for the management of distortions, with which surgeons are not acquainted'; and that the occasional success of the empiric, after failure under the direction of an eminent surgeon, by means diametrically opposite to those previously recommended, should 'confirm a parent's suspicion that the knowledge of the *quack* is superior in such cases, to that of the surgeon'." (Pp. 5-6.)

Mr. Adams then notices very briefly the so-called "systems" of treatment of distortion which have arisen out of empiricism; these being the systems of *complete recumbency*, *muscular exercises* or *gymnastics*, *cutting the spinal muscles*, *mechanical extension*, and *mechanical treatment* by means of spinal instruments. The last, Mr. Adams observes, forms, in conjunction with other means, the basis of modern orthopædic treatment.

He then goes on to refer to the improvement that is now taking place, and to the establishment of special hospitals for the treatment of distortions. On these institutions, Mr. Adams rightly observes, rests much responsibility.

"The profession generally will look to the surgeons of these special hospitals for such an extension of knowledge as careful investigation and practical experience will necessarily lead to, and they have also a right to demand their assistance in dispelling

the fallacies with which special branches of medical knowledge are invariably surrounded."

It is, Mr. Adams observes, the duty of the surgeons of these institutions to make them schools of instruction both to students and to the profession generally, and thus utilise them for the benefit of the poor of the country.

After an explanation of the object of the lectures, the remaining part of the chapter is occupied with a description of the healthy anatomy of the human spinal column. In the course of these remarks, when speaking of the normal—*anterior and posterior*—curves of the spine, Mr. Adams expresses his agreement with the opinion of Mr. Bishop, that the spine is weaker by being curved than it would be if it were straight; and that, in consequence, curvature in the mesial plane, as Mr. Bishop has observed, most commonly occurs at the sixth and seventh dorsal vertebræ, which are most distant from the vertical axis; and also that the weakness of the spine from curvature explains the prominence of the spinous processes of two or three lower dorsal vertebræ which is frequently observed in growing girls, but which, the author observes, is often a cause of unnecessary alarm.

Many anatomical writers speak of the existence of slight lateral curvature as a normal condition. Mr. Adams, however, founding his opinion mainly on observations made by him as demonstrator of morbid anatomy at St. Thomas's Hospital during twelve years, states any lateral deviation to be extremely rare; and in this opinion he agrees with Dr. Little. He says that he has known the belief that slight lateral curvature is a normal condition to be productive of mischievous consequences.

In the second lecture, the author speaks of the Physiology of the Spine in Relation to the Production of Lateral Curvature. He denies that there is any analogy between the articulations of the human spine and the joints of the limbs—such analogy being destroyed by the presence of the intervertebral cartilages; and consequently, he says, no analogy can be drawn between distortions of the spine and those of the limbs, such as some writers, Dr. Little especially, have endeavoured to trace. Mr. Adams fully discusses the physiological import of the oblique articulating processes, and of the ligaments and muscles of the spine. The theory, that unequal elongation and contraction of the ligaments produces lateral curvature, is denied by Mr. Adams, who adduces Mr. Skey's observations in support of his remarks. The muscles he considers as not being in a state of active tension when the spine is erect, but in a state of "vigilant repose"; and he holds that they do not act, primarily, in causing spinal distortion. But,

"As soon as the equilibrium of the spinal column is disturbed, and the body inclined to one side, the spinal muscles on the convexity of the curve are called into increased action and put violently on the stretch; they become tense and prominent, while the muscles in the concavity of the curve remain soft and flaccid. The latter circumstance appears to me to prove that the spine is *not* drawn into a curved posture by the active contraction of the muscles, in the same way that the arm or the leg is flexed when the biceps and hamstring muscles respectively become prominent and tense; but that the spine bends passively as a flexible column in consequence of disturb-

ance of its equilibrium, the result either of some alteration in the angle of its base of support—some tilting of the pelvis—or of some alteration in the distribution of the weight it has to support above." (P. 55.)

In the next page, he repeats that he has not been able to satisfy himself that morbid lateral curvature is ever produced by muscular action. He admits, however, that there is an apparent exception in wry-neck, which is produced by spastic contraction of the sterno-mastoid muscle; but even here, he says, the curvature "is a secondary and late effect of wry-neck, and depends as much on mechanical conditions as on physiological causes." The same reasoning, he says, is also applicable to the spinal curvature ultimately resulting from hysterical contraction of the scapular muscles.

In the third lecture, *Anterior and Posterior Curvatures of the Spine* are spoken of.

The fourth lecture contains an account of the External Characters and Morbid Anatomy of Lateral Curvature. In the fifth, the author continues his remarks on the Morbid Anatomy of Lateral Curvature, and speaks of the Changes undergone by the Bones and Cartilages, of the Deformity of the Chest and Pelvis, etc. In the sixth and seventh lectures, he discusses the General Pathology, Etiology, and Mode of Production, of Lateral Curvature; speaking also, in the seventh lecture, of the Symptoms. In the eighth lecture, he continues his remarks on the Symptoms, and also comments on the Complications and Natural History of the affection. The ninth lecture treats of Diagnosis and Prognosis; the tenth, of the Classification of Cases, and of the Principles and Various Symptoms of Treatment; and in the eleventh, the author describes in detail the Treatment which he believes best suited to the various forms of Lateral Curvature.

On all these points, Mr. Adams writes clearly and instructively. As an enlightened observer, he does not admit that any one class of causes produces spinal distortion, or that any one mode of treatment is equally applicable to all cases; but he points out how the disorder may arise from different sources, and how, accordingly, this or that remedy or combination of remedies is likely to be useful. Frequently, he expresses dissent from the opinions of his colleagues and of other authorities on various orthopædic matters; but there is no more than we must expect until the principles of the pathology and treatment of curvature of the spine are fully established. Towards fulfilling this desirable end, Mr. Adams has endeavoured to contribute his share; and we thank him for what he has done.

NOTES FOR STUDENTS IN CHEMISTRY; being a Syllabus of Chemistry and Practical Chemistry. By ALBERT J. BERNAYS. Fourth Edition. Pp. 92. London: 1865.

THIS little work contains a complete syllabus of the names, symbols, and properties of every important element and compound, organic and inorganic. The proof of the utility of the volume is shown by the fact that it has reached a fourth edition. Students, when reading for examinations, having no time to look up the larger manuals, are able readily to refresh their memories and find out their weak points by means of these Notes. Being quite unintelli-

gible to the mere tyro, the book does not dispense with handbooks for *learning* the science; and, differing from most of the minor manuals, it embraces the whole science of chemistry. A book which has already found such favour with the student scarcely requires recommendation from us. The merits of such a volume are shown by its success. Dr. BENNAY'S experience as a teacher has enabled him to give the student, in these Notes, just the aid which he requires for advancing or confirming his chemical knowledge.

British Medical Journal.

SATURDAY, MAY 13TH, 1865.

THE BRITISH PHARMACOPŒIA.

It is disappointing to find that a work promulgated with so much ceremony and at so great expense as the *British Pharmacopœia*, should have proved so unworthy a substitute for the works which it is meant to supersede. As a new edition is said to be forthcoming, we may perhaps usefully give a specimen of one or two of the most important errors in it.

As to the method of prescribing, it appears to us that the general discontent excited by the adoption of the new system of "grains" has a very solid foundation. It seems a somewhat arbitrary measure, that a small committee of physicians, assisted by some chemists and druggists, should alter the method of prescribing which has hitherto been adopted without inconvenience by the whole body of physicians. And all this innovation, causing considerable inconvenience to physicians, is introduced for no better purpose than to save the druggist a small arithmetical calculation in his operations. To this fault in the *British Pharmacopœia* may, we believe, in part be ascribed the neglect it has received at the hands of the great majority of English prescribers.

A more vulnerable point, because attended with greater danger, consists in various anomalies which disfigure its pages.

One of the most striking of these is the mistakes made in regard to the combination of chlorine with mercury, which have been lately especially noticed by Dr. Odling, in his lectures at the Royal College of Physicians.

In the *London Pharmacopœia*, the two combinations of mercury with chlorine were given as follows.

"Hydrargyri Chloridum (Calomelas, Ph. 1788)."

"Hydrargyri Bichloridum (Mercurius Corrosivus Sublimatus, Ph. 1746)."

In the *British Pharmacopœia*, they are given as follows.

"Calomelas.

"Hydrargyrum Corrosivum Sublimatum."

But in the *Materia Medica*, or first part of the

British Pharmacopœia, the first of these is called, "Hydrargyri Subchloridum, Hg² Cl"; the second, "Chloride of Mercury, Hg Cl." This alteration in the nomenclature of these important preparations, though supported by no less an authority than Gmelin, is now known to be incorrect. The most recent investigations of Dr. Frankland, of the Royal Institution, and of Dr. Odling, one of the most rising chemists of the day in London, gave the first chloride as Hg Cl, and the second as Hg Cl².

The verification of this view stands thus, as pointed out by Dr. Odling.

"Equal volumes of the volatile chlorides contain unequal volumes of chlorine.

"Calling the amount of chlorine in a standard volume of hydrochloric acid (i), the amount of chlorine in the same volume of calomel is (i); the amount of chlorine in the same volume of corrosive sublimate is (ii) 2; whilst the amount of chlorine in the same amount of antimony is (iii) 3, etc.; and so we have

H Cl	Hg Cl ²	Corrosive	As Cl ³
Hg Cl		Sublimate	Sb Cl ³

"The quantity of mercury which unites with twice 35.5 parts of chlorine to form corrosive sublimate, as with once 35.5 parts of chlorine to form calomel, has the same specific heat as

"An atom of silver, which forms Ag Cl;

"An atom of tellurium, which forms Te Cl²; and

"An atom of arsenic, which forms As Cl³.

"In corrosive sublimate, the chlorine is divisible into two parts; in arsenious chloride, it is divisible into three. Thus we have

"Chloramide, Hg Cl As;

"Iodoeyamide, Hg Cy I;

"Chlorethide, Hg Et Cl."

Calomel, therefore, as the *British Pharmacopœia* barbarously denominates this preparation, is a true chloride of mercury, and corrosive sublimate is a bichloride.

By this it is clear, that the *British Pharmacopœia* records an error in calling corrosive sublimate a chloride of mercury; but, putting aside the fact of this error, we must remark on the exceeding imprudence of giving a name which, by long custom, belongs to a harmless compound, to one which is as dangerous a poison as arsenic.

The excuse which will be made, that all who prescribe ought to adopt the new nomenclature, and prescribe strictly according to the *British Pharmacopœia*, will be no guarantee against accidents, because it is certain that many physicians will not abandon the custom they have always followed; and, again, many persons keep old prescriptions by them for years, continually getting them dispensed for use.

Hence, the "ignorance" which we observed in the reports of the discussions in the Medical Council to have been attributed to others, must in some degree attach to the authors as well as the critics of the *British Pharmacopœia*.

But, further, we are tempted to inquire how the Committee justify the use of the word "Calomel."

Setting aside the known prejudice of the non-medical public against the remedy, if prescribed under that name, we ask, Whence is the word derived? From the two Greek words, *καλος*, *good*, *μελας*, *black*. But, surely, this derivation cannot suit a word which is to designate a *white* powder! True, it has been hinted that the word "calomel" is of Arabic origin; but if such were the case, how is it that calomel in its genitive case, exactly follows that of the Greek word *μελας*, genitive *μελανος*.

It is evident, that the word is of Greek origin; and it was, in fact, introduced into medicine about two hundred years ago, and at that time represented the compound of sulphur with mercury, Hg S, Sulphide of Mercury, or Æthiops' Mineral, *which is a black powder*.

More than sixty years ago, the learned Dr. Turton, in his *Medical Glossary*, under the word "calomel", says, "I had hoped that the College of Physicians, in the appropriation of names to medicines, would not have neglected an absurdity like this."

Let us hope that, in the contemplated new edition of the *British Pharmacopœia*, the Committee may see fit to exclude the "absurdity" from the work.

In regard to the expense at which this new boon has been afforded to the medical world, we are at length able to state the authorised version of its cost, as printed by the Treasurers of the Medical Council.

The amount paid for compilation and printing	£6229	6	5
The receipts from sale, etc., to same date	5022	14	0

Leaving a balance against the Council, "due on account of publishing the *British Pharmacopœia*," of..... 1206 12 5
 With a stock in hand of 10,917 copies of the 32mo. edition—a stock not likely to be sold off on the eve of a new edition.

The *London Pharmacopœia* was produced at a cost to the Royal College of Physicians of, for each edition, little more than £200; of which £100 was presented to Mr. Phillips, the chemical authority of the College, and £100 to the editor of the work; and to each of the Committee, a small compliment in the form of a silver inkstand, they having declined other payment.

Every Fellow of the College received a copy of both editions (8vo. and 32mo.); and the funds of the College were increased by the sale of the work, on an average, by £50 annually.

"Look on this picture and on that!"

It is proposed that the new edition shall be of a size medium between 8vo. and 32mo. This form would save expense in paper, as compared with the very costly large edition; but a great want would still be felt by students, who cannot well do without a smaller and more portable, as well as a cheaper edition.

As a proof that smaller editions will be remunerative, we may mention that a large remaining number of unsaleable copies of the 8vo. edition of the *London Pharmacopœia* were rendered saleable by being cut down to a smaller size, for the especial use of students, and were all sold off; the ready sale proving the existence of the demand.

WHAT can legislation, Medical Councils, and the press do for our profession, while it insists on deliberately committing suicide? At another page will be found a short correspondence, which indicates descent, and contains a sad commentary on our professional *esprit*. The British Medical Association, and likewise the medical men of Reading, took active steps to obtain from the Postmaster-General the due remuneration of medical men for examination of lives under the Government Insurances and Annuities Act. That due remuneration would have been given, in accordance with their action, is certain, if members of the profession had not themselves interfered by offering to do the work at something approaching to the wages of a mechanic. The British Medical Association and the Reading gentlemen were met with the unanswerable remark, "We have offers by hundreds and hundreds from medical men, who are ready to do the work at 2s. 6d. per examination; nay, who beg and pray to be appointed on such terms." "And more than this," said Lord Stanley of Alderley; "here is the *Lancet*, which says 2s. 6d. is a 'sufficiently liberal' charge under the circumstances." How can we ever hope to see the status of our profession elevated, in the face of such telling facts as these? Nothing can be more manifest than that the Postmaster-General was ready and willing to have given a fitting remuneration, if the profession had demanded it. And who can blame a public official, if, in a free-trade age, he accepts the lowest tender from gentlemen whose fitness for the work to be done is guaranteed to him by the diplomas of Colleges and Halls?

OUR attention has been called to the fact—more eloquent than words, as indicative of the condition of the Navy Medical Service—that on the 8th inst. six surgeons were appointed to different ships, in lieu of assistant-surgeons.

"G. Bellamy, surgeon, additional, to the *Cumberland*; J. C. Eastcott, surgeon, additional, to the *Excellent*; W. Anderson, surgeon, additional, to the *Asia*; A. L. Archer, surgeon, additional, to the *Indus*; R. W. Beaumont, surgeon, additional, to the *Fisgard*; C. F. Godfrey, surgeon, additional, to the *Victory*."

These surgeons are appointed to do assistant-surgeons' duty; and for the manifest reason, that assistant-surgeons are not to be had at any price. This very important fact entirely supports the truth of a remark made in the rejected Report of the Com-

mittee appointed by the College of Physicians to inquire into the condition of the army and navy medical officers; viz., that the service, in respect of its supply of medical officers, has arrived at very much the same state which it was in previous to and during the Russian war. If there had been candidates for the navy medical service forthcoming, those surgeons would not have been appointed. Was the Committee wrong which asked the College to take cognisance of a state of things which has brought the service to such a pass? We may add, that we have had it as the undoubted opinion of one of the persons best fitted to know the facts of the matter, that, if another war were to break out to-morrow, the medical service of the army and navy would be found equally as unable to cope with the emergency as it was during the Russian war.

THE *Wien. Med. Woch.* says of the Czarewitsch's death:

"Professor Oppolzer has returned from Nice. On his arrival there, he found the imperial patient in a dying state. He remained an hour with him, and, after examination, pronounced his disease miliary tubercular meningitis, the result of chronic disease of the spine. He visited the patient with Karrel, Pirogoff, and Zdekauer. On the following day, and before the *post mortem* examination was made, the diagnosis was written down, and, at Pirogoff's request, witnessed by Princes Schuwaloff and Dolgorucki, and by General Adlerburg. This was done on account of a different diagnosis having been made, and because some of the Court were of a different opinion as to the nature of the disease. Pirogoff performed the *post mortem* examination; Oppolzer dictated; and Karrel wrote down the statement of appearances. On the *dura mater*, between the first and second lumbar vertebrae, was found a vascular fibrous tumour; and towards the *cauda equina*, several small tubercular granules. The second and third lumbar vertebrae were carious. A small abscess was found in the right *psaos* muscle; at the base of the brain, miliary tubercular inflammation and softening of the brain-substance; a large quantity of serum in the ventricles; and two obsolete cavities and several granules were found in the right lung. The left lung was sound. On the following day, after reading their report, the Emperor sent for Oppolzer, Pirogoff, and Zdekauer; and, in the presence of his whole family and of the Court, asked them whether, if they had been called in earlier, they could have saved his son; or whether the organic disease was incurable. To which they replied, that the case was hopeless. Thereupon the Emperor turned to his family and said: 'We must bow with humility and peace to the will of God.' The Emperor then thanked Oppolzer, and bid him remain another day in Nice, in order to examine the other imperial children; which he did, and declared them all to be free from tubercular disease, and in perfect health."

M. VELPEAU, in the name of M. Ollier, has presented to the Academy of Sciences a portion of a humerus twelve *centimètres* long, and comprising the superior articular head of the bone. This piece of bone had been taken from the arm of a young girl whose shoulder had been the seat of suppuration for several years.

The periosteum was preserved, and the bone had been reproduced. M. Velpeau showed photographs which proved that the arm could be moved in all directions; that there was no deformity; and that, therefore, the articular head of the bone had been restored. This fact, said M. Velpeau, proves the possibility of the reproduction of the bony epiphyses by the periosteum, and the error of those who maintain that such reproduction can only occur in cases of necrosis.

Professor Gilewsky of Krakau lately related to the Vienna Medical School a case of mucous polypus of the larynx in a young woman, which he had removed by dividing the thyroid cartilage. Very little bleeding followed. Professor Türeke said he was convinced that laryngotomy was in many cases the best operation for the removal of laryngeal polypi.

The Belgian Academy of Medicine have proposed the following subjects for their prizes—medals in value from 300 to 1,500 *francs*—for the years 1864 to 1866:—The History of Glycosuria; An Exposition of Scientific Medical Progress in the Learned Societies, etc., of Belgium; The Effects, etc., of Tobacco on Healthy Man; The Characters, etc., of Malignant Pustule, as observed in Animals—its Causes and Treatment; The Chemical History of Digitaline; The History of Van-Helmont's Medical Works, his Doctrines, etc.; The Treatment of Surgical Cancer; The Chemical, etc., Study of *Tenacetum Vulgare*; The Functions of the Parts of the Different Brain, as proved by Experiment, etc. The theses must be written in Latin, French, or Flemish.

In Vienna, during March, sixty-five dead bodies were brought under the inspection of the sanitary police—twenty-five more than in the preceding month. Of these, eleven were cases of suicide, four of accidents, and fifty in which the causes of death were unknown. *Post mortem* examinations of these are made.

Dr. Parkes speaks highly of Mr. Lowne's anemometer, constructed by Mr. Casella of Hatton Garden. It is similar to the instrument of M. Combes, but is much more delicate, is more easily read, and not so difficult of correction. Dr. Parkes thinks the instrument will be of great use in hospitals, mines, etc. By it, in two or three minutes, an observer can learn the amount of air passing into or out of a room; so that the state of ventilation of wards of a hospital may be readily and accurately determined.

M. Pelouze gives the French Academy his observations—the volumetrical analysis of the iron in the blood. Human blood, he finds, contains 51 *milligrammes* of iron in 100 *grammes*. Pig's and ox's blood contains from 48 to 50 *milligrammes*. In birds, the quantity of iron is much less. The blood of the duck contains 34, that of the goose 35, and that of the turkey 36 *milligrammes*.

EXCISION OF THE TONGUE BY MR. SYME.

On the 10th instant, Mr. Syme, in the presence of a very large audience, comprising a large number of practitioners, performed excision of the tongue. The patient, a woman of about 56 years of age, has been affected with malignant disease of the tongue for about two years. The affection implicated nearly the whole of the organ, extending to within a short distance of the hyoid bone. Having made an incision, dividing the skin in the median line from the lip downwards, Mr. Syme sawed through the lower jaw. The two portions being then held apart, he readily and rapidly dissected out the whole tongue. Only a few ligatures were required; and the patient lost but a very small quantity of blood. The wound was brought together by means of silver sutures. The whole operation lasted about twenty minutes. Before its commencement, the patient was kept under chloroform; the administration was, however, purposely not continued during its performance.

After its conclusion, Mr. Syme remarked that the operation for removal of the tongue might be said as yet to be an experiment, as there was uncertainty both as the immediate danger attending it and as to its ultimate success. Mr. Syme remarked that the patient upon whom he had operated six months ago, is still perfectly well, there having been no recurrence of the disease. He alluded to his not having continued the administration of chloroform during the operation, stating that his object was to prevent any passage of blood into the lungs, so as to keep them as free as possible from irritation. The patient, who bore the operation with remarkable fortitude, was able to walk out of the operating theatre, after its conclusion.

EXTRACTUM CARNIS LIEBIG.

At the last meeting of the Royal Medical and Chirurgical Society on Tuesday evening, specimens of this preparation, about which there is so much talk at present, were exhibited, and tasted by the Fellows of the Society. The specimens having been sent direct from Baron von Liebig to Professor Harley, there could be no doubt of their consisting of the genuine article. The substance is of a rich brown colour, and smells very strongly of osmazone—the fragrant principle of cooked meat. In consistence, it resembled very thick treacle; and one pound of it was said to correspond to the soluble matters of thirty pounds of ox-flesh. It was apparently very easily transformed into a savoury article of diet; for several of the gentlemen, after the meeting was over, took a teaspoonful, poured some boiling water over it, added a little pepper and salt, and there and then drank it off, with much apparent satisfaction. There can be little doubt that, if all the specimens are equally good with that exhibited to the Royal Medical and Chirurgical Society, the whole medical pro-

fession owe a deep debt of gratitude to Liebig for having put into their hands a means of giving to their patients the nutritive parts of animal food in a remarkably concentrated form. Professor Harley informs us that the preparation is extensively prescribed, both in hospital and private practice, in Germany; and is actually one of the remedies of the Bavarian Pharmacopœia, under the title of *Extractum Carnis Liebigii*. The specimens Liebig had sent him, however, were those just arrived from Uruguay, where they are prepared by the *Société de Fray-Bentos*. They were beautifully put up in white porcelain jars, which must have contained at least about a pound each.

THE HUNTERIAN SOCIETY: ADJOURNED DISCUSSION ON SYPHILIS.

THE next meeting of this Society is to be devoted to the discussion of a paper read by Mr. Hutchinson at a former one, on the "Medical Aspects of Syphilis." One adjourned meeting has already taken place; but the debate not being concluded, it has been decided to resume it next Wednesday, May 17th. The President invites the attendance of all interested in the subject.

No paper will be read; but the following propositions will be submitted to criticism.

1. Syphilis ought to rank as an exanthematic fever, having its stages of incubation, efflorescence, decline, and sequelæ.
2. The secondary rash (together with iritis, retinitis, condylomata, mucous patches, and superficial inflammations of the mucous membranes) is the exanthem stage.
3. Both primary and secondary stages will, after a certain duration, disappear spontaneously.
4. The evolution of the exanthem cannot be prevented by internal treatment during the period of incubation.
5. The symptoms which constitute the tertiary class are rather sequelæ (more or less accidental) than a true stage. They are irregular as to their time of outbreak, have no tendency to spontaneous cure, and they relapse over and over again after remedial treatment.
6. A very important distinction between the secondary and tertiary symptoms is found in the fact that secondary phenomena are, *as a rule*, symmetrical, and tertiary, *as a rule*, not so.
7. From the symmetry of secondary symptoms, we infer that they depend on a poison circulating in the blood; and from the non-symmetry of the tertiary, that they depend upon defective organisation of the solids rather than upon any free virus still existing in the blood.
8. This statement as to the non-symmetry of tertiary lesions applies only to acquired syphilis. In inherited syphilis some very remarkable differences are noticed. The distinction between the stages is much less marked, and most of the symptoms are symmetrical.
9. Of the symptoms which should be classed as tertiary, the following are the chief: deep or serpiginous ulcerations of the skin and mucous membranes; syphilitic orchitis; nodes, whether of bone, periosteum, cellular tissue, tendon, bursa, or ligament; deposits in the internal viscera, and diseases of the nervous system.
10. The investigations of recent observers have proved that very numerous and important organic diseases are remotely, but directly, consequent upon syphilis, and are to be cured only by proceeding on that supposition.

Progress of Medical Science.

ANATOMY, PHYSIOLOGY, & PATHOLOGY.

EPILEPTIFORM CONVULSIONS: EXTENSIVE HEMORRHAGE INTO THE RIGHT HEMISPHERE. At a meeting of the Pathological Society of London, on February 21st, 1865, Mr. Jabez Hogg showed the right hemisphere of the brain from a patient who died in epileptiform convulsions of thirty hours' duration. The subject of the case was a gentleman, aged 56, short, of full habit, and plethoric. One morning he was found insensible; his breathing was loud, but not stertorous; his pulse was quick, and a little blood flowed from the mouth. While Mr. Hogg, who had been called, was attending to the treatment of the patient, a violent epileptic convulsion seized him, which lasted quite ten minutes, when it subsided. The left side was paralysed. For from fifteen to twenty minutes, there occurred another seizure, and this was again succeeded by an interval of rest; other fits followed in tolerably regular succession. As near as could be ascertained twenty-five occurred in thirty hours. Towards the end they became weaker, but lasted longer; in the last fit he died. On opening the skull and removing the brain, a great quantity of clotted blood escaped from a wound in the right hemisphere, on a level with the section of the skull. The clots that thus escaped remained in the base of the skull, when the brain was taken; and as far as could be judged amounted to about three ounces of blood. The orifice from which the blood had escaped, communicated with a large cavity in the white substance of the hemisphere, extending from its anterior to its posterior extremity filled with clotted blood. The surface of this cavity was rugged, and both white and grey substance were completely broken down and mingled with blood. In this cavity there must have been two ounces of blood, so that altogether there could not have been less than five ounces. The small arteries of the pia mater were quite granular and in a state of fatty degeneration. This unusual amount of hemorrhage, Mr. Hogg considered, was probably due to the epileptic convulsions, which succeeded each other rapidly from the time of the first seizure till death (thirty hours after); some of them lasted as long as twenty minutes. The interest of this case hinges on the extensive destruction of brain-substance and the large amount of hemorrhage. It is a little remarkable in connection with this case, that the patient's relations never heard of his having had a fit at any former period of his life. However, during the summer of 1859, he lost the sight of the right eye by destructive internal inflammation, accompanied by much pain; and at that period he was treated for rheumatism, which extended down the right side of the body. Early in the following year, 1860, he placed himself under Mr. Hogg's care, and finding the sight of the left eye threatened, Mr. Hogg recommended enucleation of the right eyeball. This operation was performed; and the patient made a good recovery; the sight of the left improved, and remained perfect up to the time of the seizure just narrated. It is not improbable that the sight of the right eye was lost during a slight epileptic fit about this time. On examining the left retina, Mr. Hogg found many recent minute apoplectic spots distributed over it, but otherwise the eye was perfectly healthy. The mass which filled up the right orbit was wholly composed of fat and connective tissue;

and the optic nerve had become converted into a very thin but strong fibrous cord; not a trace of nerve-structure could be seen. Loss of speech took place simultaneously with the epileptic seizure. Consciousness certainly returned for a few minutes between the first and second fit, for he attempted to say something to Mr. Hogg, but was unable to articulate. This case was associated with hemiplegia of the left side of the body, and destruction of the right side of the brain. The left hemisphere was slightly congested, but nearly normal. The body was not further examined. Upon emptying the bladder with a catheter before death, the urine was found highly albuminous.

RUPTURE OF AN AORTIC VALVE. At a recent meeting of the Pathological Society, Dr. Wilks produced the very rare specimen of rupture of one of the aortic valves from injury. The subject, a young man, fell from a height on his side; he had lacerated his intestines, and died in three days from peritonitis. He had also great difficulty in breathing, but his heart was not examined during life. After death, one of the aortic valves was found torn from its edge to its base towards its side, as if it had been forcibly torn away from its attachment. Dr. Wilks supposed the rupture was caused by the extensive pressure of the blood on the valve produced by a sudden contraction of the aorta—there having been no direct injury to the chest.

SURGERY.

DISLOCATION OF THE CERVICAL VERTEBRÆ. Dr. Schuh of Vienna relates two cases of this accident, from which he deduces the following conclusions. 1. Although dislocation of an articular process produces but a slight twisting of the vertebral canal and contraction of the same, the accident is followed by disturbances of innervation. In both the patients, the upper limb on the side of the dislocation suffered. In one instance, that of a girl, there were pains proceeding along the course of the nerves arising from the cervical plexus. In the other patient, a man, there was congestion of the head and especially of the face; but the symptom was absent in the girl. 2. The results in the two cases appear to show that the functions of the spinal cord are not restored when reduction is effected with much force or only after repeated attempts; while, if replacement be easy, the disturbances of innervation are likely to disappear rapidly. 3. From the small number of cases recorded, it is not known whether, in the event of the dislocation not remaining reduced, the spinal cord and nerves may gradually accustom themselves to the pressure, so that the symptoms disappear; but Dr. Schuh does not think this occurrence probable. (*Wiener Med. Wochenschr.*, 4 Jan., 1865.)

TREATMENT OF GONORRHOEA. Dr. Thomas B. Henderson lately read a paper before the Glasgow Medical Society, on Two New Specific Remedies for Gonorrhœa. The first of the medicines is the oil of yellow sandal wood. It is obtained by distillation from the wood of the tree *Sirium myrtifolium*, of the genus *Santalum*. It grows in the East Indies. One pound of the wood yields two drachms of the oil. Lindley says: "This oil is said to be used to adulterate the oil of roses." Professor Redwood in his *Supplement to the Pharmacopœia*, on the authority of Dr. O'Shaughnessy, writes: "Sandal wood in powder is given by the native physicians in ardent remitting fevers. With milk it is also prescribed in gonorrhœa." Dr. Henderson has found sandal wood per-

fectly innocuous even in large doses. From twenty to forty minims three times a day, diluted with three parts of rectified spirit, and flavoured with cassia or cinnamon oil, is his ordinary formula. In cases of the disease at the first, second, or third stage, in susceptible persons, he has often seen the most marked suppression of the discharge within forty-eight hours. It is a pleasant medicine, not liable to cause sickness, agreeable to the taste, and grateful to the stomach. In Dr. Henderson's opinion, it is in efficacy equal, and frequently superior, to balsam of copaiba or cubeb pepper. He has used it in many cases during the past five years. The other remedy is the gurgun or gurgina balsam, or wood oil. It is the product of the *Dipterocarpus turbinatus*, an Indian tree. Wood oil is a liquid of the consistence of olive oil, of a dark reddish colour and slight odour. Pereira gives a good account of this medicine when speaking of the adulterations of balsam of copaiba. The description of this medicine which caused Dr. Henderson to try it is contained in Mr. Waring's *Manual of Practical Therapeutics*. It is now several years since Dr. Henderson commenced to experiment with wood oil. He has only used it in cases where copaiba had been fully tried and failed. In every case it was successful within a week. No symptoms of inconvenience in any of the cases were produced. It was given in doses of a teaspoonful two or three times a day, *uncombined*. It is not easily procured in this country. Dr. Henderson is thoroughly convinced that it is an excellent medicine. (*Glasgow Med. Jour.*, April 1865.)

COMPRESSION IN ANEURISM. In a Clinical Lecture on the Combination of Distal with Proximal Compression in Certain Cases of Aneurism. Mr. J. M. O'Ferrall, F.R.C.S., says that he has long since been of opinion that compression of an artery on the distal side of an aneurismal sac should precede or accompany that on the cardiac side of the aneurism. He has often observed arrest of pulsation easily accomplished, attended at the same time with a flaccid state of the sac; but in such cases, the moment the pressure ceased, the sac was filled and throbbled as before. The formation of the coagulum is thus desirable as the first step to consolidation. It therefore appeared advisable to interrupt the current only when the sac was full of blood. These considerations, together with the knowledge of the fact that ligation of the artery on the distal side has sometimes cured an aneurism when the upper or cardiac portion of the vessel could not be reached, led him to try this expedient whenever a fair amount of pressure was not followed by success. He thinks that cessation of pulse in a sac which suddenly diminishes in size and becomes flaccid is less likely to be followed by a permanent cure, whatever time may have been occupied in the compression; and that a sac which retains its volume, and is, moreover, full of coagulum, is less likely to be refilled, however short the duration of the compressing force. When the supply is completely cut off by ligation of the trunk, he believes that the danger of relapse from refilling of the sac by collateral sources is more likely to occur when the sac collapses and becomes flaccid at the moment of deligation, than when its dimensions are unchanged. This firmness of the parietes of the sac is always considered favourable to the success of the operation, as implying the presence of fibrinous deposits, whether we attribute them to stasis of the blood or to inflammatory exudation, as suggested by the researches of the late Dr. Abraham Colles. Mr. O'Ferrall has no doubt, however, that whether a sac be filled by fibrinous deposits of some duration, or by coagulum recently formed, a full sac is very influential in preventing

the ingress of blood from a compressed artery above, or collateral branches from below; the compression below the sac need not, in some cases, last more than a few minutes before the current above is stopped. If, on making the pressure above and arresting the pulsation the sac remains full, the object is attained, and time is merely required to allow the blood then liquid to coagulate in the sac. In other cases, it may be prudent to continue both compressions for a longer time. Three cases have already been treated on this plan with success. The first was published by Mr. O'Ferrall in the *Dublin Quarterly Journal* for November 1846. (*Dub. Med. Press*, March 1865.)

MIDWIFERY AND DISEASES OF WOMEN.

CONNECTIONS OF PUERPERAL FEVER. Dr. Barnes thus sums up the connection between puerperal fever and the local and constitutional conditions derived from pregnancy and labour. 1. Pregnancy induces a degraded condition of blood; throws an excessive burden upon the excreting apparatus; impedes the freedom of the circulation; causes hypertrophy of the heart. 2. Labour adds to the condition left by pregnancy; shock; extensive local injury; an enormous waste of nerve and muscle, the consequence of physical exertion; greater degradation of blood from this conversion of nerve and muscle, and also from the proceeds of the involution of the uterine tissues. 3. Hence a greatly exalted stress upon the excretory organs, and a general deterioration of the solids and fluids, inducing feeble physiological action, and therefore tendency to fall into pathological action; that is, to generate what in the strictest sense may be called puerperal fever.

EXOSTOSIS OF THE SACRUM: CÆSAREAN OPERATION. Dr. Marchant of Yvelles, relates the following case. J. L., from Vaux, aged 31 years, a tall meagre woman, of a strong constitution, had never been seriously ill before her marriage. She was married at 25, and had been four times pregnant. Her first pregnancy occurred in June 1859. Ten hours after labour had commenced, the head was found arrested in the brim of the pelvis; the os uteri being perfectly dilated. Three physicians declared that the sacro-vertebral protuberance somewhat narrowed the diameter of the antero-posterior portion of the superior passage and would retard the labour, which, however, would be effected by the natural efforts. Fifty hours after the commencement of labour, the woman gave birth to a well-formed child, that gave but feeble signs of life, and died. In 1860 she was again delivered, this time by craniotomy. After the extraction of the fetus, a hard bony tumour was found, with a broad basis, and united to the superior half of the sacrum. The transverse diameter of the superior passage having its normal width, the vertebral column showed no deviation. The woman again became *enceinte*. The bony tumour had grown, and increased the constriction of the sacro-pubic strait. She was again delivered by cephalotomy. In 1863, a fourth pregnancy occurred. The development of the tumour had reduced the antero-posterior diameter of the pelvis to five centimètres. This rendered embryotomy as dangerous as the Cæsaean operation, to which the woman resigned herself. She was subjected to an abundant bleeding, baths, a slender dietary, and purgatives, during the last eight days of her pregnancy. When the neck of the womb was effaced, Dr. Marchant proceeded with the operation. On opening the womb, the placenta was inverted. He disengaged it from the anterior part, and the child appeared at the opening through the breech. Hardly had he been extracted from the womb of his

mother, when he began most vigorously to utter his first screams. Having finished the operation by the extraction of the placenta and its appendages, and having carefully sponged the uterine and abdominal wounds, Dr. Marchant reunited the latter by means of the "uniting bandage." The woman had, twelve hours after the operation, violent acute pains, vomiting, pulsation frequent, and was bled to 250 grammes. Twenty-four hours after the operation: the pulse frequent; she had perspiration; the abdomen was painful, slightly swollen. Ten leeches were applied to the vulva; oily ointments were used. From the fourth day the inflammation declined; the abdominal wound began to cicatrise, and the patient recovered her strength. The child also, put out to nurse, was doing well. (*Dub. Med. Press.*)

MEDICINE.

INFLAMMATION AND VENESECTION. Dr. MacCormac of Belfast, says that, at one time, every case of inflammation was treated, without discrimination, by the lancet; and now, and for some time past, an effort is made, he must say equally indiscriminating, to treat every case of inflammation without the lancet. The type or types of inflammation, in his apprehension, are just what they always were. But, inflammatory attacks he does not think now so frequent as they once were. People clothe more warmly, and, thanks to machinery and the various mechanical aids, do not make such violent efforts. There cannot, he says, be any reasonable doubt that violent inflammatory action, in vigorous plethoric subjects, is lessened, often entirely quelled, by three, two, or sometimes even one copious detraction of blood. He who rejects bloodletting entirely, deprives himself of a most potent and often most valuable auxiliary. Some years since Dr. MacCormac was called in to see a gentleman with a feverish attack coupled with an inflammatory affection of the brain. Moved by the clamour against bloodletting, he resolved, most unwisely, to omit venesection. "You would not have done that at one period," said the general practitioner in charge, "you would have taken away thirty or forty ounces of blood from the arm." In due time coma ensued, and finally death. Perhaps the patient might not have recovered under any treatment.—M., a vigorous, robust, plethoric man of 60, was seized with pneumonia. There were great oppression of breathing, a full, hard, rapid pulse, great heat of surface, flushed face, high-coloured cheek bones, and tenacious rusty sputa. Dr. MacCormac leeches, blistered, opened the bowels moderately, gave cooling drinks, and antimonials. The result of this treatment was the loss of the patient.—R., a stout vigorous man, was very largely bled for pneumonia. The countenance, however, continued anxious, the breathing laboured, and the expectoration difficult, while the pulse continued 120. Dr. MacCormac bled no more, but gave mercury and opium every four hours. In twenty-four hours or so the gums were a little sore, profuse sweating came on, the pulse fell to 80, all oppression ceased, and the man did well.—A. was seized with pleurisy, consequent on a blast of cold air from the open hall door on first coming down stairs after her confinement. In the morning she was suffering much, restless, and had been meanwhile plied with hot brandy and water by her mother. Blood was drawn from the arm with much relief, and twelve leeches were applied. In twelve hours there was recrudescence, with great pain and fever. Dr. MacCormac again bled the patient, and then again, for the same reason, six hours later. He now put on a blister, and gave mercury and opium every three hours. In eight-and-forty hours,

there was copious sweating, the gums were a little tender, the pulse had fallen to 80, there was no pain or uneasiness, and the patient, after a severe, not to say formidable attack, in a short time was perfectly herself again.—B. A. was bled by another practitioner with much relief, for typhoid pneumonia. As the pulse was soft, with sweating and copious characteristic sputa, Dr. MacCormac proposed a grain of opium night and morning, and a bottle of port *per diem*. No case could end more favourably.—A young man was seized with ordinary brisk pleuritis. Dr. MacCormac bled him, put him in a warm bed, opened his bowels, then gave him a grain of opium every six hours. He was very rapidly convalescent.—A vigorous man of 76 was seized with acute pleurisy and fever. Dr. MacCormac bled him, put him to bed, and gave him full opiates night and morning, the bowels having been attended to. He did perfectly well, and was presently about again.—Having been hard worked, and greatly exposed during one of our cholera periods, Dr. MacCormac was seized with violent pleurisy in the left side. He could not breathe without great suffering, nor lie on the side. Growing rapidly worse, he sent for a medical friend, and made him take as much blood from the arm as he could bear. He then had applied locally four-and-twenty leeches; and, as soon as it could stick, a large blister, followed by a poultice. As soon as the bowels had been made right, he took full opiates. On the third day he got up after three days fasting. Dr. MacCormac believes that by giving up venesection, we merely tie up our own hands. Judiciously and carefully resorted to, it cuts short, or helps to cut short, inflammation, sparing the patient great suffering, great impairment of strength, loss of time, and the terrible sequelæ which are the very possible, and unhappily, too frequent results of unchecked inflammation. (*Dublin Medical Press*, March 1865.)

MUGWORT IN THE TREATMENT OF EPILEPSY. Dr. Joseph Edmundson, Medical Superintendent of the Lunatic Asylum, Clonmel, says that having had his attention called to an article written by Dr. O'Rourke, detailing his experience of mugwort in epilepsy, he selected from thirty-five epileptics three female and two male patients, and put them under treatment. The mugwort was procured from the Apothecaries' Hall, Dublin. The ale used was of the best quality, and the decoction was prepared by the apothecary of the establishment with scrupulous exactness, in conformity with the directions given in the article referred to. The medicine was administered in the prescribed quantities with unerring regularity. From December 10th the fits altogether ceased in one female case, which he hoped was the result of treatment, but they recurred again on January 24th, and have since continued with their accustomed frequency, and uninfluenced by the action of the mugwort. The male cases were selected with equal care, but as they did not, from reluctance on their part, take the medicine regularly, it would be unfair to record the result. Dr. Edmundson continued its use for fourteen weeks without producing the slightest effect. It is an admitted fact that a particular medicine may have a decided effect with one practitioner and fail with another. Dr. Edmundson believes that the recognised remedies for the treatment of epilepsy—zinc, iron, nitrate of silver, valerian, etc.—generally produce only temporary effects, lessening the violence and frequency of the attacks, or causing intermissions of greater or lesser duration. Hence the necessity of watching our cases to ensure that the mugwort is curative and permanent in its action, which time and close observation alone can test. (*Dub. Med. Press*, March 22nd.)

Association Intelligence.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
BATH AND BRISTOL. [Ordinary.]	York House, Bath.	Thursday, May 18, 7.15 P.M.
SOUTH MIDLAND. [Annual.]	George Hotel, Northampton.	Tuesday, June 6, 2 P.M.
NORTHERN. [Annual.]	Library, Newcastle-upon-Tyne Infirmary.	Wed., June 28, 10.30 A.M.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

The Council of Management hope that gentlemen will prepare papers and cases, and forward the titles of the same to Dr. Philipson not later than June 17th. Dinner at 6 P.M.

G. H. PHILIPSON, M.B., *Hon. Secretary.*

Special Correspondence.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

I HAVE recently seen a well marked example of that curious and interesting phenomenon called embolism, so often alluded to and described, but not commonly met with in a form that can be easily recognised during life. A man, aged 40, was admitted into the Northern Hospital, under Dr. Waters, in the advanced stage of phthisis. The right lung was extensively consolidated by tubercular deposition, with cavities; the left was also affected, but to a less extent. About a month after admission, he was seized suddenly in the night, with severe pain in the bend of the elbow extending down the forearm of the right side, with numbness and loss of power of the limb. The next morning, the arm was found to be nearly powerless; the temperature was diminished; and a total absence of pulsation in both radial and ulnar arteries. A small hardened, cord-like substance could be distinctly felt at the bend of the elbow, occupying the brachial artery immediately above its bifurcation; no doubt a plug of fibrine detached from some distant part of the vascular system, and completely obliterating the calibre of the vessel. The pain in the limb gradually diminished; the temperature varied, being sometimes higher and at others lower than the natural standard. Partial paralysis continued; but neither vesication, discoloration, nor any other indication of approaching gangrene appeared. In little more than a week, hemiplegia of the left side came on suddenly, followed by loss of consciousness, convulsions, and death. Unfortunately, a *post mortem* examination was not permitted; but the cause of death was evidently a further development of embolism, the obstruction on the last occasion, in all probability, occurring in one of the vessels of the brain. The patient was, in addition to his tubercular affection, the

subject of albuminuria; but careful examination and inquiry failed to elicit any evidence of disease of the heart or blood-vessels; so that the exact source of the embolus can be a matter of speculation only. One condition of which arterial emboli have been observed as a consequence is gangrenous phlebitis of the pulmonary veins or of pulmonary tissue, either or both of which, it may reasonably be inferred, might have existed in this case.

In the same ward, another case arrested my attention. A sailor, 47 years of age, who had lost his right arm eighteen years ago, was now under treatment for thoracic aneurism. The disease was at once apparent; indicated by a small prominent pulsating tumour in the right mammary region, which the patient had noticed for about six months, having complained of pain in the chest for some time previously. He had the peculiar ringing cough characteristic of the disease; but there were no general symptoms of great urgency or distress. He had been in the hospital three months. During that time, Dr. Waters had adopted the mode of treatment advocated by Dr. W. Roberts of Manchester, to which I alluded in a former letter (January 10th, 1863); viz., the continuous administration of iodide of potassium in large doses, commencing with five grains and increasing it to twenty grains three times a day. Under the observation of Dr. Roberts, this has, in some cases, been followed by very striking and beneficial effects upon the aneurismal tumour as well as upon the general symptoms; but, in the present instance, although the medicine had been pushed as far as the system would bear—namely, to doses of fifteen grains—and persevered with it steadily for several weeks, no perceptible benefit whatever seemed to result from its use. Another remedy—the application of ice to the tumour—appeared for a time to diminish the pulsation; but, after a trial of fifteen days, the relief afforded was so slight and so transient, that it was also discontinued, and the case remains much in the same condition as on admission.

In connexion with this subject, I may mention a case of abdominal aneurism in which very decided benefit followed the use of iodide of potassium; whether *propter* as well as *post hoc*, I must leave your readers to determine. A Welsh farmer, about 40 years of age, consulted me in June last for a pulsating tumour in the abdomen, which (he thought) had commenced suddenly a few weeks before, after a day of unusual bodily exertion accompanied by extreme mental anxiety. It was clearly an aneurism of considerable size. He returned home, became much worse, was confined to his bed, the tumour increased in size, the beating became much more perceptible, and, in the opinion of more than one surgeon who saw him, the case was likely to prove rapidly fatal. He was then, I believe by the advice of Dr. Waters of Chester, recommended to take the iodide; and, after persevering with it for many months, he presented himself to me a few days ago very much improved in every respect. He was able to walk a short distance without much difficulty. The sac had be-

come solidified to a considerable extent, and the impulse greatly lessened. I was much struck with the great improvement in his condition, both generally and locally; as I had anticipated a very different result when I first saw the case.

Reports of Societies.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 2ND, 1865.

J. C. LANGMORE, M.B., President, in the Chair.

Alcohol in Fever. Dr. C. DRYSDALE observed that the Society had hoped that this discussion should be opened by Dr. Hare; but, in his absence, he would endeavour to put together his own views on the administration of alcohol in fevers. Was this question to be decided entirely by experience? or was it not rather a question which ought also to be reasoned upon from our knowledge of the physiological effects of alcohol? The main difficulty in the experimental method of deciding this question was common to it with all other questions relating to therapeutics; viz., the extreme difficulty of tracing causation in medical inquiries. The profession were now becoming more and more alive to the little value of experimental statistics for deciding a question such as the value of alcohol in fevers, on account of the innumerable variety of combinations of circumstances which surround each case. This rendered it necessary that each case should stand on its own merits, and that the principles of treatment should be usually derived from a knowledge of the physiological properties of the ingesta and drugs used. With regard, then, to the physiological action of alcohol, the conclusions of Lallemand, Perrin, and Duroy, in Paris, which had been so well corroborated by Dr. Edward Smith, seemed to Dr. Drysdale to have clearly proved that the doctrine asserted by Liebig was untenable; viz., that alcohol was an excellent respiratory food; and that it was burnt in the body, like any other non-nitrogenous food. This account of the action of alcohol had, as was well known, long been accepted by the mass of physiologists, even by the most eminent, with a few exceptions, of which one was Dr. Carpenter, to whom very great credit was due for his maintaining the contradictory opinion against enormous odds. Dr. Parkes, in his work on the *Urine*, had said: "The belief that alcohol is very rapidly transformed into aldehyde in the blood (which, however, rests on no satisfactory analysis), and that this substance is then rapidly oxidised into acetic acid, oxalic acid, and carbonic acid, has obtained among the followers of Liebig general credence, and seemed to warrant the opinion that alcohol is a food, and that its combustion gives out an equivalent portion of heat. Arguments for the use of alcohol in health and disease have been based on this belief; and the late Dr. Todd in particular strongly urged the claims of alcohol to the rank not only of a stimulant, but of a valuable food." MM. Lallemand, Perrin, and Duroy had shown that alcohol is much more easily discoverable in the blood than has been said, and denied altogether its being changed in passing through the body. It was found in largest amount in the lungs, liver, and brain, after death. Dr. Edward Smith says that, "in adducing the necessity of alcohol in diseases to which it is suitable, I presume we are entitled to cite its action in health; for, whilst the degree of action in the former may differ from that in the latter, the direction is the

same." Dr. Smith also tells us that Lallemand, etc., have observed that, when a moderate dose of alcohol has been taken by a man or dog, the alcohol can be found in the expiration, the sweat, and the urine, for at least eight hours afterwards. The conclusions come to by the physiological experiments of Dr. Smith were: 1. Alcohol in moderate quantities excites the brain and raises the spirits. 2. The hands and face are reddened, and the heart's action is increased; the skin is dry and hot. 3. Alcohol yields a pleasant feeling of warmth in the stomach and alimentary canal. 4. It diminishes muscular force. 5. It is sometimes a diuretic. 6. It causes the breathing to become laboured and irregular. Such were a few of the data which Dr. Drysdale said he thought it necessary to be acquainted with, in order to enter, with hopes of arriving at any scientific conclusion, on the question of alcohol in fever. The consequences derivable from the experiments of Perrin, Edward Smith, etc., appeared to him to be, that we must abandon the theory that alcohol is a food, and henceforward use it as a valuable drug in certain cases. In passing, he might say that this view would, he had no doubt, greatly modify in future the habits of daily ingestion of considerable quantities of alcoholic fluids in health. His own experience was, that this was among all classes, but especially among the poor, a very grave error, leading to many fatal diseases; and there could be no doubt that medical men had been often deceived by the fascinating theories of Liebig. As to the use of alcohol in fevers, he thought the physician was to be guided by two great ends—1, to use it as a stimulant to the weakened stomach; and 2, as a stimulant to the nervous system, and, through it, to the failing heart. Thus, in the last stages of fever, when the body is much wasted, and is still becoming thinner, pure alcohol was indicated to sustain the heart's action and prevent metamorphosis. Wine, he believed, was a better form to administer alcohol than brandy; and eight or ten ounces of sherry in the twenty-four hours, or more of claret, mingled with the food, should be given frequently, in small quantities at a time. This, with fresh air, and plenty of milk and beef-tea, was, he thought, the best treatment of fever. He could not subscribe to the practice of some, who administered stimulants very largely, as much as twenty-four ounces in the twenty-four hours; and, although it was a matter difficult to be certain of, he thought he had more than once seen death follow this heroic practice, when it would not have supervened if less stimuli had been given. It must be remembered that young people under the age of sixteen did quite well in most cases with nourishment and nursing. Hence he believed the cases must indeed be rare, and he did not understand how we were able to detect them when they occurred, when such large quantities of brandy were at all necessary, as he had seen and read of as being administered by certain eminent physicians. Dr. Graves had said that he "fed fevers"; and this was a great advance over the bleeding and mercurialisation plan. But he thought over-stimulation was frequently almost as dangerous a practice as starvation; whilst the most successful plan was, he thought, that of feeding without much stimulants.

Mr. DE MÉRIC said he had not had much experience of his own; but he would mention that recently a little boy, his own son, had been taken with fever, with irregular pulse and failing action of the heart, and had been treated by Dr. West with large quantities of brandy; and he had been surprised at the large amount which the little patient had been able to take and be benefited by.

Dr. ANSTIE must say he disagreed with every pro-

position advanced by Dr. Drysdale. In the first place, he desired to correct a most erroneous impression which was prevalent with regard to the views held by the late lamented Dr. Todd. It was commonly believed and said that Dr. Todd, sustained by an extreme confidence in the views of Liebig as to the alimentary nature of alcohol, imagined that this remedy might be used to any extent with impunity, and that, accordingly, he did employ it in acute diseases, and more especially in fevers, *recklessly*. That last word, which had been so freely bandied about by the censors of Todd, filled him (Dr. Anstie) with amazement, not unminged with a sense of the ludicrous. For his own part, he had always considered that those practitioners were to be considered truly reckless who used any remedy, whether in large or in small doses, without having an accurate knowledge of the symptoms which indicated that the agent was producing specific poisonous effects. Dr. Todd's knowledge of these symptoms was profound; no one ever recognised with such tact and delicacy the first faint signs of any real oppression of the nervous system, any true alcoholic poisoning; and it was the habit of vigilant watchfulness for these symptoms which taught him the purely theoretical and untrustworthy character of the common ideas as to the action of alcohol indirectly increasing febrile excitement. At the present time, and indeed more or less ever since Dr. Todd's death, attempts had been made to revive the theories. It was commonly assumed in these arguments that Dr. Todd was indifferent to the production of intoxication in febrile diseases: and many of the assailants appeared to be ignorant of that extraordinary alteration in the reaction of the nervous system, under considerable doses of alcohol, which takes place in many acute diseases, and which Todd was the first to analyse in a really scientific manner. He was sorry to perceive that even so correct an observer in most respects as Dr. Gairdner appeared to be incapable of appreciating the immense importance of this consideration: the constant tendency of his arguments being to lay down stringent rules, as to the limitation of the quantity of alcohol to be administered in fevers, which in the presence of the real disease with its endless variations of type, in persons of about the same age and apparent strength, would be perfectly nugatory, and indeed very mischievous. Dr. Gairdner's observation about the less need of alcohol in the treatment of children than in that of adults, was true in a general and rough way; but it was one of those rules to which the exceptions are so important, that to persons of only moderate experience it might easily prove a most dangerous guide. A previous speaker (Mr. De Méric) had mentioned one pointed instance of the great value of alcohol in the case of a patient only 6 years old: and he (Dr. Anstie) must say that he had seen so large a number of such cases, although he admitted they were rather the exception than the rule, that he felt bound to protest strongly against Dr. Gairdner's wholesale statement. Another misrepresentation of Dr. Todd's views which had been frequently put forward, was the notice that he neglected to administer the substances ordinarily called foods in acute diseases and trusted entirely to the supposed alimentary virtue of alcohol; and that he did this because his whole system rested on Liebig's theory as to the transformation of alcohol. But, in the first place, Todd, so far from neglecting ordinary nourishment, was the most earnest inculcator of the necessity of constant feeding with beef-tea, milk, and such kinds of food; but he was accustomed to point out the fact that sometimes the appetite and the digestion of the patient will not allow us to make use, to any effective degree, of these aliments: and, that under these circumstances, the administration of any

considerable daily quantities of alcohol had a power to sustain life and nervous power, and to prevent extreme emaciation, which entitled it distinctly to the name of an aliment. But it was a great mistake to suppose that Dr. Todd considered Liebig's views as at all necessary to the support of his own. No doubt he inclined to Liebig's views, as did the majority of physiologists till quite recently; but he did not consider them of any essential consequence to the proof that his own estimate of alcohol, as an aliment specially suited to conditions of acute disease, was correct. The common idea was, that Dr. Todd believed alcohol necessary in every case of acute disease, especially of fever. Nothing could be more incorrect, as the old pupils of Todd knew full well. He was to the full as sensible of the varying characters of disease as any other observer, and would have repudiated any such generalising. But he had the sense to see also that, with regard to the use of alcohol in fevers, "quantity" is a word which has no meaning except a *relative* one. It matters not whether two ounces or twenty-four be the total quantity given in the twenty-four hours, provided that the rapidity of the pulse is seen to persistently diminish and its force to increase under the administration of successive doses; and at the same time there was an absence of the signs of intoxication. Every case must stand on its own merits. Dr. Drysdale had far too summarily disposed of the question of the present opinion of physiologists as to the action of alcohol. He (Dr. Anstie) had the strongest reason for doubting the justice of these conclusions arrived at by MM. Lallemand Perrin, Dr. Duroy, and Dr. Edward Smith. He had himself repeated with care the French experiments, and had added to them a number of observations of his own; and he was convinced that, so far as any accurate evidence can be obtained, the balance of proof was decidedly in favour of the opinion of M. Baudot, that only a minute surplussage of the alcohol ingested reappeared in an unchanged form, and that this waste portion amounted to a smaller or a greater part of the whole, just in proportion as intoxicative effects were or were not produced (including among these effects excessive action of excreting glands, which was a consequence of vaso-motor paralysis from the alcohol). And, besides all this, even if elimination, *en totalité et en nature*, had been proved, this would not satisfactorily demonstrate that alcohol was not a food. Water was so eliminated. And other, much more complex alimentary substances, which were ordinarily transformed in the organism, if administered untimely or in excess might be detected unchanged in the excretions. He (Dr. Anstie) considered, and he believed many sound physiologists agreed with him, that so far from this question being definitely settled it was only now commencing to be discussed in an adequate manner.

Dr. Cock thought it most important to define clearly what fevers were spoken of. In scarlet fever, for instance, with great heat and rapid pulse, if alcohol was given, no benefit was derived. In the active state of continued fever again it was not much indicated; but it is low state, and in the period of convalescence from continued fever that it is so markedly beneficial. He mentioned the case of a patient whom he had seen some time ago who remained in a very prostrate condition for a week, and for this took a bottle of brandy a day, at the end of the week variola broke out.

The PRESIDENT believed that a number of persons were under very foolish impressions with regard to Dr. Todd's practice in administering alcohols. He had heard it said, indeed, by some, that Dr. Todd's method killed more patients than it cured. Dr. Todd, he believed, only administered alcohol in such quan-

ties as each patient required. In diseases of a low type, such as diphtheria, large quantities may be given with great benefit; and he had known a patient in diphtheria do well with a pint of brandy in the twenty-four hours.

Dr. BROADBENT observed that, in the Fever Hospital, it was the custom to commence with alcohol from the earliest period of fever in all cases. The amount was measured by the appearance of the case, not by routine.

Mr. CURGENVEN said that some years ago, when clinical clerk to Dr. Brinton, that gentleman used to give brandy and beef-tea every hour in fevers; and this practice had appeared to him a very successful one. In one case, in a night-nurse, twenty-four ounces were administered in the twenty-four hours; and she recovered. At Scutari, too, the brandy and beef-tea system was found very useful. Six or eight ounces a day were given. Of late he had seen but little fever, as there was not much of it at the West End.

Mr. OWEN agreed with Dr. Drysdale in thinking that statistics were usually of but little importance in therapeutical inquiries. Sometimes, however, in an epidemic, a good deal might be learnt by watching the effects of different methods of treatment. Twenty-five years ago, he was student at Edinburgh; and at that time a grand experiment was going on on the administration of alcohol in fever. Dr. Alison represented, on the one hand, the stimulating school; and Dr. Graham was a partisan of the non-stimulating treatment of fevers. The result, however, of Dr. Alison's and Dr. Graham's cases was, that the same ratio of deaths occurred under both plans. Consequently he (Mr. Owen), on taking up a large Poor-law district in the country, did just nothing at all in fevers; and the consequence of this was, that his statistics were much better than those of either Dr. Alison or Dr. Graham. This he attributed to the better constitution of the country poor, and to the purer air in the country. He seldom gave alcohol, except in the later period of fevers; but he gave plenty of nourishment. In fine, he thought the non-stimulating plan the best for the country; but, in the deteriorated constitution of London residents, he had, from experience, found alcohol to be indicated in such cases occurring in towns.

ROYAL MANCHESTER INSTITUTION: MEDICAL SECTION.

WEDNESDAY, MARCH 1ST, 1865.

WILLIAM ROBERTS, M.D., in the Chair.

Clinical Thermometers. Dr. BOWMAN and Dr. WM. ROBERTS showed respectively the thermometers of Dr. Aitkin and Celsius for clinical purposes. Dr. Roberts preferred the latter as less fragile, more portable, and lower in price.

Pulverisation of Fluids. Dr. THORBURN showed Luer's instrument for the pulverisation of fluids, and suggested the use of Maw's little apparatus for diffusing scent in a room, as a cheap means of accomplishing the same end.

Bread. Dr. LEDWARD showed a specimen of bread prepared by McDougall's process, with phosphoric acid and carbonate of soda.

Post Partum Hemorrhage. Dr. THORBURN related a case of *post partum* hemorrhage from the rupture of an artery in the perineum. Mrs. D., aged 22, primipara, had a quick and easy labour, except that the external orifice offered considerable resistance, and there was a slight rent of the perineum. The placenta was expelled in a few minutes, and the

uterus contracted well. As the child did not respire freely, Dr. Thorburn's attention was directed to it for a short time; and the nurse, who had been directed to keep the hand on the uterus, came to assist him. After a few minutes, he noticed that the mother was very pale, and had all the symptoms of severe hemorrhage rapidly coming on. She was almost pulseless, and the bed was a sea of blood. Notwithstanding this syncopal state, the uterus was small and hard. He gave at once a large dose of ergot and brandy, with some laudanum, applied a cold wet cloth to the pubes, and grasped the uterus firmly. A vaginal examination with the other hand elicited nothing. On inspection, in order to ascertain the source of the hemorrhage, he noticed that it had a pulsatile character. This led to an examination of the perineum, where a tolerably large vessel was pumping freely. He seized the artery with a pair of forceps and twisted the bleeding end, when the hemorrhage ceased at once. The patient was a considerable time before she rallied; and Dr. Thorburn never saw a case of uterine hemorrhage more speedy and severe in its effects. She ultimately made a good recovery. He did not remember to have seen a similar case quoted, as occurring in consequence of parturition.

Pulmonary Consumption. Dr. THORBURN read a paper on the prognosis of pulmonary consumption considered in relation to its etiology. [It will appear as an original article in an early number.]

Correspondence.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ARMY MEDICAL OFFICERS.

SIR,—The medical profession has been surprised and pained by the very extraordinary conduct of the College of Physicians in the matter of the army medical service. On every side we hear astonishment and regret expressed.

I cannot but think that the gentlemen of the committee have just reason to complain of the discourtesy with which the College treated their report; but there is reason to fear that the result may exercise a very injurious effect on the officers whom the committee have laboured to benefit. The military authorities may say, with some amount of justice, "the best men of the profession have decided that the alleged grievances of the medical officers do not justify their interference," and we may fear the worst possible consequences. I see it stated in the JOURNAL, that "one gentleman who entered the army some forty-five years ago," ventured to express an opinion adverse to the committee. That gentleman cannot have a personal acquaintance with the present state of the service, and his opinion can have no real value. I am surprised that the College should have attached any importance to his statement. On looking over a list of Fellows of the College, I see the names of one or more army medical officers intimately connected with the governing bodies of the army. Of course, it it would be scarcely reasonable to expect them to have exerted themselves actively in the matter, as personal interest would prevent such gentlemen from condemning the conduct of military authorities; and common decency, I trust, prevented any "military" Fellow from actively opposing a movement for the advantage of the service to which he belongs, although he might not himself be in a position to feel the disadvantages which exist, or to derive any benefit from

justice being accorded. It must be recollected that there are few favoured officers who are not brought into contact with other classes of the army, and such gentlemen are not capable of giving a just opinion in the matter. Personal interest (if they are selfish men, indifferent to the honour of the profession) might tempt such to endeavour to earn the good will of the ruling powers, at the expense of their less fortunate brethren.

Although the College, as a body, have undoubtedly acted in an unworthy manner, the hearty thanks of the profession are due to the members of the committee who have so nobly exerted themselves for the honour of their brethren in the public services.

I am, etc., "ICHABOD."

THE GOVERNMENT INSURANCE ACT AND MEDICAL FEES.

SIR,—We shall feel obliged if you will give insertion to the enclosed correspondence, having reference to the remuneration of medical examiners to be appointed under the Government Insurances and Annuities Act.

We are, etc.,

T. L. WALFORD.
WM. BUTLER YOUNG.
FRANCIS WORKMAN.

Reading, March 11th, 1865.

SIR,—We beg to acknowledge the receipt of your letter, dated March 8th, having reference to the appointment of medical men to examine persons presenting themselves for examination under the Government Insurances and Annuities Act.

In reply, we beg to state that, some time ago, the medical men of Reading resolved not to accept a lower fee than half a guinea for the examination of a life from any insurance office. In the present case, bearing in mind the object of the above-mentioned Act, we are disposed to relax this resolution; and are willing to accept the sum of ten shillings as the fee for all examinations where the sum assured exceeds £50, and the sum of five shillings where it does not exceed that amount.

We shall feel obliged if you will bring the subject of the remuneration of the medical examiners again under the notice of the Postmaster-General, as we feel assured that, on a further consideration, his lordship will be satisfied that the amount which he proposes to recommend to the Commissioners of Her Majesty's Treasury is too small compared with the amount of time and labour required for each examination; the questions in the form which you have enclosed being more minute than those required by insurance offices generally.

We feel a greater confidence in asking for a more liberal remuneration, as the security against risk must depend upon the care with which the medical examination is made. Awaiting your reply,

We are, sir, your obedient servants,

T. L. WALFORD.
WM. BUTLER YOUNG.
FRANCIS WORKMAN.

F. J. Scudamore, Esq., General Post-Office, London.

General Post-Office, April 13th, 1865.

SIR,—In acknowledging the receipt of the letter signed by yourself and Messrs. Young and Workman, dated the 11th inst., I beg leave to inform you, that the subject of the fees to be paid for the examination of persons proposing to insure their lives under the Government Insurance Act was very fully considered by the Postmaster-General before the circular-letter, dated the 8th March last, was issued; and that the replies to that letter, expressing willing-

ness to undertake the duty for the terms proposed, have been so numerous as to render it unnecessary—at all events, for the present—to make any alteration in those terms.

The subject was again brought under the notice of the Postmaster-General by a deputation from the Parliamentary Committee of the British Medical Association on the 15th of March; but even at that early date after the issue of the circular-letter, the terms had been accepted so generally, that his lordship felt bound to inform the deputation that he could hold out no hope that the amount would be increased.

Since that date, the majority of the medical men to whom the circular-letter was addressed have accepted the terms; and applications are made daily to the department by other members of the profession for employment under the Act; in many cases, by more medical men than are required.

Looking, therefore, to all these circumstances, I can only express to you the regret of the Postmaster-General that he cannot entertain the application made in your former letter of the 11th March.

I am, sir, your most obedient servant,

FRANK J. SCUDAMORE.

T. L. Walford, Esq.

THE MYSTERIOUS POISONING CASE AT DAWLISH.

LETTER FROM W. B. HERAPATH, M.D., F.R.S.

SIR,—I have only just succeeded in obtaining samples of Simpson's rat-poison from Messrs. Blackwell and Son of Plymouth, who appear to be the only agents for this article in the West of England, as I have failed in getting it in most of the chief towns, even Exeter and Bristol; most of the druggists of whom I have inquired informing me that it is very seldom found in the trade. I have also analysed it, and find that the packets contain a very irregular quantity of material, varying from seven and a half to thirteen and a half grains. Four packets contained forty-one and a half grains, giving an average of a little more than ten grains for each powder, if all equally well mixed, and properly weighed or divided. The mixture consists of arsenious acid, potato-starch, coloured by smaltz, and flavoured and scented with some essential oil, probably oil of rhodium. I found ten grains of the well mixed powder to contain four grains of arsenious acid. It is, therefore, certain that Mrs. Williams had arsenious acid in her own possession; and that she must have taken from six to eight grains, as two empty packets were found by the police in her bedroom. This is a quantity sufficient to kill; but requiring more time, probably, than she liked. The explanation of the reason why the third packet was made use of has already been given.

I greatly regret that there was no opportunity given me of examining the saliva for strychnia, as that would have determined the question whether that poison had also been taken into the mouth. Mrs. Williams had been buried during the interval of the adjournment of the inquest; and I never saw the handkerchief.

It is probable, therefore, that Mrs. Williams purchased all these rat and vermin poisons at Plymouth, on her way up to Dawlish from Devonport; and the tracing of the arsenic into her own possession is satisfactory to all parties, as the matter is now fully explained, and all other theories must be for ever set at rest.

I am, etc.,

W. BIRD HERAPATH.

Bristol, May 10th, 1865.

NATURE AND TREATMENT OF FEVER.

LETTER FROM CHAS. MURCHISON, M.D.

SIR,—THE BRITISH MEDICAL JOURNAL for May 6th contains an excellent paper by Mr. A. B. Steele on the Nature and Treatment of Fever, one object of which is “to show that not only is there no specific for fever, but that, as Dr. Corrigan has observed, in the present state of our knowledge, there can be no specific for this disorder.”

I am much obliged to Mr. Steele for the flattering way in which he alludes to my work, and also for his criticisms on some of the doctrines enunciated therein. My object at present is not to defend those doctrines, nor to object to Mr. Steele's recommendations for treatment, with most of which I entirely concur. I wish only to correct one or two erroneous impressions of my views, which it appears to me, might be derived from a perusal of Mr. Steele's paper.

First, Mr. Steele remarks: “Like all *doctrinaires*, our author has his answer ready: ‘Typhus-poison’ (Murchison *On Fever*, p. 116), he tells us, ‘is some unknown compound of ammonia’; and, although he adds that it is perhaps premature or rash to hazard a conjecture as to its exact nature (p. 114), yet he founds upon this theory the use of mineral acids as neutralisers of ammonia in the blood. (P. 265.)”

Now, it is perfectly true that I have hazarded the “conjecture” that the typhus-poison may be some unknown compound of ammonia, and it is also true that I have stated that one object of treatment should be to “neutralise the poison and correct the morbid state of the blood”; but I think it will be apparent from the following passage, in which the acid treatment is spoken of, that its recommendation is based not so much upon any theory as to the nature of the typhus-poison, as upon my own experience and that of others.

“If the opinion be correct that the altered condition of the blood in typhus is due to the presence of ammonia, either derived from the original poison, or from the products of the destructive metamorphosis of tissue, the first of the above indications (*i. e.*, the neutralisation of the poison, and the correction of the morbid state of the blood) will be most readily fulfilled by the administration of mineral acids. But, whether acids act as antidotes, as alteratives of the blood, or as tonics, their beneficial effects in typhus are, in my opinion, undoubted; and it is curious to observe, that they have been recommended for this disease in all countries since the days of Forestus, Sydenham, Van Swieten, and Boerhaave. They have lately been highly praised by Huss of Stockholm; by Haller of Vienna; and by Drs. F. W. Mackenzie, Chambers, and Richardson, in our own country. . . . I have tried the mineral acids in many hundreds of cases during the last few years, and I believe them superior to any other method of treatment, although I am far from ascribing to them the wonderful virtues which some writers have done. . . . I have often observed marked improvement follow the commencement of the acid treatment, at whatever stage of the fever it was tried, and although no wine or brandy was given with it.” (Pp. 265-6.)

Secondly, although “to eliminate the poison and the products of the destructive metamorphosis of tissue” is another object of treatment laid down in my work, I condemn the incautious use of purgatives as strongly as Mr. Steele, as appears from the following passages: “The bad effects of excessive purging were exposed by Graves, Corrigan, and others; and the practice is now obsolete. Although regular action of the bowels is indispensable, I have repeatedly

known alarming prostration caused by diarrhoea, following the incautious administration of purgatives.” (P. 264.) “As already stated, however, active purging is to be avoided; and, in most cases, a small dose of castor oil, or a simple enema, is all that is required.” (P. 269.)

Lastly, the following passage from my work will suffice to show that, like Mr. Steele, I repudiate the idea of any specific cure for fever.

“In the treatment of typhus, medicines can do much to relieve symptoms, and to conduct the case to a favourable termination; but, as far as we yet know, they are powerless in arresting its progress, or in shortening its duration. Although many practitioners have at different times proposed to cut short an attack of typhus by such heroic remedies as blood-letting, the cold affusion, emetics, and quinine, we possess as yet no such specific. In an admirable essay, published in 1802, Dr. W. Brown of Edinburgh showed that the power of medicine in arresting or shortening typhus was extremely doubtful. Hildenbrand, in his day, observed: ‘No method yet known, whether rational or empirical, can cure the contagious typhus, either in a direct or an indirect manner, nor even abridge its ordinary and natural course, which is about fourteen days.’ In our own times, Dr. Stokes speaks equally strongly. ‘The treatment of fever,’ he says, ‘is reduced to a formula. We cannot cure fever. No man ever cured fever. It will cure itself. If you keep the patient till the fourteenth, the eighteenth, or the twenty-first day, he will recover.’” I am, etc.,

CHARLES MURCHISON.

79, Wimpole Street, London, W., May 6th, 1865.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on April 28th.

Barracough, Robert Wooding Sutton, Streatham Hill
Battison, John, Chesterfield
Birtwell, Henry Hargreaves, Blackburn
Clarke, Myrry, Jamaica
Corte, Arthur Armistead, Blackburn
Dod, Harry Davenport, Macclesfield
Ensor, John Arthur, Exeter
Fenn, Edward Liveing, Nayland, Suffolk
Flower, Frederick Isaac, Codford, Wilts
Gooding, Ralph, Ipswich
Hocken, Charles Edward, Chelsea
Humpbreds, Frederick William, Trinity Square, Tower Hill
Lattey, Walter, Clapham
Malim, George Warcup, Grantham
Rogerson, John, Bow
Tarleton, John Haigh, Birmingham
Taynton, William, Commercial Road
Wane, William Jeremiah, Lancaster
Watson, Alfred Marchmont, Peterborough

BIRTH.

BEDDOE. On April 26th, at 2, Lansdown Place, Clifton, the wife of *John Beddoe, M.D., of a son.

MARRIAGE.

WALKER—WALKER. On May 9th, at Wood Ditton, Cambridgeshire, by the Rev. Horatio Banks, D.D., *Thomas James Walker, M.D., of Peterborough, to Mary Elizabeth, second daughter of the Rev. J. Walker, vicar of Wood Ditton.

SIR DAVID DAVIES, M.D., died on the 10th inst. He received the honour of knighthood shortly after her Majesty's accession to the throne, was for many years the domestic physician of his late Majesty King William IV and Queen Adelaide.

A TESTIMONIAL is to be given to Dr. Jephson of Leamington by his friends and neighbours. Two hundred pounds have already been subscribed.

A NEW INFIRMARY. The Infirmary, called the Royal Albert, in course of construction at Bishop's Waltham, will, it is believed, be finished by the end of the summer.

PRESENTATIONS. Mr. James Lane has been presented with a timepiece, and Mr. E. H. Carter with a chronometer, by the patients of St. Mark's Hospital.

BEQUESTS. The late Earl of Ilchester has left by will £100 to the Dorset County Hospital at Dorchester, and the same sum to the Eye Infirmary at Weymouth.

ROYAL COLLEGE OF SURGEONS. Professor Ferguson will deliver six lectures on the progress of surgery during the present century, on Mondays, Wednesdays, and Fridays, at four o'clock, commencing on June 5th.

POISONOUS PRINCIPLE OF MUSHROOMS. MM. Sicard and Schoras have examined some poisonous mushrooms, and have succeeded in extracting an extremely poisonous substance, which appears to have basic chemical properties. The physiological effects seem to resemble those of curarine.

DINNER TO DR. HOFMANN. On the 28th ult., a number of gentlemen who have worked with Dr. Hofmann at the Royal College of Chemistry at different periods from its opening in 1845 to the present date, entertained the Professor at a farewell dinner immediately before his departure for Berlin. (*Chem. News*.)

THE ROYAL SOCIETY. The Council of the Royal Society recommend the following gentlemen for election:—Sir F. L. McClintock, Lieutenant-Colonel J. T. Walker, Dr. G. Harley, Dr. R. McDonnell, Rev. W. R. Dawes, and Messrs. H. Christy, J. Cockle, A. Geikie, G. Gore, R. Grant, G. R. Gray, W. Huggins, W. K. Parker, A. Tennyson, and G. H. K. Thwaites.

ATTEMPTED MURDER OF A MEDICAL MAN. The French journals give an account of a murderous attack on Dr. Lediberder by a hypochondriacal patient. The doctor was shot in the side and in the chest, but there are hopes of his recovery. The murderer attempted to kill himself, but failed in doing so.

WESTMINSTER HOSPITAL. The distribution of prizes to the students of the Westminster Hospital took place on Wednesday, May 10th; Lord Charles Russell in the chair. Mr. Henry Power, the Dean of the School, read a report on the condition of the Medical School, in which he spoke in the highest terms of the diligence and attention displayed by the students in the various classes, and alluded to the great success with which they had passed the several examinations before the examining boards. Lord Charles Russell then presented the several prizes to the following gentlemen. *Summer Session, 1864. Practical Chemistry*—Mr. W. C. Watson, prize (Macaulay's History of England); Mr. Joseph Oakman, certificate; Mr. John C. F. McDonald, certificate. *Materia Medica*—Mr. Robert C. Brookes, prize (Shakespeare's and Milton's Works); Mr. Arthur Hill, certificate. *Botany*—Mr. W. C. Watson, prize (Shakespeare's Works); Mr. Walter Moore, prize (Clarke's Shakespeare); Mr. Thos. J. Quicke, certificate. *Forensic Medicine*—Mr. G. P. Bate, prize (surgical instruments); Mr. Arthur Hill and Mr. Richard Bugden, certificates. *Midwifery*—Mr. R. Bugden, prize (surgical instruments).—*Winter Session, 1864-65. Anatomy*—Mr. J. C. F. McDonald, prize (Macaulay's History of England and Moore's Poems); Mr.

W. C. Watson, prize (Milton's Works); Mr. W. Moore and Mr. R. C. Brookes, certificates. *Prosector's Prizes*—Mr. G. P. Bate and Mr. R. C. Brookes. *Chemistry*—Mr. Winkworth, prize (Tennyson's Poems and Scott's Poems); Mr. Charles H. Furnivall, certificate. *Physiology*—Mr. J. C. F. McDonald, prize (Campbell's Poems and Longfellow's Poems); Mr. W. Moore, certificate. *Medicine*—Mr. G. P. Bate, prize (surgical instruments); Mr. R. Bugden (certificate). *Surgery*—Mr. G. P. Bate, prize (surgical instruments); Mr. Arthur Hill, certificate. *Clinical Medicine*—Mr. G. P. Bate, prize (surgical instruments). *Clinical Surgery*—Mr. G. P. Bate, prize (surgical instruments). *Dental Surgery*—Mr. J. Oakman, prize (dental instruments); Mr. R. C. Brookes, certificate. *Chadwick Prize*—Mr. G. P. Bate, prize (microscope); Mr. A. Hill, prize (case of midwifery instruments and surgeon's pocket case).

THE ROYAL ALBERT VETERINARY COLLEGE. A Company has been formed for the purpose of establishing in London a Veterinary College of the highest class. It is proposed to transfer to London the New Veterinary College of Edinburgh, now presided over by Professor John Gamgee, whose scientific attainments are well known. The Principal, Professor John Gamgee, will be assisted by his present colleagues in the New Veterinary College, Edinburgh—Mr. James Law, Professor of Anatomy; Mr. W. Duguid, Professor of Physiology; Mr. G. Armistage, Professor of Materia Medica; Dr. W. J. Russell, Professor of Chemistry; Mr. Joseph Gamgee, sen., Infirmary Superintendent and Professor of the Art of Farriery; and Mr. John Coleman, late Professor of Agriculture at the Agricultural College, Cirencester. A preliminary contract has been concluded for a site in the West End of London. The number of veterinary surgeons in the United Kingdom is very deficient, being less than in most parts of Europe. In the whole of Her Majesty's possessions there are not 1,500 veterinarians, whilst France has upwards of 3,000. The removal of the New Veterinary College from Edinburgh will be effected with as little delay as possible.

ODONTOLOGICAL SOCIETY. At the monthly meeting held on Monday, May 1st, the President, Thos. A. Rogers, Esq., referred to the recent death of Mr. Parkinson, the second President of the Society; and said he only echoed the sentiments of the whole profession in publicly recording the sorrow of their Society at the loss they had sustained. The Secretary brought forward a model taken in the practice of Mr. Walkinshaw, representing a case of torsion, in which the lateral on the left side was turned half round. On turning the tooth by means of the forceps, it was found to be of an oval shape transversely, so that it projected considerably beyond the natural arch. Some discussion ensued as to the use of the forceps for turning teeth; Mr. Tones and Mr. Catlin stating that they had frequently performed the operation with complete success. Models were also brought forward by Mr. Williams, representing cases of double cleft palate with double hare-lip, taken from children at the age of four, seven, and seventeen days. Mr. H. Rogers said he had been making experiments with a view to improve the quality of solders for the mouth. He tried several metals, but ultimately preferred cadmium, making the solder in the proportion of a grain and a quarter of cadmium to a dwt. of gold. That solder flowed easily, held well, and came a good colour out of the hydrochloric acid. Mr. Ramsay then read a paper on the Treatment of Congenital Cleft Palate adopted by Dr. Kingsley and himself. He proceeded to explain the method of producing the artificial velum, noticing the im-

provement which took place in mastication and deglutition after the fissure had been artificially closed. He also took up the subject of articulation, explaining the system he adopted in instructing the patient to articulate; and, lastly, compared Dr. Kingsley's method of mechanical treatment with the surgical operations which hitherto had been considered the most successful method for remedying those congenital deformities. A long and interesting discussion followed; and, at the close, the thanks of the Society were unanimously voted to Mr. Ramsay.

UNIVERSITY COLLEGE, LONDON. The Council has fixed Thursday, May 18th, for the examination for the Atkinson Morley Surgical Scholarship (£45 a year for three years). Mr. Henry Thompson has been appointed examiner in addition to the *ex officio* examiners, Professors Quain, Erichsen, and Wharton Jones; and Dr. Ringer has been named provisional examiner. On the 8th inst., Sir Rutherford Alcock, K.C.B., in the chair, the following prizes were awarded. *Practical Physiology and Histology: Silver Medal: R. Gowers. Certificates of Honour: George V. Poore, Thomas R. Loy, Gysbert H. Maasdorp, R. L. Roberts.—Anatomy: Senior Class: Gold Medal: G. H. Maasdorp. First Silver Medal: J. Wreford Langmore. Second Silver Medal: T. R. Loy. Certificates of Honour: Richard M. Pryce, Louis Le Grand, Thomas Lettis.—Junior Class: Silver Medal: W. H. Alchin. Certificates of Honour: David Havard, Samuel Pidwell, William J. Scott, Tempest Anderson.—Anatomy and Physiology: Gold Medal: William R. Gowers. First Silver Medal: J. Davis Thomas. Second Silver Medal: George V. Poore. Certificates of Honour: Louis Le Grand, Thomas Hopgood, J. W. Langmore, R. M. Pryce, Thomas B. Hay, Tempest Anderson, G. H. Maasdorp.—Chemistry: Gold Medal: Frederick Toplis. First Silver Medal: James John Bowey. Second Silver Medal: Tempest Anderson. Certificates of Honour: Temple A. Orme, Henry N. Martin, Henry James Benham, R. C. Joy, R. L. Roberts, Henry Cass, J. C. Bruce, Milward Harding, W. W. Houlder, A. Payton Hurlstone, Y. Yamaora.—Comparative Anatomy: Gold Medal: William H. Alchin. Certificates of Honour: Henry Cass, R. L. Roberts, Tempest Anderson, James C. Bruce.—Principles and Practice of Medicine: Gold Medal: J. Wickham Legg. First Silver Medal: William Hoffmeister. Second Silver Medal: Julian A. M. Evans. FRIDAY..... Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY.... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TO CORRESPONDENTS.

LIEBIG'S EXTRACT OF FLESH.—A correspondent writes: "You will greatly oblige if you can say where the 'extract of flesh' (as mentioned in last week's JOURNAL) can be had in London. [Perhaps some of our readers can answer the question. EDITOR.]

BRANDE'S DICTIONARY.—A second part of a very useful, and indeed much needed, work has just appeared, of *A Dictionary of Science, Literature, and Art*. By Dr. W. T. Brande, and the Rev. G. W. Cox. This second part takes us about half way through the letter C. We sincerely wish the work may prosper, and come to a successful termination.

MARY GREEN'S CASE.—(F. T.) Our own opinion of the case is, as it stands recorded, that Mr. Butler has been cruelly and shamefully slandered. We should be very glad to see those who circulated the slander called upon to substantiate its truth in a Court of Justice. We regret to add that, as is usual in cases where a medical brother is in distress, other medical brethren were found to come forward and assist in injuring him; and, of course, at the same time publish their own virtues to the world. If there were any real virtue in such displays, we should see its practical fruits, in some general provision made by the indignant public and profession, to meet such cases as that of Mary Green. It is very simple to be virtuous in words and to deal out sublime justice in print. The *Daily Telegraph*, who made itself conspicuous by its slanderous attack on Mr. Butler, occasionally gives us striking examples in this way. As our readers may remember, we some time ago alluded to a leader in that journal, wherein the atrocities of advertising quacks were strongly pointed out; and we remarked that the very journal in which the leader appeared, contained a number of the very advertisements which it was so roundly abusing!

THE CHEMISTS AND DRUGGISTS BILL.—SIR: One cannot but approve the motion to introduce the clause in the Chemists and Druggists Bill, to exclude all members of the Pharmaceutical Society from the practice of medicine; but ought not the Medical Council to be equally careful to prevent all medical practitioners from dispensing medicines over their own counters, a practice alike prejudicial to the interests of doctor and druggist? Might it not be made compulsory that no general practitioner dispense his own medicines when residing within three miles of a registered chemist and druggist, except in cases of emergency? Contrary to the opinion of some, I maintain the possibility of enforcing both these regulations, provided a recognised fine be attached to a transgression of the statute. Let every medical man communicate to the Central Council all cases evidencing counter practice that may come to his knowledge, the fact being duly substantiated by witness, and the report made within a month of the transaction. No general practitioner would have to wait long before some deluded patient would come confessing that he had had advice from Chemist So-and-so, had taken so much physic, and was no better: this would at once furnish a case in point. No druggist would hold out long against fines rigorously enforced, even if disposed to ignore the requirements of the Bill obtained for the protection of his own class. The case of a medical man continuing his own dispensing, without the necessity arising from distance, would soon become known, and could at once receive due pressure from the executive of our Medical Council.

I am, etc.

PERCY LESLIE, M.D.

Eastbourne, April 29th, 1865.

A Description

OF THE

MODE OF TREATING CONSTITUTIONAL SYPHILIS BY SYPHILISATION: AND ITS RESULTS.

BY

PROFESSOR W. BOECK, M.D.,
CHRISTIANIA.

IN the BRITISH MEDICAL JOURNAL of April 22nd, I see that Mr. Lee has replied to my two letters. My opponent being evidently a person desirous of advancing the cause of truth, I shall feel great pleasure in continuing the discussion opened in the JOURNAL, if space can kindly be given for my remarks.

Mr. Lee goes back to Ricord's theory of unity, and describes briefly the development of the theory of duality. He alludes, also, to the part taken by himself in elucidating this question; and touches subsequently on the method adopted by Dr. Bidentap to make the indurated sore suppurate, thereby producing a positive result by inoculation. But this positive result—the pustules produced by this method—has been represented by Mr. Lee as essentially different from that arrived at by inoculating from a soft chancre. Here it is that my observations and those of Mr. Lee diverge. This is the point from which we are led to such widely different views of the whole system of syphilology, and more especially of the process of syphilisation.

I will now, as briefly as possible, state my experience concerning syphilitic sores. As regards the common soft sores, we are, I believe, pretty nearly agreed. I will, therefore, pass on at once to those which are indurated, the infecting chancres. Of these there are a great number, differing but slightly one from the other. We have, however, two well defined forms.

1. One of these has a perfect resemblance to the soft chancre; but, a few days after its appearance, induration takes place in the base of the sore. It has no period of incubation, or only an incubation of two or three days, and is autoinoculable. This is the form alluded to by Ricord, when he speaks of induration never taking place earlier than the fourth day. It is the Hunterian chancre.

2. The other resembles the everted tarsal cartilage, with a period of incubation of from two to four weeks. It secretes a thinnish pus or only a serous humour, which it is difficult to inoculate upon the patient himself. Auzias Turenne was the first to describe this kind of chancre, and calls it *pseudo-chancere indurée*.

This other kind, which most people will, perhaps, be inclined to consider as the only true form of indurated chancre, is that which Mr. Lee has endeavoured to make inoculable by irritation; but he was only once able to produce pustules bearing any resemblance to the soft chancre. Dr. Bidentap has completed a series of such inoculations, and has arrived at quite a different result from Mr. Lee. He has found that by far the greatest number of indurated chancres, when irritated in different ways, can be readily inoculated in the patient who has them,

and that a pustule is formed producing a sore exactly similar to those which follow inoculation from a soft chancre. Dr. Bidentap has described the results he has arrived at in a paper entitled "On the Syphilitic Virus." Of the different cases described in this pamphlet, you will permit me to bring forward two.

The patients were under treatment in the hospital of Christiania for infecting chancre; and on being inoculated daily in the sides, the secretion seemed at first to be attended with a negative result; but after a period of incubation, lasting from a fortnight to three weeks, papules made their appearance, which, judging from the description given, must have closely resembled those produced by artificial inoculation with matter from tubercula mucosa on healthy persons—with this exception, however, that induration in these cases did not take place. On the other hand, indolent buboes appeared along the edge of the pectoralis major after the formation of papules, precisely as would have been the case if the person had not been suffering from syphilis. After the chancres had been made to suppurate by means of irritation, the inoculations were attended with another result. A characteristic syphilitic pustule made its appearance without any previous incubation, leaving behind it a soft ulceration exactly similar to the non-infecting chancre. I will add that one of these patients was taken to my ward of the hospital, and that I from day to day carefully watched the inoculations.

Whilst Dr. Bidentap was making his experiments in this city, Dr. Melchior Robert of Marseilles commenced a series of similar experiments, and arrived at precisely the same result as Dr. Bidentap, neither of these gentlemen having had the slightest knowledge of each other's experiments until after their publication, which took place simultaneously.

After what I have stated, it will be seen that there are indurated chancres which can be inoculated without difficulty; that the result of such an inoculation is a pustule and a sore, having a perfect resemblance to the soft chancre-pustule and sore. Similar pustules and sores can also be generated from the indurated chancres which pass through the long period of incubation, if they have been previously made to suppurate. But, says Mr. Lee, "If this process be necessary in order to obtain an inoculable secretion, it is evident that it is not the natural action alone which is inoculated. It is the adventitious artificial action which is propagated; and we must inquire how far the original disease is modified or altered by this process." This objection of Mr. Lee it is hardly necessary to refute, as I have shown that there are indurated chancres which do not pass through a period of incubation, but can, notwithstanding, be inoculated in a similar manner to soft chancres; but as Mr. Lee's objection stands there, I may as well answer it.

Mr. Lee is quite right in asserting that a sore when irritated, even if it be not a syphilitic one, can secrete an inoculable pus; but he will surely be prepared to admit with me, that the pustule originating in this manner cannot be inoculated again and propagated through a long series of inoculations. Whenever this is the case, it may be considered as an undoubted proof of the sore being syphilitic; and it is, indeed, solely owing to this lasting inoculability of the pus, that I have been able to make use of it for syphilisation.

The case is quite different when matter from a soft chancre is introduced into the surface of an indurated one—an experiment I have frequently tried. By this means, too, the sore becomes irritated; but the pus here introduced is specific, and this cannot, therefore, be compared to the common irritation.

Mr. Lee having alluded to the experiments made by Dr. Danielssen and myself, with matter taken from indurated chancres, on persons who had never suffered from syphilis, I will, in the first place, repeat what I have emphatically stated on other occasions, that syphilisation ought never to be practised on healthy persons; and I quite agree with Mr. Lee, that a high degree of culpability attaches to such an act. I have never practised syphilisation once on persons not suffering from syphilis, excepting in cases which were altogether hopeless. The patient with eczema on whom I tried it, was a girl who had been in the hospital for upwards of ten years, suffering from an universal and most painful eczema. With despair she saw that every remedy employed was of no avail; and was, on the other hand, witness to the fact, that all who underwent the process of syphilisation for syphilis were not only cured of this disease, but enjoyed excellent health. She, therefore, of her own free will, earnestly requested that she might be syphilised. At last, I yielded to her continued solicitations, giving her clearly to understand, that I was by no means sure she would receive any benefit from the treatment.

Though this declaration has nothing to do with the matter in hand, and is consequently out of place here, I am unable to resist the temptation of making it, lest English readers should erroneously suppose I have ever, in a single instance, unjustifiably practised syphilisation.

When the theories of unity and duality had been more clearly defined, I thought the above mentioned patient, who had been inoculated to immunity with matter from soft chancres, a fit subject on whom to try whether matter originating from an indurated chancre would have the same effect as on persons not previously syphilised, which it must have had if its nature be essentially different to that of the matter in soft chancres. Mr. Lee has shown us the result of the inoculation: the sores did not indurate, and it was not possible to propagate the action by a series of inoculations, there being already immunity; and not, as Mr. Lee seems to imagine, because this matter had not sufficient intensity to produce a stronger effect on any other person.

Mr. Lee then alludes to Dr. Danielssen's case; and it must be confessed that, to persons not familiar with syphilisation, it sounds strange. I do not, however, for a moment intend taking refuge in the supposition that the observations of my colleague are wanting in accuracy; for Dr. Danielssen is a keen observer, and a thoroughly reliable author. I will simply state that Dr. Danielssen was not then, and is not now, a dualist, but a unicist; he has said so himself in the treatise where the history of the above mentioned case will be found. Of this Mr. Lee was not aware; but several persons, who have also alluded to the case, knew it perfectly well, though they have passed it by in silence.

From the continuation of Mr. Lee's remarks, it appears he is of opinion that the matter which I use in syphilising does not produce pustules and ulcerations similar to those which follow inoculation with matter from soft chancres; but as regards this he is quite mistaken, their form, extent, etc., being precisely the same.

I will now pass on to the conclusions which Mr. Lee arrives at, and will cite, for such of your readers who are not so familiar with this subject, Mr. Lee's own words.

"It thus appears that three very different actions have been included under the term syphilisation; and, until these actions are distinguished, the confusion which has hitherto reigned with regard to this subject will continue.

"1. There is the inoculation of real syphilis in a constitution not previously affected.

"2. The inoculation of the secretion of the soft or suppurative sore.

"3. The inoculation of the accidental or artificial suppurative action induced upon an indurated sore."

From what I have already stated, there can be no question whatever about the first of these points. From the very moment I commenced practising syphilisation, I laid it down as an invariable rule never to inoculate healthy subjects, nor those suffering from primary syphilis. But, on the other hand, when every drop of blood in the system has become imbued with the syphilitic dyscrasy, no harm can possibly arise from inoculating the skin with the syphilitic matter.

Now to the second point—inoculation with matter taken from a soft chancre. Mr. Lee adduces here what has been said of the syphilisations practised with this matter in Vienna. To this I am able to give a definite answer, having for several years used indiscriminately matter from soft and from indurated chancres.

After inoculation with matter taken from a soft chancre, immunity invariably results: it is a rule without exception. With regard to the phagedenic sores which are said to follow these inoculations, they will never make their appearance if attention be paid to the rules I have given for selecting the spot to be inoculated. Mr. Lee must not, therefore, judge of this process by its results as practised in Vienna. He, and whoever wishes to form a just opinion of the merits of syphilisation, must be prepared to pay a visit to our little city of Christiania; and I feel confident that Mr. Lee would then no longer say "the anticipated result—complete failure to cure syphilis, as to prevent its recurrence"—was all he had seen of my treatment. Mr. Lee even believes my records to be accurate; but, when I bring forward from seven to eight hundred cases in which syphilisation has been signally successful, and not a single one in which danger resulted in consequence of the treatment, he is still sceptical, and points to a few cases in Vienna in which the treatment failed to have the desired effect. The only logical conclusion to be arrived at here would seem to me to be this, that syphilisation was not practised in Vienna as it should be; for I have before called attention to the fact that it has been considered unnecessary to follow strictly any particular directions, erroneously supposing that syphilisation consisted in inoculating a few times at unfixed intervals; and if the patient—which was not to be wondered at—grew worse instead of better, the whole theory of syphilisation was cried down as a chimera, and its adherents, to use the mildest expression, as enthusiasts. What, may I ask, would be said of a physician who should prescribe quinine in an equally arbitrary manner for intermittent fever, and then exclaim, on seeing his patient grow rapidly worse, "It is mere folly to prescribe quinine for intermittent fever"?

I now arrive at the third point. Mr. Lee is of the opinion that inoculation with matter taken from indurated chancres is not attended with danger; but this is because he imagines the result of these inoculations to be different from that which follows inoculating with matter taken from soft chancres. When Mr. Lee learns that the inoculated matter from indurated chancres produces pustules and sores precisely similar to those generated by matter taken from soft chancres, we shall, I fear, be no longer agreed on the innocuousness in its application. Hundreds of cases have, however, convinced me that these inoculations have no pernicious effect whatever, but are, on the contrary, the best remedy for syphilis.

To be sure, Mr. Lee considers the results of my syphilisations on children suffering from hereditary syphilis beyond all measure bad, asserting that, in England, they are without a parallel. This statement surprises me, familiar as I am with hereditary syphilis in our country. In my work entitled *Recherches sur la Syphilis*, page 504, I have made mention of 104 children, all of whose mothers, with the exception of one, had been treated with mercury for constitutional syphilis. Of these 104 children, sixty-two died, none of them having been syphilised. This is, consequently, a still worse result; and yet I was under the impression that it was not of the worst. My statistics are certainly not based on an imposing array of figures. They have, however, the advantage of including every case of hereditary syphilis in children brought to our hospital in Christiania for this disease; and their accuracy I can vouch for. I should be glad if Mr. Lee would give similar statistics from England. We should then be able to institute a comparison.

In order to throw as much light on this question as lies in my power, I will now cite a part of what has been said by the latest writers on this subject. In Acton's *Practical Treatise on Diseases of the Urinary and Generative Organs*, page 645, we read: "Fatal cases of syphilis in children are much more common in the metropolis than the profession is aware of." He then gives a table of over 203 children who died of hereditary syphilis in London in the years 1846-1848, in order to show at what ages this disease is most fatal to children. Trousseau says, in a clinical lecture delivered in 1858: "If hereditary syphilis make its appearance a few days after birth, it may be considered as incurable; if there are no symptoms before the second or third month, good hopes may be entertained of effecting a cure, provided the wet-nurse be healthy."

This statement of Trousseau is quite correct, and may be transposed thus. In the first-born children, the dyscrasy breaks out at the earliest period of their lives; in those born later, the disease seldom makes its appearance until after the lapse of a couple of months. In those born first, the internal organs are, as a rule, found to be attacked; in those born later, the disease generally breaks out on the skin and mucous membranes. The children I have syphilised have been taken in treatment indiscriminately, as brought to the hospital, without regard to their symptoms, wishing to see how far syphilisation could be carried.

Pottou relates that, according to the statement of Girard, who practised in the Department of Isère, where numbers of children from Lyons are put out to nurse, syphilis was fatal in two-thirds of the children infected with it. (Rosen, *On the Offspring of Syphilitic Parents*, Copenhagen, 1859.) Zeissel says: "As I have already observed when treating of the different forms of syphilis on the skin, I consider congenital syphilis as an invariably fatal disease." I must, however, remark that Zeissel, by the word congenital, means symptoms of syphilis existing at the birth of the child.

This may be as it will: my experience of the treatment of hereditary syphilis justifies me in continuing to practise syphilisation also in this form of the disease.

Mr. Lee returns to our mutual patient, and says: "... but I cannot conceive it possible that in the case in question, seen by so many eminent men, a disease could have been acquired which remained dormant, without giving any signs of its existence, during a period of six years, and then for the first time showed itself with such terrible severity. Such a case, if substantiated, would, I believe, be unique

in the annals of medical science." In a former number of the JOURNAL, I have stated the results of my own experience on this point, but prefer, instead of laying stress thereon, to cite what Ricord, in his *Lettres sur la Syphilis*, says on the subject: "Il n'y a pas de praticiens qui n'aient vu des malades qui, après avoir été traités, ont joui pendant dix, quinze, vingt, trente ans, de tous les privilèges d'une excellente santé, et qui ont fini par présenter, soit pour la première fois, soit comme récidive, des accidents caractéristiques de la syphilis. En présence de faits de ce genre, malheureusement si nombreux," etc.

Mr. Lee and I disagree on many points; but, should the proposal made in my last letter be accepted, I should be glad if Mr. Lee were selected to watch my mode of treatment, being convinced from his correspondence that he is a man who has the cause of truth at heart.

AMERICAN ARMY HOSPITALS. One hundred and eighty-two hospitals, with a capacity of 84,472 beds, were in operation at the date of the last annual report. During the summer campaign it was found necessary to establish additional ones, and increase the capacity of those nearest the scenes of active operations, giving a capacity of 125,521 beds in June 1864.

LUNATIC PAUPERS. Dr. Stiff, superintendent of the Nottingham Lunatic Asylum, in his last annual report, calls attention to a matter of some importance in connection with the admission of lunatics into an asylum, which should be more generally known than it appears to be at present. In the case of ordinary paupers, the proceeding is to take the alleged lunatic before a justice or an officiating clergyman, who, after calling in a medical practitioner, may grant the order of admission. A different procedure must be adopted in the case of persons who are not chargeable to a union but who are alleged to be dangerous lunatics, and not under proper care and control. The person deemed to be lunatic must be brought *before two justices*, by whom the case is to be dealt with, after a preliminary examination of one justice with the aid, if necessary, of a medical man, and if the two justices be satisfied, and the physician or surgeon sign a certificate that such person, not being a pauper, is insane, they may direct him to be received into an asylum. It is to be feared that persons not being maintained out of the poor-rate, are sometimes brought before an officiating clergyman of the parish, and committed to the asylum. The inconveniences attending this practice are, that persons, whose circumstances have not been inquired into are thrown upon the county rate without magisterial authority; that no opportunity is given to the friends to come forward and take charge of them, and that in case of any legal inquiry into the settlement of the individual being made, the original order of admission would be quashed. That due care and judgment must be exercised is shown by the Islington case, where an alleged lunatic, not legally chargeable, was removed to the workhouse, under the direction of the relieving officer, against whom an action was brought. The jury found a verdict for the plaintiff, and the damages and costs, on both sides, amounted ultimately to nearly £900. In another case recently tried, £20 damages were obtained against a relieving officer, for causing a person not maintained out of the poor-rate to be placed in a cab and lodged in the lunatic ward of the workhouse. The judge decided that, although the defendant had simply acted as he believed it to be his duty to do, yet he was legally wrong in not observing the statute.

Original Communications.

ENTOPTICS:

OBSERVATIONS ON THE RELATIVELY GREATER FREQUENCY OF MYODESOPSIA IN THE MYOPIC EYE.

By JABEZ HOGG, Esq., Assistant-Surgeon to the Royal Westminster Ophthalmic Hospital, etc.

On the continent and in this country, entoptical observations have received a considerable share of attention from men of science both in and out of the profession. The increased care with which the internal eye has been studied since the introduction of that invaluable instrument the ophthalmoscope, has led to a far better explanation, and a fuller appreciation of the value of such inquiries.

Myodesopsia, whether investigated by the philosopher purely in its relation to optical phenomena, or by the medical man as a symptom of some value in the treatment of certain derangements of vision, is, I venture to say, of sufficient importance to warrant a careful record of such facts as may from time to time fall under the observation of the ophthalmologist.

It is well known to most practitioners, that few symptoms in connection with derangement of vision prove more alarming to persons of a nervous temperament than the constantly recurring *muscæ volitantes*;^{*} but fortunately it is quite an easy matter to convince the well informed mind, by direct experiment, that the seat of the phenomena is mostly situated in the humours and secretions of the eye, and not in its nervous or sentient structure.

Entoptical phantoms are principally due: 1, to the passage of muco-lacrimal secretions over the surface of the cornea; 2, to corpuscles moving between the cornea and focal centres, or to corpuscles moving between the focal centre and the retina.

The increased occurrence of *visio phantasmatum*, under certain circumstances, offers an extensive field for experiment and research. When the eye is in a normal condition, the lacrimal fluids, as they float across the cornea, may be quite visible in the diffused light of day. Images of the deeper fibres, moving between the cornea and focal centre, may also be seen without the use of a pencil of light, whether convergent or divergent. And the number of apparent separate beads is apt to incline the observer to the opinion that there are loose beads in the vitreous humour. But all other entoptical objects require the aid of small pencils of light, to enable the observer to perceive and accurately describe them. Such aids are of course necessary before we can determine either the situation, extent, or precise nature, of any entoptical phenomenon. But when the eyes, whether from fatigue of the muscles, or any other disturbing cause, assume a morbid condition, the field of vision becomes peopled with images of all kinds; the number and distinctness of which—however painful to the sufferer—renders their investigation comparatively easy.

"To view entoptical apparitions with precision, and to determine their situation and dimensions—or rather to obtain data for determining them—we must

view them in a bright light of limited extent." (*Entoptics; with its Uses in Physiology and Medicine*. By J. Jago, M.D.) It is true that images of fibres in the vitreous humour, as well as certain spectra arising from eyelashes and conjunctival fluids, are frequently visible in the diffused light of day. Nay, in a diseased state of the internal eye, other entoptical objects obtrude themselves on the field of vision, as represented in the annexed diagram. (Fig. 1.)

Fig. 1.

These, with numerous other spectra, were always visibly floating in the right eye of a myopic patient, when that organ was weakened, and he was suffering from the effects of overwork. But no exact information can be obtained concerning these spectra, unless we follow certain particular methods of investigation; which I shall endeavour to make clear before proceeding to give the results.

However, first, let me say a word or two about a supposed test of the danger or harmlessness of entoptical apparitions mentioned by Dr. Watson; viz., "the simple and easy criterion is this, those *muscæ* which are motionless when the eye is at rest, and move with it when in motion, are signs of danger to vision; those which sink gently downward when the eye is fixed are innocent." This supposed test I have found utterly valueless; and mainly so, because patients, having no scientific knowledge of the subject, will content themselves with applying such a test and acting upon the result; frequently permit great mischief to go on in the eyes unchecked and unheeded; and need, again and again, to be reminded of the danger to which they thus expose themselves.

Now, the result of my experience is this, that blind or insensible spots in the retina do appear "to sink gently downward" when the eye is directed steadily towards some bright object. And Dr. Jago accounts for this when he says: "If the eyes be brought to bear, as is commonly done, on the top of some object, so that the suspected image may be viewed against the sky, they have an almost irresistible tendency to drop, and thus to cause the blind spot to drop also." And even if the object toward which the eyes are directed be not high above the level of the organs themselves, they yet have a tendency to sink downward or to move in some direction or other, thus causing the insensible spot to move also. Moreover, the force of imagination is such, that it is easy to fancy we detect a slight motion in an object when we know that such a motion is an assurance of safety; and even the most cool and collected observer can hardly be certain that the result of his observation will be entirely uninfluenced by his feelings and his imagination.

There are other, and more complicated, causes which render this test, supposing it were a true one, difficult of application. The more deeply situated fibres in the vitreous humour frequently cannot be detected to move along the retina; and, in diseases of the nervous system, *muscæ* occur, which, "like

* Myodesopsia (*muscæ volitantes*), usually defined "as any spectrum or visual appearance, which imposes on the patient, and leads him to think that flies are moving about before him in the air." (Dr. Mackenzie, "On the Vision of Objects on and in the Eye."—*Edinburgh Medical and Surgical Journal*, July 1845.) The symptom has also been very appropriately called *visio phantasmatum*; and, in my opinion, no better designation could be found.

dreams, are merely the result of efforts by a suffering brain to realise impressions made upon it."

Having thus premised, that accurate and scientific investigations are necessary to ascertain the nature of entoptical apparitions, the next step will be to describe some of the methods by which such investigations may be made. And here let me say, by way of caution, that care should be taken to ascertain that the lens we are about to experiment with is perfectly clean and free from dust. By looking at the flame of a steady-burning lamp or candle, and at the same time turning the lens on its axis, any particle of dust adhering to it will be seen to revolve, and must be carefully removed. Other imperfections, as scratches, etc., may be detected in the same way.

The first point of importance in making observations will necessarily be, how to obtain such pencils of rays, either convergent or divergent, as may conveniently, and without injury, be thrown upon the retina. I have found that light reflected from water, walls, roads, and other such-like objects, is far too dazzling to be at all agreeable or convenient; and should, therefore, recommend light drawn from a pure white cloud or the clear sky, as both convenient and trustworthy for entoptical experiments. By the aid of a convex lens, we may reflect into the eye, from such a clear sky, very fine divergent pencils of light. "If we look through a convex lens of one inch focal length towards a gas- or lamp-flame situated at the end of a moderately long room (say twenty feet), so that the image may be formed at or near the principal focus of the lens, that there may be produced a rapidly convergent and therefrom divergent pencil, the eye may receive.....a divergent or convergent pencil at pleasure." (*Entoptics*.)

If we use artificial light, care must be taken that the flame does not flicker—a steady light being indispensable for accuracy. With such pencils as those just enumerated, all the following experiments have been made.

A clergyman, of some scientific acquirements, myopic, in whose eyes *muscæ volitantes* have for years been most annoying and distressing, having been requested to furnish me with particulars of his case, says:

"I have not found any results worth noting in the apparitions arising from eyelashes and the movement of the lids; indeed, such can scarcely be called 'entoptical'—*ectoptical* seems a more suitable term for them, since their originating causes are external. In my case, the lubricating fluids do not appear to be as equally diffused over the corneæ and conjunctivæ as they should be, and probably are not in their normal condition; hence, numerous tears, both convex and concave, arise; two of which, as seen through a divergent pencil, are shown in the annexed figure 2. These are evidently convex tears, since they 'brighten the image, and give shade to the areola'; one, however, has a dark central spot. Figure 3 re-

"Throughout the crystalline lens are scattered numerous bodies, opaque or semi-opaque, having a round or oval outline, and always presenting a central brightness. The annexed figure 4 will give you

Fig. 4.

some idea of the appearance of these bodies. I am unable, even after careful investigation, absolutely to confirm the statement made regarding similar bodies, 'that the whole wide black ring is constituted of suitable internal fringes.' The shading of the areola around the objects is purposely given roughly, partly to imitate its actual appearance, partly to render the lucid band and central brightness of the opaque bodies more prominent; and, from whatever cause, these bright portions are invariably much more light than the surrounding areola; and they are, also, accompanied with prismatic bands, or circles of colour, which play about them, but which it is impossible to represent in a diagram, inasmuch as they are in constant motion, and present no definite outline. Fig. 5 is intended to represent the irregular outline of

Fig. 6.

coloured bands which surrounded a central spot of brightness upon a ground work of minute grey dots.

"It may, perhaps, not be out of place to detail the peculiarities of focal adjustment in my own eyes, as Dr. Jago has done in his. The power of accommodation, from a distance of only an inch and a half to the horizon itself, is possessed by both eyes when in their normal condition. But when a single horizontal straight line is viewed at a given distance—say twelve inches—and turned round in a plane perpendicular to the optic axis, it is seen more clearly in some positions than in others. A vertical line appears perfectly erect; but one sloping at an angle of 45° appears double. A horizontal line appears double with the left eye; but lately, and when the eyes are suffering from the effects of overstrain, on looking at a distant point, all nearer placed objects appear double, each eye having its own image, and not, as in Dr. Jago's case, one eye possessing two images. Moreover, this gentleman's double images 'become more widely apart as the objects become more remote.' My own case is precisely the converse of this; the nearer the object, supposing the eye to be directed to a distant point, the further apart are the two images.*

Fig. 2.

Fig. 3.

presents a concave tear, seen through a divergent pencil, the image dark, the areola surrounding it lighter.

* My patient's myopia is probably associated with *astigmatism*, due to some irregularity in the refracting surfaces of the eye, which I have had no opportunity of investigating. That distinguished philosopher, Dr. Thomas Young, first observed this asymmetry of the dioptric system in his own eyes. He was himself myopic; he saw in his optometer double images of the thread intersect one another at seven inches from the eye. "The optician Cary, to whom Dr. Young communicated his discovery, stated to him that he had often found that near-sighted people distinguished objects more accurately, when the glasses suited to them were held in a particular oblique direction before the eye. Now, by this means—at least, when strong

"With regard to the inspection of the fibres in the vitreous humour, I find that while observing intra-vitreous bodies, it is necessary to look downwards; and, indeed, if I fix the eye during such investigations upon an object above, or even parallel to, the axis of vision, I find that the images of intra-ocular bodies move about, so as to render their examination difficult. I have, by careful investigations, arrived at the conclusion, that all the seemingly loose beads in the vitreous humour are, in reality, parts of a series of filaments or fibres. The annexed figure 6

Fig. 6.

represents a portion of the net-work of fibres, and some loose beads visible in the vitreous humour, seen by means of a divergent pencil of light. In place of Dr. Jago's experiment, by which he appears to have arrived at this conclusion, I had an experience of a very different kind, but which led me to exactly the same opinion. When first I commenced these entoptical studies for you, the numerous apparently loose beads in the vitreous humours seemed totally unconnected; and when in motion, it was impossible to detect that they were in the condition of objects connected together, so far as similarity of movement and uniformity of direction were concerned. The annexed diagram (Fig. 7) represents some of these

Fig. 7.

Fig. 8.

loose globules, seen through a divergent pencil, when the eye was in a tolerably healthy condition. But soon after I had noted these, a period of close reading caused rapid deterioration of my sight; and one of the first of my annoying symptoms was the greater visibility of the beads in the vitreous humour. These daily increased, both in number and prominence; and I soon found that several (which, from their larger size or more conspicuous position, I

could easily recognise) were becoming united into a series of connecting links. In process of time, a regular network of fibres became visible; and in the diffused light of day, each fibre or filament was converted into a connected chain of beads (shown in fig. 8.) But, after a series of observations and experiments, I have come to the conclusion, that every bead which is visible in the vitreous humour, whether in the diffused light of day or by means of a divergent pencil, is in reality a portion of a fibre. 'I can at once locate in the tissue any thread that comes into view; and any globule that trembles upon the sight, I can restore to its place among the meshes of the web with facility.'

"To proceed to the entoptical investigation of the retina. At each contraction of the left ventricle of the heart, I can discern a corresponding movement in the arteries of the retina. These produce phantoms in the form of greyish elongated bodies, sometimes, though not invariably, phosphorescent. That the sentient surface of the retina lies behind the arteries seems most probable, when we consider in what way these phantoms are produced. But the experiments by which we investigate these phenomena are somewhat uncertain in their results; and consequently the data obtained from them are liable to many sources of error. As the result of careful observation, I may state that I can detect a very subtle black ring round most, if not all, of the capillary dots which fall upon the more sensitive portions of my retina; and I believe that, in some rare instances, I can observe a very slight central brightness. That the capillaries do not actually touch the sentient surface, although they approach it very nearly, appears certain. In my own eyes, as also in those of some other observers, a few excessively minute dots are just perceptible across the whole of the foramen centrale; but so minute as to be barely discernible. These small dots somewhat resemble the capillaries which lie around that region; although, of course, they must be very much smaller. These dots 'should be regarded as undoubted shadows; and, until the microscope shall have discovered another cause, it will be hard for me to persuade myself that they are not vessels.' The result of my investigations has led me to agree entirely with this view; and, consequently, to acquiesce in the presumption that this spot (i.e., the foramen centrale, which many say is without vessels) is really penetrated by excessively fine capillaries.

"With regard to the detection of bloodless portions of the retina, it is not always possible to discover them, or, at least, to distinguish them from mere harmless *muscæ volitantes*, by the uncertain test of their immobility; for—as I have before stated when the eye is directed towards an elevated object—they will sink gently downwards; and the observer will often rest satisfied with a cursory observation, shrinking from the possible discovery of danger to vision which a more carefully instituted examination might lead to. And when a more accurate series of entoptical experiments shall have been made and recorded, I think there will be little or no difficulty in detecting anæmic portions of the retina. It is true that they sink gently down, or at least appear to do so; but they will be found invariably stationary when the eye is directed to any spot on a level with, or lower, than its own elevation. You also have the ophthalmoscope to aid you in all such investigations; and can detect, by means of this instrument, other, and perhaps more decided, changes, not only in the retina, but throughout the fundus of the internal eye.

"Then, although the common harmless *muscæ* will still be seen to sink gently downward—occasionally

glasses are necessary—a certain degree of astigmatism may be corrected. Young also studied and delineated the form of the diffused spots. The source of astigmatism he sought in the crystalline lens, because it continued when he plunged his cornea into water, and replaced its action by that of a convex lens. He now assumed an oblique position of the crystalline lens as the cause, and even thought that from the diffusion-images of a point of light it might be deduced, that the two surfaces of his lens were not centred. In a double point of view, therefore, Young's eye, says Donders, 'presented an exception; the refraction was stronger in the horizontal than in the vertical meridian, and the cause lay principally in the lens.' (*Phil. Trans.*, vol. lxxiii; Young's *Miscellaneous Works*, edited by Peacock, vol. i, p. 26; Donders, *On the Anomalies of Accommodation and Refraction of the Eye*, p. 416.)

returning and then again descending—the phantoms from the lacrymal fluids move either laterally or longitudinally; at such times, the anæmic portions of the retina remain firmly fixed. And I fancy that I can now detect them by a peculiar colour, or rather shade, by which they are distinguishable from all other entoptical images; namely, a pearly brightness, difficult to depict without the aid of a skilful pencil; but when once seen, not to be forgotten. I need scarcely add that, as they are the most alarming, so they are also the most obtrusive of entoptical objects, being visible with as well as without pencils, and visible alike in daylight and by artificial light. They are more affected than any other spectres by overwork of the eyes; and I have invariably found them disappear after a sufficient period of rest, and return when the eyes were fatigued by much work; and, like all the other appearances I have mentioned, to be by far less annoying in the clear and brilliant sunshine of the South, than in the twilight of an English winter's day.

"It has been quite a source of employment for spare moments, to note the effects of external circumstances upon my *muscæ volitantes*. In the first place, reading or writing always causes with me some muscular contraction (a spasm of the voluntary muscles of the eye). This renders all apparitions very much more conspicuously visible. I have noticed that painting does not produce the same unpleasant effects, although pencil- or chalk-drawing does, but still in a far less degree than reading or writing. In fact, I have found it to be an invariable rule, one which may prove of use to others similarly affected, or suffering from weak sight (either associated with anæmia or hyperæmia of the retina), that any kind of employment which involves the looking at coloured objects, or the varied landscape, is not only far less trying than when the sight is exercised on black or white objects; but after the fatigue of reading, if I turn to my painting, or walk out for a while, the retina very quickly recovers itself. I may mention, however, that my retina appears to be at all times morbidly sensitive to light; and that any unusual printed characters, such as Hebrew, Greek, or German, are very trying to my sight. Entoptical objects also become most numerous after reading Hebrew. I append a portion of my field of vision, seen by the aid of a divergent pencil of light, after

ON IMPAIRED NERVOUS POWER, FROM ALTERATIONS IN THE QUANTITY OF THE BLOOD CIRCULATING IN THE BRAIN.

By GEORGE HARE PHILIPSON, M.A., M.B.Cantab., M.R.C.P., Physician to the Newcastle-upon-Tyne Dispensary and Fever Hospital, etc.

[Read before the Northumberland and Durham Medical Society at Newcastle-upon-Tyne, January 12th, 1865.]

THE morbid processes which influence the functions of the brain are various and widely different. Whatever the alteration, the effect is manifested by some loss of power or force, the extent varying, according as the mischief is simple or severe, implicating a portion of the nervous tissue of small consequence or absolutely needful for the continuance of life.

The mental power alone may be diminished. To this there may be superadded a suspension of ideas; the individual halting in a conversation, in the middle of a sentence, or of a word, not from a difficulty in articulation, but from losing the string of ideas owned at the time by his mind. The discoverable effect may be thus constituted; or, in addition, there may be a loss of one or more of the special senses, ordinary sensation or motion, with or without muscular contractions, diminished nutrition, reflex actions, and perverted sensations. Even life itself may be suddenly or more gradually terminated, external impressions previously producing no effect, the semblance being that of death, but with the continuance of the circulation and respiration. How gradual and regular is this progress. The signs are very distinct. Their coexistence is agreeable to order, and guides us to the portion of the nervous centre implicated, and to the nature of the lesion, whether it be due simply to functional disturbance, to alterations in the quantity or quality of the blood circulating, to effusion of this fluid into the substance or cavities of the encephalon, to softening, slowly generated, or to inflammatory or some other condition.

These states are each suggestive, and deserving of distinct notice. Nevertheless, the present inquiry will be limited to the consideration of the various conditions productive of alterations in the quantity of the blood circulating in the brain, the effects arising therefrom being specially referred to.

The quantity of blood may be augmented or diminished.

1. The increase may arise from general or partial hyperæmia. In general hyperæmia or plethora—that bodily condition in which the blood is either in excessive quantity, or not increased, but more rich in fibrine and red corpuscles—the circulation is easily quickened by any sudden excitement. The blood-vessels in every part of the body are over-distended; they contain an excess of blood. Those in the brain are very liable to suffer, and frequently rupture, solely from this cause. In a measure, they are ready prepared for this, from the delicate nature of their structure, and their nearness to the heart. This state may be the forerunner of congestion, or of that variety of partial hyperæmia characterised by sluggishness of the flow, and an increase in the actual amount of blood in the vessels. The veins are principally affected; before long they are over-distended, and finally loaded. Thus the blood accumulates, and by degrees the capillaries dilate, and, by reason of their thin coat, readily yield to the pressure, if the onward current be not re-established.

Any obstacle preventing the return of blood from the brain is the most frequent cause of congestion.

Fig. 9.

an hour's reading. A A, portions of fibre; B B, clusters of spectra, probably beads, in the vitreous humour, forming parts of larger fibres; C C, anæmic portions of the retina; D D, deeper fibres in the vitreous body. The background is shaded merely to give prominence to the spectra; and the oval indicates that the central part of the field is more thickly covered. All the images sink gently downwards when the eye returns to rest."

[To be continued.]

The impediment may be in the heart itself, at the right auriculo-ventricular aperture—more often from regurgitation than from constriction. The internal jugular vein may be compressed by an aneurismal or other tumour. The convulsions in severe cases of pertussis are due to congestion; and in this way, the capacity of the chest is diminished by oft repeated respirations, the lungs in proportion being compressed; the amount of blood transmitted through them is thereby lessened, and its return from the head impeded, where it collects. In congestion, it is not often that consciousness is entirely lost; convulsions and a temporary paralysis may occur; usually all the symptoms pass away before the third day.

The quantity of blood in the brain may be increased, the flow also being quickened. In this example of partial hyperæmia, if the increase be small, the functions of the brain are performed with increased activity. If it be greater, there are restlessness, apprehension of impending danger, inability to fix the attention, feeling of fulness within the head, at times slight stupor and delirium, readily increased by stooping. Most often the circulation after a little time becomes again tranquil, and all the uneasy feelings vanish. More rarely inflammation of the substance of the brain supervenes. At some part the blood stagnates, not from any hindrance to the flow, but from the blood-discs adhering together and to the walls of the capillaries. This is soon followed by an exudation from the vessels, either composed entirely of the liquid portion of the blood, or a blastematous lymph, which coagulates between the nerve-fibres and cells. The symptoms are severe. The carotid arteries pulsate with great force and increased frequency. The whole circulation is excited. The pupils, at first contracted, afterwards dilate, often unequally, any sudden light producing little effect. Vision is impaired. Certain muscles or groups of muscles become rigid. Motion and sensation are lost. Stupor and delirium, intense coma, or sudden collapse, shortly precede death.

2. A decrease in the quantity of blood circulating in the brain may arise from a sudden and large loss of blood, or from an interruption to the current in the arteries that supply or are distributed to the brain.

In acute anæmia, from any sudden and large hæmorrhage, the amount of blood passing through the brain necessarily must suffer diminution, the proportion of the composite elements being in no way changed. The giddiness, loss of consciousness, perhaps dreadfully prolonged, the momentary suspension of respiration, resumed with deep sighing, sufficiently mark the action upon the nervous system.

The blood may coagulate within a healthy or a diseased vessel. When within a healthy vessel, it does so spontaneously and during life. Rheumatism, syphilis, the puerperal state, and debility in any way produced, appear to render the fibrine more liable to separate and form a clot. Such cases are uncommon. The following one is a remarkable example.

T. B., a joiner, aged 43, on the morning of March 2nd, 1861, while at work fell to the ground; when lifted by his fellow-workmen, he was unconscious; two hours afterwards was profoundly insensible. The mouth was drawn to the right; sensation and motion were abolished in the left arm and leg; when raised they fell as dead weights; reflex action could not be excited; the intestinal contents were passed involuntarily. He never regained consciousness, and died twenty-two hours after the seizure.

At the autopsy, the right internal carotid artery within the cranium, together with its branches, were

distended with a coagulum, which even extended into the branches of the ophthalmic. The vessels were completely filled. When cut across, the circumference of the clot was firm, the centre soft, most like ordinary clotted blood. It was divided at several parts with the same result. The lining of the vessels was of a natural colour, and quite smooth. The brain was throughout of ordinary consistence. The ventricles contained the usual quantity of serosity. The valves of the heart were healthy.

It was conjectured during life that blood had suddenly become effused into the right hemisphere of the brain. At the examination a different condition was revealed—an explanation of the symptoms. The character of the clot was peculiar, and clearly pointed to its formation some time before death. In all probability the interior of the vessels was first covered with a layer of fibrine, and upon this, according to the rapidity with which the blood-discs became entangled, a coagulum was formed, enlarging until the vessels were ultimately blocked up.

In arteries inflamed, the blood coagulates. The clot is often firmly adherent, and of a uniform colour. The heart is moderately distended; the calibre slightly diminished. The external coat is thickened from exudation into its interstices; the internal softened, and devoid of its natural polish. In some bodily conditions, a lowness of activity naturally exists, joined with general impairment of the nutritive power. In various organs and tissues the proper structure is replaced by oily particles—plates of cholesterine and calcareous particles. In the arteries, this change is not uncommon in the contractile tissue of the middle coat. The vessels then lose their power of contractility, are dilated rather than contracted. The calcareous particles not unfrequently project into the current, sometimes becoming free, from removal of the epithelial layer by absorption, and thus inviting foundations are formed for the raising of a coagulum.

The blood may coagulate upon some substance derived from a distance, composed either of the constituents of the blood, or the products of some morbid process. This condition, with the appellation of "embolon", was described some few years ago near the same time, by Virchow, in Germany, and the much lamented Kirkes, in this country. They stated that fibrinous fragments or vegetations adherent to the interior of the great vessels, the valves or inner surface of the heart, by some sudden excitement of the circulation, become detached, and swept on in the circulation until arrested by a vessel too small for them to move in. The vessel becomes blocked by a clot to the angle of branching, where the circulation is still going on.

The embolus may be formed in various ways. It may be composed simply of a coagulum, formed upon calcareous spicule, projecting into the interior of one of the great vessels, or an atheromatous patch, where the epithelial membrane has been removed. It may be formed of fibrinous patches washed off from the masses attached or interwoven among the chordæ tendinæ and columnæ carnæ of the left ventricle of the heart. It may be constituted by a vegetation, detached from one of the valves of the heart, the result of previous endocarditis. The vegetations are usually attached to the free border of the valves, and to those of the left side in preference to the right. They are generally small in size, and pass into the cerebral arteries and their branches; the middle cerebral more often than the anterior or posterior. The fibrinous particles are of good size, and frequently lodge in the internal carotid artery.

The resting place of the embolus is principally determined by its size, the position of the body at the

time the separation has occurred, the velocity of the circulation, and the angles formed by divergent branches. When an artery so obstructed is examined, it will appear as if distended with artificial injection, the coats being quite healthy. The plug is firm, distinctly laminated, like the contents of an aneurism; in shape mostly conical, the base directed to the stream; smooth; like an ordinary clot in colour; the apex often irregular, lighter in colour, and possibly identical in structure with fibrinous masses or vegetations, yet undetached.

The changes that ultimately occur are chiefly influenced by the size and position of the artery obstructed. If it be the internal carotid artery, by reason of its numerous anastomoses with the branches of its fellow, and of the external carotid and the subclavian, the circulation is soon restored. If the embolus and the vessel be not adherent, the force of the circulation may produce dilatation of the vessel behind the obstruction, and the blood may gradually find its way between the plug and the vessel. In this way, the circulation may be in part restored. If the clot be firmly fixed, the dilatation may increase until the vessel ruptures. This is a rare cause of hæmorrhage into the substance of the brain. The embolus may be arrested at the angle of two divergent branches, loosely waving in one, and obstructing the other. This position may be easily altered, and the obstacle may again pass into the circulation, migrate, and obstruct some other vessel. The embolus may continue fixed in position, and gradually become less by a process of disintegration and absorption, the vessel once again becoming patent. When the obstruction continues some time, the nutrition of the brain suffers. Its consistence changes; it becomes soft, pulpy, almost diffuent at places, like cream in density and appearance; the extent of the alteration corresponding closely to the space within which the branches of the obstructed artery are distributed. In fatal cases, this is the most general *post mortem* appearance, death rarely following the immediate attack.

The symptoms are distinctive. The attack is most sudden, without premonitory warning. Consciousness is lost, after a few hours regained, disclosing partial or complete paralysis of one side. The face may be distorted, the tongue protruded to one side, the grasp diminished, and the foot trailed. Sensation is abolished, lessened, or perverted. Speech is defective, in the utterance of words, and even in the expression of ideas by signs. The paralysis is on the side of the body opposite to that in which the obstruction has occurred, thus agreeing with the distinctive character of cerebral paralysis from other causes. One side of the body may be completely paralysed, and the arterial pulsations in a part of the other be unable to be felt. Here embolism of the artery going to the part, is associated with a similar condition of an artery supplying the brain. Other internal organs in conjunction with the brain may be similarly affected; the spleen and kidneys more often than the liver. The first attack is often of short duration, succeeded by a second more lasting, it may be, of the opposite side of the body. In such the obstruction has become displaced, altered in position, and finally firmly wedged.

This condition may occur at any age. Of seven cases, three were under thirty years of age, while one was sixty-five. Four were males and three females. In every case a history of previous rheumatism was obtained, and the auscultatory evidence was clear of coexistent disease of the valves of the left side of the heart.

The treatment, immediate upon the seizure, must be directed to equalise and restore the circulation.

The recumbent posture must be strictly enjoined, and all constricting articles of dress set free. Some diffusible stimulant, as brandy or ammonia, may be administered. Some caution, however, is necessary, lest the circulation be excited in too great degree, and fresh particles of the obstructing matter become washed into the current. After consciousness has been regained, if the paralysis continue, the endeavour should be to hasten the absorption of the obstruction. Upon the supposition that ammonia possesses the property of liquefying the clot of coagulated blood, this alkali may be given. Even out of the body, upon the authority of Dr. B. W. Richardson, blood serum alkalified with ammonia possesses this property. Dr. Fletcher of Manchester (*BRITISH MEDICAL JOURNAL*, April 30th, 1864) has recorded a case of embolism which recovered, ammonia having been given in frequent and large doses. The symptoms were clear and well marked. The healthy nutrition of the body must be carefully maintained, so that, however small the quantity of blood is that the brain receives, it may be as nutrient as possible. With this view, a generous diet, wine and tonic remedies are indicated. Iron, quinine, alone or in combination with ammonia, or other approved absorbent, as the iodide or bromide of potassium, prove the most beneficial. Laxatives from time to time are necessary, and highly useful. Counterirritation behind the ear, or upon the crown of the head, by means of cantharidine blisters or the ointment of tartarated antimony, should not be omitted.

The foregoing considerations may be embodied in the following propositions.

An increase in the quantity of blood circulating in the brain, is alone adequate to produce impairment of its various functions.

The ulterior effects of the increase are much more serious than those of the increase itself.

A sudden diminution in the amount of blood distributed to the brain, is followed by complete paralysis.

Hemiplegia so produced, closely resembles hæmorrhage into or acute softening of the brain-tissue, not only in symptoms, but in power to destroy life.

CASE OF POISONING BY STRYCHNINE.

By R. J. ROGERS, M.R.C.S., late House-Surgeon to the Sussex County Hospital.

A FEMALE, aged 25, was admitted into the Sussex County Hospital, having, about an hour and a half previously, swallowed one of "Barber's Magic Vermin Killer" powders with suicidal intent.

When seen, she was stretched across a chair, with her legs rigid and extended, the trunk in a state of opisthotonos, and there were tetanic spasms of the muscles of the arms, neck, and face. With great difficulty, in consequence of the rigid state of the jaws, a tube was passed into the œsophagus; and, by the aid of the stomach-pump, a quantity of warm water was injected, which returned clear and of a pale green colour. She was then placed in bed. The thighs and legs were persistently rigid and widely separated; the muscles of the upper extremities, neck, and face, were in a state of violent spasmodic contraction. There were occasional short intervals of perfect quietude, during which she was quite coherent; and in one of these she stated the cause of her having taken the poison. Any sudden noise or movement caused an accession of the paroxysms. She was very thirsty, and constantly craving for

water. She was ordered the following draught every quarter of an hour for six doses.

R Acid hydrocyanici diluti (P. L.) $\text{m}\nu$; ammoniæ sesquicarb. gr. ij ; misturæ acaciæ ʒij ; aquæ destill. ad ʒss .

There was very great difficulty in swallowing. The pupils were widely dilated; the countenance was somewhat livid; the heart's action was forcible, but regular in its rhythm. No effect was produced by the medicine; and she died during an attack of more than usual severity about two hours after her admission.

Immediately after death, the following appearances were noted. The face, neck, and upper part of the chest, were of a livid colour; the teeth firmly clenched; the sterno-cleido-mastoid muscles were singularly prominent, hard, and strongly contracted. The arms were straight; the shoulder- and elbow-joints rigid, requiring great force to bend them; the fingers were tightly flexed. The muscles of the thighs and legs were also strongly contracted; and the united efforts of two persons could not bend the knees. The soles of the feet were arched.

About an hour afterwards, the muscles of the upper extremity were relaxing.

Three hours after death, the body was very warm; the lower extremities were relaxing. The knees could be bent; but the muscles were still rather hard.

Nine hours after death, the body was nearly cold; the rigidity of the muscles had nearly all passed off.

On examination of the body, twenty-four hours after death, there was great lividity of the face, neck, chest, and dependent parts. The flexor muscles of the forearms and legs were somewhat contracted; the hands were clenched; the soles of the feet were arched. There was unusual vascularity of the integuments forming the scalp. The surface of the brain was rather congested. The brain itself was quite healthy; there was no fluid in the ventricles. The spinal cord was healthy. There was nothing remarkable about the upper part of it, which only was examined. The lungs were intensely congested; there were a few tubercles in the apex of the right. The blood in the great vessels about the neck and chest was very dark-coloured and fluid. The pericardium contained two or three ounces of serum. The heart was flaccid; its cavities were quite empty; not a clot or drop of blood was to be seen. The blood throughout the body appeared unusually fluid. There were white silvery streaks on the surface of the abdomen, marks of a former pregnancy. The liver, spleen, and kidneys were healthy, but congested. The stomach contained several ounces of pale-coloured fluid; the mucous membrane was pale throughout. The uterus was large, weighing seven ounces and three-quarters. Its interior was lined with a white, flocculent membrane, easily separated, which, on microscopic examination, was proved to be decidua. There was a very large corpus luteum in the left ovary.

Some blood, pieces of liver and kidney, and urine, withdrawn immediately after death, were examined chemically by Mr. Peel, dispenser to the hospital, by Rodgers and Girdwood's process (*Pharmaceutical Journal*, vol. xvi, page 497.) In all these, distinct traces of strychnine were found. One of the powders, weighing 28 grains, was found on analysis to contain 2·8 grains of strychnine.

TESTIMONIAL TO MR. W. P. HOARE. A very flattering testimonial, consisting of a piece of plate and a microscope, was presented on the 4th inst. to Mr. W. P. Hoare of Faversham, by his friends. The Mayor presented the testimonial.

SOUTH EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

CASES IN OPHTHALMIC PRACTICE.

By MATTHEW A. ADAMS, Esq., Surgeon to the Kent County Ophthalmic Hospital, Maidstone.

[Read at Gravesend, March 31st, 1865.]

If in the account of the following cases it should appear to you, that I have neglected to report many important particulars, you will please to understand that it has been my object in arranging these few remarks, to condense the subordinate features of each case, and give particular prominence to those on which I would desire to raise a discussion.

Without further sacrifice of valuable time, allow me to bring before your notice what I believe to have been a case of *Diphtheria of the conjunctiva*.

Mr. Hutchinson describes a similar case in the *Ophthalmic Hospital Reports* for October 1859, which called forth some remarks in the January following, from Dr. Mackenzie of Glasgow, strongly arguing against the existence of such a disease. So it still remains a question, whether there is such a disease. If there is, How is it to be recognised? How should it be treated?

CASE 1. John Briggs, 9 months old, when first brought to me in May last, had been under Mr. Crook's care about a month for a purulent ophthalmia. In a letter to me on the subject, he says: "I found the child very ill in himself, with the eyes inflamed, and the eyelids lined with a tough whitish membrane, which I could not remove." And from the mother (who had two years previously to this time lost all her children—three in number—from diphtheria) I gained these additional particulars respecting its history. She first noticed that he failed in his health much as the other children did who had died of diphtheria. His appetite fell off; he was feverish and peevish; and after about a week the mother noticed a discharge from the left nostril, not clear like the discharge accompanying catarrh, but from the first thick, yellow, and fluid, precisely like the discharge she had witnessed in each of the three children before alluded to. On two occasions a piece of membrane came away with the discharge, and was shown to the "doctor," who decidedly pronounced it to be diphtheritic. After a time the right nostril became affected in a similar way, but never so severely as the left. By extension the eyes soon became affected, the left first. They were blood-shot, and discharged yellow matter; this was soon followed by a membranous deposit, first showing itself at the inner canthus, and gradually creeping over the front of the eyeball.

When I was consulted, I found the child very pale, the eyelids swollen, and of a livid purple colour, very red at the margin, and the lashes matted together, and a little thin puru-sanious discharge running down each cheek. On separating the lids, the peculiarity of the case at once struck me. From the strong resemblance it bore to what I had seen in the throats of those affected with diphtheria, I was led at once to put the question: "Have you had diphtheria in your house?" This question was not dictated by any preconceived notion on the subject. At that time I was not aware of Mr. Hutchinson's and Dr. Mackenzie's papers on the subject. The ocular conjunctivæ and corneæ were covered with a tough inflammatory exudation, any attempt to remove which

left a raw bleeding surface. In all this the left eye was the worst, the right cornea being in part clear.

I put a drop of a twelve-grain solution of nitrate of silver into each eye, ordered some drops of a solution of sulphate of copper to be used three times a day, and the eyes to be cleansed with an alum lotion every quarter of an hour. I also prescribed an iron mixture, beef-tea, and port wine.

After a time the child quite recovered. The cornea were only slightly damaged, considering the severity of the disorder; but after the lapse of a month or more, he had another attack as bad as the first. I persuaded the mother to change her residence from a low marshy place at Northfleet; and ultimately the child again pulled through it.

I leave it to you, gentlemen, to say whether you consider this case in any way settles the vexed question. And I hope to elicit some discussion with reference to the diagnosis and proper treatment of a disease which I am inclined to believe by no means very uncommon.

Diabetic Cataract. The next two cases to which I ask your kind attention, possess for me great interest.

Lydia Meopstead, aged 54, and Amy Sage, aged 33, were and are suffering from diabetes; they had a well formed cataract in each eye.

I take it for granted that since the publication of Mr. France's paper in February 1859, On Cataract in Association with Diabetes, and Dr. B. W. Richardson's account of what he terms the "synthesis of cataract," all the profession admit the consequent connection of cataract with diabetes. What is the physical cause of this connection? Why should the connection be so seldom, comparatively, exemplified? Although these are questions of great interest, we cannot now spare time to discuss them; but must confine ourselves to the consideration of the proper treatment of these cases.

Mr. France, in the paper alluded to, concludes with these words: "My experience would lead me strenuously to deprecate any operative interference with them, so long as any useful degree of vision is preserved."

If this advice be well founded, it is almost prohibitive of effectual aid; on the other hand, should future experience modify this opinion, needless suffering may be saved and much good done.

CASE II. Lydia Meopstead was admitted into the Kent Ophthalmic Hospital on the 15th of last November. She is a married woman, has had a large family, and had suffered from diabetes more than four years. Two years before admission, her right eye began to fail her, which gradually became worse, so that on her admission she could only just discern light from dark. She was most emaciated and extremely feeble.

She passed in the twenty-four hours three and a half quarts of strongly saccharine urine, of specific gravity 1038. This state of the urine varied very little during the time she was under my care. A less promising case could hardly be imagined, nor could vision so very imperfect be made less useful. Under these circumstances we decided upon an attempt at extraction, which was accomplished in the right eye on November 30th by Schuff's method. On the third day after the operation she was allowed to sit up; the section was quite healed, and the eye free from any adverse symptom. Unfortunately she was attacked by diarrhoea, and some iritis set in. This was soon checked, and on December 5th—that is to say, five days after the first operation—I performed a large iridectomy on the left eye preparatory to extracting the lens by Van Moeren's method. On December 20th the extraction was completed on this eye. All

went on well, and in eight days she was discharged cured. At this time she could see distant objects distinctly with + 3½, and with + 2½ read No. 3 type at 10 inches, a result very little short of normal vision.

CASE III. Amy Sage, aged 33, was taken into the hospital on February 2nd, having just previously been an inmate of the West Kent General Hospital, under Dr. Woodfall's care, for diabetes. She is a married woman, has had twelve children, and dates the commencement of her disorder from her last confinement a year ago. The blindness began to trouble her last August, and gradually became worse. On admission, she could not distinguish objects, but had good quantitative perception of light and shadow. She passed daily six pints of urine, highly saccharine, of a specific gravity 1038.

On February 24th, I made a small valvular opening in the cornea of the right eye with a broad needle, lacerated the capsule, and inserted the suction curette, and with it drew out a large portion of the lens; still there was a very considerable portion which refused to pass in at the mouth of the curette. Nothing further was done on this occasion.

Ten days later, the anterior chamber was again opened with a broad needle, enough to admit a small Schuff's spoon, with which the remainder of the lens was removed. Ice was applied, and by the 11th, the eye was convalescent.

On the 22nd, eleven days since the last operation, the left eye was treated in a similar manner. On this occasion, however, we succeeded in removing all but a very small portion of the lens by the suction curette; so little, indeed, remained behind, that it was left to disappear by solution. She complained of much pain directly after the operation, which was relieved almost immediately by the application of ice.

I cannot refrain from remarking here, how eminently useful I have found ice under these and similar circumstances for the assuaging of pain. I am not aware that it has been used in ophthalmic practice with this view, and I beg to offer my humble testimony in favour of a very valuable therapeutical agent.

The woman now sees well; I believe as well as it is possible for any person to see after the removal of the crystalline lens; she has excellent vision for distant objects, and with proper convex lenses reads the very smallest type.

One other circumstance, confirmatory of the nature of the disorder, I must allude to. The part of the lens which was removed at the first operation on this last patient by the suction-curette, I subjected to the usual test for sugar, and obtained an abundant reaction characteristic of that substance; and, although one might presume that such would be found to be the case, as far as I know, no record exists of the fact having been demonstrated.

It remains only for me, in a few words, to draw especial attention to the operations employed in these two patients.

Each of the four eyes was treated differently. In the first operation on Mrs. Meopstead, I adopted the method of Schuff, believing, from the age of the patient and the appearance of the cataract, that a hard nucleus existed. This proved to be the fact. As is almost always the case with this operation, some hæmorrhage took place from the iridectomy into the anterior chamber, much obscuring the subsequent steps of the proceeding; so that after lacerating the capsule and extracting the hard nucleus of the lens, I was somewhat in the dark as to how much of the cortical portion was remaining, and was obliged to content myself with scooping out just as much as I felt

I could without risk of rupturing the hyaloid membrane or doing other mischief (for I may be allowed to remark that, I consider this operation an extremely delicate one—far more so than the old flap extraction). This hæmorrhage, then, made it almost impossible to avoid leaving a portion of the cortical structure behind; and to this I chiefly attribute the attack of iritis which set in on the third day. Improving on the experience of this first operation, and finding the cornea so ready to heal, I chose Van Mooren's for the second eye, and secured a better result, as good as that obtained by the other.

With the patient Sage, however, the case was rather different. She was only 33 years old. The lens was very bulky, and by its appearance led one to believe pretty confidently that there was no hard nucleus; and I am convinced the suction curette ought to have removed the whole of the lens. As it was, however, only the more fluid portion came away, and the remainder had to be extracted on a subsequent occasion by a Schutt's spoon.

As the suction operation is quite a new introduction into practice, I had not hitherto had experience enough to detect an imperfection in my instrument. Before operating on the left eye, I corrected the fault, and to my mind, it left nothing to be desired in the operation.

In conclusion, I trust that the history of these two cases will remove some of the gloom which necessarily hung over these unfortunate cases of diabetic cataract, and I hope the discussion which they may call forth will sanction the various operative procedures applied to each of them.

CASE IV. *Congenital Absence of the Eyes.* A very few words will despatch the remaining case which I bring before you.

It is that of a poor child, S. A. Doret, born without eyes. This condition, which goes by the name of *anophthalmos*, I believe fortunately to be very rare; and it is chiefly as a curiosity that I have ventured to bring it before you to day. The mother, 20 years old, is a healthy woman, and this is her second child. It appears to have been born at the full time—that is to say, on February 13th, she having last menstruated on the 26th of the previous April.

Whilst she was pregnant, about the fourth week in the third month, her eldest little girl fell down and injured her forehead, which gave rise to an abscess as large as a hen's egg. The inflammatory swelling which accompanied it caused the eyes (as the mother describes it) "to be sunk right into its head." She says it made a strong impression upon her mind, and she could not help talking to her husband about it, and hoping the child to be born would have nothing the matter with its eyes.

The child's eyebrows are perfect, so indeed are the eyelashes, but the lids are to a great extent adherent at their margins. As, however, the little child is here, I will not trespass any longer on your very indulgent attention.

[The child was exhibited to the members present. On careful examination, no trace of eyeball could be detected beneath the lids.]

SCIENTIFIC EXPLORATIONS. Professor Agassiz is about starting on a scientific exploring expedition to the tropical regions of South America; first, to test his glacial theory of the changes in the heat of the earth; secondly, to collect specimens for a grand museum of comparative zoölogy. The expense is borne by Mr. Nathaniel Thorpe, who says to the Professor: "Select your men, organise and go forward with the expedition, and send all the bills to me." (*Philadelphia Reporter.*)

Reviews and Notices.

LECTURES ON PUBLIC HEALTH, delivered at the Royal College of Surgeons. By E. D. MAPOTHER, M.D., Professor of Hygiene, Medical Officer of Health, City of Dublin, and Surgeon to St. Vincent's Hospital. Illustrated by Twenty Woodcuts. Pp. 276. Dublin and London: 1864.

THESE *Lectures* have been reprinted from the pages of the *Dublin Medical Press*; and Dr. MAPOTHER has done well in thus reproducing them in a separate form, for the benefit of all whom it may concern in general, and of the inhabitants of Ireland in particular.

We learn from the opening passage of the introductory lecture, that to the College of Surgeons of Ireland is due to the credit of having, so long ago as 1844, founded a Chair of Hygiene. The functions of its occupier, however—if not his existence—appear to have remained in abeyance until a year or two ago, when the appointment, together with that of Medical Officer of Health to the City of Dublin, was conferred on Dr. Mapother; one of the earliest results being the delivery of the very complete course of lectures now before us.

The greater part of the volume is taken up with remarks on the staple subjects of a hygienic course—air and ventilation, water, food, the skin, bathing, and clothing, mental and physical exercise and occupation, sanitary architecture, etc. In the latter lectures of the book, the author adverts more particularly to Ireland; and in that island he finds (in accordance with what is well known) much room for sanitary improvement, and much room for hope, if such improvement be carried out.

"The physical type of the Irishman, as has been proved on every battle-field in Europe, on the prairies of the West, and in the wild Australian bush, is inferior to that of no other variety of our species. We are blessed with a fertile soil and a genial climate; our coasts swarm with food, a rich harvest for Cornish, Manx, or Scottish industry; and, although no great arsenal or dockyard gives employment to our people, our harbours and estuaries are not surpassed by any in the sister kingdom. There is no reason why our people should not be industrious, cleanly, respectable, and prosperous, if we only resolve that they shall be so, and if we endeavour to undo, by every legitimate effort, the evils which have been gathered on us through indifference or neglect."

Dr. Mapother is working earnestly for the sanitary good of his country. May his success be complete!

The author addresses himself to a mixed audience, professional and lay; and primarily to the inhabitants of Ireland and its capital; but the plain and instructive character of the language, the general applicability of his remarks, and the convenient size of the book, induce us to recommend the perusal of these *Lectures on Public Health* to all whom sanitary matters may concern.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF LONDON. Vol. VI, for the Year 1864. Pp. 311. London: 1865.

THE reports of the meetings of the Obstetrical Society have already appeared in the pages of the

JOURNAL. It is, therefore, unnecessary to say more of this volume, than that the papers of which we have given abstracts are here published in full, together with the discussions which followed their reading. This volume, like its five predecessors, contains papers highly creditable to British obstetric practice. Among the contributions most specially deserving of notice is a very elaborate paper by Dr. Greenhalgh on the Treatment of Placenta Previa, enriched by the records of cases, and by carefully prepared and analysed statistical tables.

THOMSON'S CONSPPECTUS OF THE BRITISH PHARMACOPŒIA. Twenty-fifth Edition, corrected and made conformable throughout to the New Pharmacopœia of the General Council of Medical Education. By EDMUND LLOYD BIRKETT, M.D. Cantab., etc. London: 1865.

WE are glad to find that our old friend, the *Conspēctus* of the three Pharmacopœias, is still to live. Its functions have not ceased, although the three Colleges have amalgamated their Pharmacopœias into one. The *British Pharmacopœia* requires "conspēcting", as all of us well know. "It is as necessary as ever," says the editor, "to hold *in conspectu* the prominent points of pharmacy, materia medica, and therapeutics." And this is the chief business which the *Conspēctus* now proposes to undertake, and which it has, in our opinion, very well performed. The little volume will be found of as much service in its present form to the student and the practitioner, as it was in its former state.

A HANDBOOK OF OBSTETRIC OPERATIONS. By W. S. PLAYFAIR, M.D., M.R.C.P., Assistant Physician-Accoucheur to King's College Hospital. Pp. 232. London: 1865.

THIS book is apparently written with the view of bringing together the most trustworthy opinions on the employment of the various obstetric instruments and operations, so as to afford the practitioner a ready guide in time of emergency. In ten chapters, Dr. PLAYFAIR gives an account of the Induction of Premature Labour; Version or Turning; the Forceps; the Vectis or Lever; the Fillet and Blunt Hook; the Cæsarean Section and Gastrotomy; Vaginal Hysterotomy, Incisions, etc.; Symphysectomy and Pubectomy; Operations Involving the Destruction of the Fœtus; and Transfusion of Blood.

The general plan of each chapter is this: first, an historical account of the operation is given; then the object of the procedure, its indications, the modes of carrying it out, etc., according to the opinions of leading obstetric authorities, are noticed; and finally—except in the case of such operations as symphysectomy, regarding which, being not employed, no rules can be given—a summary of rules is given in numbered paragraphs. By reference to these, the practitioner will see at once under what circumstances it is considered warrantable to do or to omit this or that operation, or to use this or that instrument, and how, according to the case, the proceeding undertaken should be modified.

The book is apparently well calculated to fulfil its object.

TRANSACTIONS OF THE ETHNOLOGICAL SOCIETY OF LONDON. Vol. III. New Series. London: 1865.

WE hail with real pleasure the appearance of this new volume of the *Transactions of the Ethnological Society*, forming, as it does, a valuable repertory of the progress of the science amongst us. As contributors to the present volume, we are glad to see the names of Mr. L. J. Beale and Mr. Dunn, from our ranks. It is delightful to notice the unrestricted freedom which all the authors of the papers exercise and enjoy in the expression of their opinions. Among them, the monogenesis and the polygenesis of man is still a *questio vexata*, and is likely to remain so; although, since the publication of Sir Charles Lyell's work *On the Antiquity of Man*, and the bearing of the geological evidence upon it, many of the difficulties and obstacles which beset the monogenetic hypothesis, and which were once thought to be insuperable, now seem to be surmounted.

Mr. Wallace, in his remarkable paper, "On the Varieties of Man in the Malay Archipelago", while admitting the transition of the Chinese or Tartar into the Malay type, and looking upon the brown New Zealanders, the black Papuans, and the yellowish Alfuries, as varieties of one type, maintains that it is only by the admission of the high antiquity of man that we can possibly escape from the polygenetic theory of his appearance upon earth.

Mr. Christy,* in his valuable paper, "On the Prehistoric Cave-Dwellers of Southern France", advocates the unity of the origin of man. The facts he has brought forward (he says) can only be fairly interpreted in favour of a far higher antiquity for man's existence upon the earth than was once assigned to it; and, further, that "these and kindred researches are, in a degree, doing for the chronology of man, what geology has already done for the earth's crust"; but, at the same time he adds, "I am bound to confess, that hitherto nothing in the investigation of the works of uncivilised or pre-mature man, either of ancient or modern times, appears to necessitate a change in the old cherished idea of the unity of the human race."

On the other hand, the venerable Mr. Crawford, the Nestor of the Society, in his paper "On Sir Charles Lyell's Antiquity of Man", and on Professor Huxley's "Evidences as to Man's Place on Nature", boldly and openly avows,

"The conclusion seems to me inevitable, that the earth could not have been peopled throughout from a single tribe or family; and that all the theories founded on this assumption, are but the wild and incoherent dreams of learned and ingenious men, giving full rein to their imagination."

Besides the papers of Mr. Beale and Mr. Dunn, the volume contains many others of great interest and importance.

Mr. Beale's paper, "On the Brain and the Skull in some of the Families of Man", and Mr. Dunn's, "On the Psychological Differences which exist among the Typical Races of Man", have something in common, and are well worthy of being carefully studied. Mr. Beale observes—

* The recent and unexpected death, in France, of this truly worthy and estimable man, at the very time he had been proposed by the Council of the Royal Society for being elected a member, is much and deservedly regretted.

"Unless the measurements of the skull can lead to some practical results, it will be useless to record them; unless they indicate something from which we can draw conclusions useful to science, the inquiry will only be lost time. But, if we are warranted in believing, that the brain is the organ of the mind, and that the skull does to a great extent reveal to us the size and shape of the brain, it is difficult not to hope and to believe that the study of the skull in the various families of man will give us some information as to the functions of the various parts of the organ on which the skull is moulded."

Mr. Dunn, in his paper, says—

"The time has now come, and the opportunities are neither few nor far between, for us not to be content with a mere external survey of the skull. We are called upon to remove the bony covering, and, under the guidance of the chart provided for us by the indefatigable Gratiolet, assiduously to study and carefully to contrast and compare the sizes of the lobes, and the complexity of the developments of the cerebral convolutions, in all the races of man."

With a view to elucidation and better understanding of the psychological differences which exist among and characterise them. He laments to confess that the cerebral physiology of the typical races is still a *desideratum*. He adds—

"To our shame be it spoken that, notwithstanding our extensive and daily spreading intercourse with all the nations of the earth, hitherto little or next to nothing has been done in furtherance of the investigation of a subject so fraught with interest, and pregnant with consequences of such deep importance."

Mr. Dunn has a definite object in view in his paper; viz., to indicate to physiological ethnologists a field of investigation and inquiry, which (he thinks), if thoroughly explored, cannot fail of throwing light upon the causes of the psychological differences which exist among the typical races of man. Among the different races (he observes), there has often been noticed a marked superiority on the part of the savage over the civilised, in the force of their instincts and in the acuteness of the organs of sense; but that it is in their intellectual manifestations that the widest and most striking differences are seen. So striking and so great indeed is the intellectual inferiority of the Bushman, the Australian, and the Negro, to the Indo-European, that their claims even to our common humanity have been denied to them, and they have been treated as "wild fowl and cattle". Such being the case—to every physiological ethnologist, how important must be the inquiry, and incumbent the duty, to examine, compare, and contrast their cerebral organisation; seeing that it is upon nervous instrumentality—the vesicular matter of the encephalic ganglia as its substratum—that the mind is dependent for manifestation of all its activities, and among all the races of man. He views in contrast the aboriginal races of Africa and North America—the Negro and the Red Indian—with the intent to see what light the differences in their cerebral organisation throw upon their respective characters, mental manifestations, and destinies. The subject is treated in a manner worthy of the author of the papers on Medical Psychology which have appeared in our pages, and will be read with pleasure and profit.

British Medical Journal.

SATURDAY, MAY 20TH, 1865.

HOSPITAL STATISTICS.

Dr. F. BUCKLE has published an account of the "Vital and Economical Statistics of the Hospitals, Infirmarys, etc., of England and Wales, for the year 1863." Such a work contains materials of national importance; and we trust that the special attention thus drawn to the subject may induce the authorities of hospitals to adopt some general method of taking their statistics, and more fully to record them. As Dr. Buckle well says, considering that about 2,000,000 patients, at a cost of about £500,000, are annually treated at our hospitals and infirmaries, the supervision of the expenditure deserves careful attention.

Dr. Buckle gives some remarkable statistics showing the enormous, or rather abnormal, annual amount of work done by London and country hospitals. At hospitals during 1861,

In London alone, 1,018,940 patients were treated (41,567 in, and 977,343 out). Taking the population at 2,803,034, as by census of 1861,

The proportion of in-patients to population would be as 1 to 67.43;

The proportion of out-patients to population would be as 1 to 2.86;

The proportion of total number of patients to population would be as 1 to 2.75.

In England and Wales (exclusive of the metropolis), 911,640 patients were treated (80,068 in, and 831,572 out); the population being 17,258,691.

The proportion of in-patients to population would be as 1 to 215.55;

The proportion of out-patients to population would be as 1 to 20.75;

The proportion of total number of patients to population would be 1 to 18.93.

At an average cost of £2:15:0, the } £334,496 5 0
121,635 in-patients would cost ... }

At an average cost of half-a-crown, } 226,118 2 6
the 1,808,945 out-patients would }
cost

Making the total cost of the 1,930,580 } £560,614 7 6
patients amount to

From this it would appear that about one-third of the population of London receives gratuitous medical advice! But, no doubt, there is a fallacy in these statistics; and the fallacy is well worth recording on account of its cause. It appears that nearly 980,000 of the sick are out-patients; and we will venture to say that London cannot supply anything approaching to such a number of sick persons in one year. It is absurd to suppose that every third person in London is a hospital out-patient during the year! The explanation of the error is, no doubt, to be found in the shamefully puffing and exaggerated sta-

tistics which certain medical institutions, week after week, throw into the eyes of the public. Truth enough, however, remains in the statement to show the outrageous extent to which gratuitous medical advice is carried in London.

As regards nursing, Dr. Buckle remarks that, in those charities where the nursing, etc., is under the control of a lady-superintendent, "a higher moral tone pervades the establishment, than where it is under the management of a matron."

The number of patients allotted to one nurse varies greatly in different hospitals.

"In St. Bartholomew's Hospital there is on an average 1 nurse to every 6 patients (1 sister and 3 nurses to every 26 beds, the nurses taking night duty alternately); King's College, 1 to 7; Westminster, 1 to 8; Bedford, 1 to 7; Aylesbury, 1 to 12; Cardiff, 1 to 13; Reading, 1 to 13.75; Halifax, 1 to 15; Hertford, 1 to 17; Huntingdon, 1 to 17; Bolton, 1 to 20; Lynn, 1 to 21; Newark, 1 to 22; Durham, 1 to 24; and Etruria, 1 to 37."

The cubic space of air allotted to each patient, again, varies greatly, ranging from 350 cubic feet as at Lynn, to 1852 as at Brighton. Diets also vary very widely.

Dr. Buckle, also, seems to have been greatly struck by the differences in the average cost of patients in different hospitals; and well says that a general government inspection would do much good in this respect. As a proof of what may be done, he quotes the Lynn Hospital, "where the average costs have been reduced nearly fifty per cent. as compared with the previous twelve months."

He also very properly points out the abuse made of these charities by patients who are in receipt of relief. "The practice merely burdens the charity with expenses which should properly be met by the unions."

He also alludes to a fact mentioned by Dr. Richardson; viz.,

"That the average cost per week of patients in lunatic asylums, where the medical men are remunerated, is about eight shillings; while a patient in an hospital where the professional staff attend gratuitously costs twelve shillings. Would it not be well to try if having a paid medical staff in a hospital would not really be to the interest, financially, of the institution?"

Dr. Buckle's statistics again show the remarkable differences in the cost of patients in different London hospitals; and will naturally lead economists to inquire into the causes of the differences. In the Westminster Hospital, with 191 beds, each in-patient costs £2:2:8; and in the Metropolitan Free Hospital, with 21 beds, £6:16:0! At the Brompton Consumption Hospital, the patient costs £5:1:11; at St. Bartholomew's, £3:5:0; at St. Mary's, £3:17:0. We remember some time ago pointing out the very remarkable fact, that in one year St. Thomas's Hospital (before it left London Bridge) received exactly the same number of in-patients as

St. George's Hospital, and spent very nearly double the sum of money in doing the work—£30,000 as against £16,000. St. George's is governed by an open board, and St. Thomas's by a very close board; can the explanation be sought in this fact?

The thanks of the profession are due to Dr. Buckle for the very laborious work which he has performed. Let us hope that his attempt may induce the medical staff of hospitals throughout the country, and their governing boards, to adopt some general plan so as to enable the statistician still further and more effectually to utilise the materials they can supply.

At another page will be found a letter from Dr. Septimus Gibbon, with a petition which has been presented to the House of Commons from the President and Secretaries of the Metropolitan Counties Branch on the subject of the Chemists and Druggists Bill. The Committee which was last year appointed by the above-named Branch, for the purpose of watching the progress of such Parliamentary proceedings as may affect the medical profession or the practice of medicine, has bestowed much careful attention on the bills to regulate the practice of chemists and druggists; and it is to be hoped that their representations will have due weight with the legislature. No one can question that both the matters referred to in the petition are of the highest importance; and the profession must feel indebted to the Metropolitan Branch Committee, and especially to its energetic Secretary, Dr. Gibbon, for the zeal and judgment with which they have performed the duties entrusted to them.

Our readers will be pleased to learn, that the question of the army and navy medical officers is likely to be again brought under the notice of the College of Physicians. It would appear that the general sympathy of the College is strongly with our army and navy medical brethren; and it is generally understood that the late expression of the College on the Report of its Committee was rather directed against the Report itself, than against the proposals contained in it. We are satisfied that the College, when not misled by the dictum of semi-official and half-speaking voices, will see that it is its duty to take action in the case. We have it on the very best authority, that the intervention of the College, so far from prejudicing, would very greatly assist in removing the grievances of which our army and navy medical brethren complain. And is it not manifestly the duty of a college which is so often consulted by the Government on behalf of the soldier and the sailor, to tell the Government the positive fact—that they regret to find that medical teachers throughout the country advise their students to shun the army

and navy services? Is it not the duty of the College to tell the fact—that our army and navy are not provided with the best medical advice which the profession can supply? Is it not the duty of the College to tell the fact—that the best men do not enter those services, and solely because of the injustices to which they are there subjected? Is it not the duty of the College to ask the authorities to remove the injustice; and in order that the College may sanction and recommend the entrance into the army of our best class of medical students, thereby providing for our army and navy the best medical advice?

PROFESSOR BOECK, from whose pen a very interesting paper on the subject of Syphilisation will be found in another page of the JOURNAL, has, we hear, been summoned from Christiania to attend a patient in this country. Probably the Government Syphilitic Commission, which we believe is still carrying on its investigation into the complex and still obscure subject of venereal diseases, may think it well to take advantage of the professor's presence here, and to summon him before them, to learn from his own lips his profession of faith in syphilisation, and his opinions touching the nature of syphilis.

THE *Wiener Medicinische Wochenschrift* of the 10th inst. says, speaking of the St. Petersburg epidemic, that there is nothing new to tell. Foreign physicians there are kept completely in the dark about it. Why do they not, asks the journal, give us a distinct description of the appearances of the disease? Why not give us details of a *post mortem* examination? The reason is, that they are not in a position to do so. They are received most courteously and kindly, but no information is given them. They are *fêted* and dined, but blinded as to the facts of the epidemic.

MR. MACDONALD STEVENSON again takes up the subject of hospital carriages in the *Times*. We trust our brethren will use their influence in support of his excellent proposal. And the moment is opportune, for typhus is admittedly on the increase. He states that arrangements are in progress to provide for the removal of the contagious sick from their homes to the hospital. It is proposed to commence at once with the London Fever Hospital and the Small-Pox Hospital, and to provide suitable carriages, which should be always available. The carriages will be built expressly to facilitate constant cleansing, with extra springs, India-rubber tires to the wheels, and a separate *coupé* in front for those who accompany the patients. The working will be simple and attended with no trouble. As an example of the risks which are incurred yearly, we are told that upwards of 3000 fever cases were admitted last year to the Fever Hospital alone, and that of these

many are still conveyed in street cabs. One instance of the result is given.

"A cabman drove a London physician to a house where a patient had been suffering from small-pox. On arrival the patient was dead, and the blinds were drawn down; and, when the physician returned to the cab, the driver inquired if a death had occurred in the house, and what was the cause. The circumstances having been explained to him, the conscientious cabman stated that two or three weeks before he had driven a lady to the door in question immediately after having taken a patient to the Small-pox Hospital. The lady turned out to be the patient now dead; and the period between the occupation of the infected cab and the commencement of her illness corresponded to the time which the disease ordinarily requires to develop itself."

Several parishes have already anticipated the public need, and have provided special conveyances for the workhouse purposes. What is now required, is the support of the public, and subscriptions to the Hospital Carriage Fund can be paid to the London and County Bank, where accounts have been opened in the joint names of Dr. Murchison, Mr. Hills, and Mr. Stevenson, as a working committee to carry out this much needed sanitary measure, and to relieve the public from a fertile source of infection and contagion.

THE Poor-law Board have sacrificed another scapegoat, to purge itself, and transfer to the shoulders of others the odium necessarily attaching to the system which it administers. Dr. Craig, as may be seen, has been dismissed from his office of medical officer to the St. Giles's Union, on account of alleged neglect in the case of a pauper named Gibson. Without in any way entering into the merits of the case, we state without hesitation that the fault and blame in cases of this kind attach infinitely more to the system than to the unfortunate doctor who carries it out. The Poor-law Board knows as well as we do that the sick pauper never will or can receive proper medical attention and advice so long as the medical pay is such as it now is. It is very well for this Board, with sanctimonious visage, to exhibit its broad phylactery, and, in well sounding phrases, to publish its pretended anxious care of the pauper to the world; but in its conscience it knows well enough that it is defending a mere sham; and that on the present, as on previous occasions, the dismissal of the doctor is a mere blind.

THE fifth number of the *Ophthalmic Review* well sustains its character of a scientific exposé of the doings of ophthalmic surgeons. Mr. Lawson has in it a paper on the Accommodation-power of the Eye; Mr. Vose Solomon gives a case of Annular Synechia and Cataract of the Right Eye; Mr. Laurence gives cases of Retinitis Pigmentosa; then follow a Report of the Proceedings of the Heidelberg Ophthalmological Congress; a Retrospect of British and Foreign

Medical Journals, by Mr. Windsor; and a continuation of a critical abstract of Donders's famous work, lately published by the New Sydenham Society. The number opens with an article on Ophthalmic Surgery at Home and Abroad, wherein are fairly discussed the analogies and differences and idiosyncrasies of English and German ophthalmic students.

In a lecture lately given at Vienna, Hebra says:—

"Pustular diseases of the skin described by authors under the name of impetigo, ecthyma, porrigo, achor, etc., do not exist as essential diseases; they are merely accidental to, or the consequences of, other skin-diseases, which are recognisable by other signs than those of pustular eruptions, and generally, indeed, before the pustular eruption appears. Consequently, in dealing with pustules of the skin, our business is, not to trouble ourselves about the size, form, and number of the pustules, but to learn what that particular disease is which preceded the pustular eruption. We must never forget that a large number of pustular diseases are produced by local irritation, and should, therefore, in the first place, search for traces of scabies, of prurigo, pediculi, etc. Then, again, the diagnostic marks of the real cause of the pustules may have disappeared when the pustules come under our notice; as in scabies, as in the vesicles of eczema, the papules of prurigo, etc. The development and death of pustules usually take place in a similar way. All pustules resemble each other. It is impossible to distinguish the pustule of variola from that of acne, of syphilis, of scabies, etc.; neither do the size, nor the contents, nor the form of the pustules give us any distinctive sign. Even the depression of the pustule, supposed to be diagnostic of small-pox, is observed in all other pustular diseases—that is, as long as the contents of the eruption have not become completely purulent. The mere observation of the pustules, therefore, does not enable us to decide the nature of the disease; we must observe their whole course, their seat, etc. The words impetigo and ecthyma should be either banished from medicine, or they should be used simply as generic terms, to indicate the presence of a large number of pustules. They represent no distinct diseases."

How far the value of statistics of recoveries from pneumonia is disturbed by one single fact—the age of the patient—may be gathered from the results of pneumonia, as lately given in the returns from Salpêtrière. During March, there were 428 recoveries and 40 deaths from bronchitis in all the hospitals of Paris; and pneumonia in adults and the young was of a very benign character. But, amongst the aged women at the Salpêtrière, 12 out of 16 affected with pneumonia died. So also amongst old men at the Incurables. Of 17 patients attacked with pneumonia during the last three months, 10 died. M. Charcot remarks, that pneumonia does not attack those old people who are confined to their beds, but almost exclusively those who are able to go about. His opinion is, that most of the old people at the Invalides catch their pneumonia at the *lieux d'aisances*, which are much exposed. At the Hôpital des Enfants, during March, there were 8 cases of

croup, and 26 deaths. Under M. Roger, of 5 cases of croup, 3 were tracheotomised, and all three died; the other 2 recovered. Under M. Simon, there were 5 cases of croup; all were tracheotomised, and of these 3 recovered. At Necker, under M. Vernois, there were 4 cases of croup, all of which died, 3 having been tracheotomised. A woman suffering from phthisis, lying near the cradle of one of these children, contracted general diphtheritis; false membranes were found extending down to the smallest bronchial ramifications. Of acute rheumatism, there were 12 cases under M. Martin, all of whom had endocarditis; 8 under M. Gubler, 7 of whom had endocarditis, and the eighth pleuropneumonia. Erythema nodosum was observed in many of these cases of acute rheumatism. Of typhoid fever, there were in all the hospitals 33 cures and 15 deaths. The very high rate of mortality observed in these instances of acute diseases will strike the English reader. To what is it attributable?

DR. VIANI, of the Island of Réunion, tells us that, of all vermifuges, the best he knows is the juice of the *Larica papaya*. Santonine, he says, is used to an enormous amount in the island; but, for some reason or other, it often fails as a remedy. The milky juice of the papaya is a sure and infallible remedy. Some years ago, the children of every family in the island were wont once a year to take "papaya milk". When properly administered, moreover, it is a perfectly harmless remedy. It is a very ancient remedy, and may well be brought again into favour in all countries where the *Larica papaya* grows. So says Dr. Viani, in the *Répertoire de Pharmacie*.

The ages of the forty *immortals* who at present form the French Academy amount together to 2,611 years. There are amongst them five octo-, ten septua-, thirteen sexa-, eight quinqu-, three quadra-, and one trenta-genarians.

MM. Bergeron and Lemaitre have lately made some observations on the elimination of medical substances with the sweat. (*Arch. Génér.*) The patients were placed in a dry chamber, where the temperature could be raised to 60° and 65° cent. The sweat was then allowed to drain off: and as much as from forty to sixty grammes could be collected in this way. They found that the arsenites of potass and soda were eliminated as such. The arsenite of iron was decomposed, the iron passing away with the urine, and the arsenic as an alkaline with the sweat. The protiodide of mercury was eliminated as a bichloride: traces of mercury were found in the sweat; and the iodine was discovered in the saliva and the urine. Bichloride of mercury was also found in the sweat and in the urine. Iodide of potassium was found in the saliva and the urine, but not in the sweat. In two cases of albuminuria, albumen was not found in the sweat. A small quantity of sweat, collected from a diabetic patient, contained a large quantity of sugar.

Scientific Notes.

A NEW SYSTEM OF ELECTRO-MAGNETS WITH UNCOVERED WIRE.

An electro-magnet consists essentially of an iron cylinder covered with a helix of metallic wire, through which passes a current of electricity. Until now it has been supposed necessary to insulate the wire composing the helix by covering it with silk, cotton, gutta-percha, or some other insulator. M. Carlier, in a communication to the Academy of Sciences, states that he finds that the covering is not only unnecessary, but disadvantageous. By using an uncovered wire, but separating the layers of spirals one from the other by paper envelopes, the magnetic effects are twice as strong as when a covered wire is employed. (*Chemical News*.)

PULVERISATION OF PHOSPHORUS.

Blondlot has found that phosphorus may be reduced to a very fine powder by melting it in a hot concentrated solution of any neutral salt, or even of syrup, and shaking continually until cold. It has long been known that phosphorus was brought to a finer powder in urine than in water, and that effect was ascribed to the presence of urea. M. Blondlot shows that it is merely a consequence of the density of the liquid. (*Chemical News*.)

MALT AS FOOD.

The experiments of Mr. Lawes establish that the increase of live weight in animals fed upon malt is less than in those fed upon unmalted barley. In the case of cows, too, less milk was given by the malt-fed than by the barley-fed animals. The experiments of Mr. Lawes were very conclusive, and appear to have been very fairly conducted. (*Chem. News*.)

THE DEAD SEA WATER.

Mr. Simson gives an analysis of the waters of the Dead Sea, obtained by himself from a spot three miles or so west of the mouth of the Jordan. He confirmed from experience the statements of all travellers respecting its great buoyancy. It is impossible for the human body to sink in it. Having submitted it to the highest magnifying power under the microscope, he failed to detect the presence of the most minute infusorial life. The analysis was made by Professor Gardner. 1000 parts contain: Fixed salts, 232.800; water, 767.200. In 100 parts there are: Chloride of sodium, 8.81; chloride of potassium, 1.24; chloride of magnesium, 10.42; chloride of calcium, 2.10; chloride of aluminium (traces); bromide of magnesium, .29; sulphate of lime, .42—in all, 23.28 of saline matter; and 76.72 of water.

SPECIFIC GRAVITY OF SOLIDS.

M. Persoz describes the following method. A known weight P of the body, the density of which is desired, is introduced into a flask of known capacity, V , full of air. The volume of the body will be given by that of the air displaced; so fill up the flask with water, or some other proper liquid, and measure carefully the quantity required. The volume required, v , subtracted from V , will give the volume of the body; and the density will be the weight P divided by V minus v . (*Chemical News*.)

PRESSURE OF ICE THROUGH SMALL APERTURES.

M. Tresca finds that ice issues in exactly the same way as solid bodies (soft metals and ceramic pastes) from a small aperture when submitted to great pres-

sure. The jet is formed of perfectly distinct concentric tubes; which, however, in this case are grooved through their entire length with transverse fissures, which gave to the jet the appearance of being made up of washers arranged one after another. The results support strongly Dr. Tyndall's theory of constitution of glaciers. Some effects resembling moraines were, indeed, seen when coloured ice was employed in the experiments. (*Chemical News*.)

CONSTITUTION OF THE SUN.

Further observations with a more perfect spectro-scope have confirmed the opinion before published by Father Secchi that the atmospheric lines are due to aqueous vapour. With regard to the constitution of the sun, he observes that, on looking at it through M. De la Rue's eye-piece, the luminous base of the sun is seen as a net-work, over which a great number of white points are visible more or less elongated and separated by darker meshes, the knots of which appear to be small black holes. The white bodies, to which the shadows of the solar spots give a peculiar appearance, the author regards as masses of luminous clouds which certainly cannot be composed of aqueous vapour. (*Chemical News*.)

ACTION OF GYPSUM ON WINES.

M. Chancel has come to the following conclusions. 1. The gypsum takes into the wine in the shape of tartrate of lime half the tartaric acid which would otherwise remain in the marc. 2. It increases the acidity of the wine, brightens the colour, and insures keeping. 3. It introduces to the wine in the state of sulphate the greater part of the potash which would be found in the marc in the state of bitartrate.

RAPID ABSORPTION OF CRYSTALLOID SUBSTANCES.

Dr. Bence Jones has communicated instances of the extraordinarily rapid passage of some substances into the vascular and non-vascular tissues of the body. Lithium administered to a guinea pig eight hours before death was found in the crystalline lens. In another pig killed two hours and a-half after the administration, the presence of lithium in the cartilage of the hip was distinctly shown. In another animal, killed after an hour, it was shown faintly in the hip and knee, but in the aqueous humour of the eye very distinctly. It was also found in the crystalline lens and joint cartilages of human subjects who took lithia within a very few hours of death.

TEST FOR TARTAR EMETIC.

Claus points out that perchloride of iron causes a yellow coloration in a strong solution of tartar emetic; but in a dilute solution occasions a yellow precipitate, which seems to consist of a mixture of basic chlorides of antimony and iron and some tartar emetic. (*Chem. Central Blatt*.)

THE SCORPION.

The Academy of Sciences has received a paper from Dr. Guyon on the mortal effects of the African scorpion's sting. Its scientific name (*Androctonus funestus*) indeed expresses that it is fatal to man, and yet Dr. Guyon states that perhaps out of one hundred persons stung there is scarcely one that dies of it. The ancients, who under the name of scorpion certainly mean the same insect, since it is found represented on Egyptian monuments and even engraved on precious stones, had a much stronger opinion of its deadly effects. Lucan, in his *Pharsalia*, says, "Who would believe, on seeing the scorpion, that it has the power of causing such a sudden death?" Abd-Allatif, an Arabian physician, says, "At Koos abundance of scorpions are found, whose sting is frequently mortal."

Dr. Guyon knows of eight cases in which the sting of the African scorpion was followed by death; three of the sufferers were men, two were women, and three children.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFRESON, M.B. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S. Ed., Professor of Clinical Surgery in the University of Edinburgh.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
SOUTH MIDLAND. [Annual.]	George Hotel, Northampton.	Wednesday, June 7, 2 P.M.
NORTHERN. [Annual.]	Library, Newcastle- upon-Tyne Infirmary.	Wed., June 23, 10.30 A.M.

SOUTH MIDLAND BRANCH.

THE annual meeting of the South Midland Branch will be held at the George Hotel, Northampton, on Wednesday, June 7th, at 2 P.M.; GEORGE ASHDOWN, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, as soon as possible; or not later than the 23rd instant, to Dr. Bryan, Northampton.

JOHN M. BRYAN, M.D. } *Hon. Secs.*
G. P. GOLDSMITH. }

Northampton, May 13th, 1865.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

The Council of Management hope that gentlemen will prepare papers and cases, and forward the titles of the same to Dr. Philipson not later than June 17th. Dinner at 6 P.M.

G. H. PHILIPSON, M.B., *Hon. Secretary*.

THE YELLOW FEVER IN BERMUDA. By a general order issued from the War Office, Staff-Surgeon Major T. W. Barrow has been promoted to the rank of Deputy Inspector-General, and Surgeon F. Cogan (2nd Foot) to that of Staff-Surgeon, for highly meritorious services during the epidemic of yellow fever in Bermuda; and the conduct of Staff Assistant-Surgeons F. J. Shortt and F. Pennington and of Assistant-Surgeon R. Burland, M.B., Royal Artillery, is spoken of as having been conspicuous and praiseworthy.

Reports of Societies.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 16TH, 1865.

J. C. LANGMORE, M.B., President, in the Chair.

Infantile Paralysis. MR. WILLIAM ADAMS mentioned that he had frequently had to treat cases of the above complaint, and that in some instances he had been able to restore the power of locomotion, when it had long been supposed to have been irretrievably lost. Infantile paralysis, Mr. Adams observed, came on frequently during teething, at the age of one or two years; both arms or both legs were paralysed suddenly, or within a few hours time, or only one limb might be affected. Sir B. Brodie used to say that, unless this paralysis were naturally recovered from in six months, it was hopeless. In three to six months there was usually the greatest amount of recovery, the rectus muscle of the thigh being often the last to recover. As to the pathology of the disease, Mr. Adams confessed he knew nothing of it. The most recent German authors attributed the affection entirely to the muscles; and Rilliet and Barthez recorded only two *post mortem* examinations. In these, as well as in one made by Mr. Adams, no appearance could be made out to account for the disease. Children did not die of it, and thus the cause of the complaint was not investigated. If practitioners were aware of this fact, they would probably make the necessary examinations. It must be remarked that natural recovery of the muscular power may go on from six months up to three or four years, during which time a series of events takes place; namely, contraction of all the joints. Mr. Wilkinson had lately brought him a child with great contraction of the knee-joints. The muscles around the hip-joint were among the first to recover. A child was lately sent him from Clifton, between six and seven years old, which had never stood. It had contraction of all the joints, arms, legs, and trunk, and Mr. Adams was able to promise the parents that the child should walk in three months. Dr. Brown-Séquard had requested Mr. Adams to see a young lady aged seven, who had been crawling for more than three years, in consequence of paralysis of both legs; in three months this child was able to walk with steel supports. If a child could use the psoas and iliacus muscles, it could be made to walk, and this was the practical test. It should be laid on the floor on its back, and if it can draw up its knees, success is certain. With regard to treatment in the earlier stages of the disease, he had known counterirritation down the spine used, but the chances were that no treatment would do much good. When the child has paralysis with flaccid muscles, rubbing and warm clothing are useful. Galvanism of both legs in warm water is useful, although many physicians and surgeons disparaged the remedy, and said that it had been tried and found valueless. He (Mr. Adams) had two tin boots filled with warm water, in each of which one of the little patients' legs is put, and galvanism applied. Dr. Gull had written some valuable papers on galvanism in the *Guy's Hospital Reports*. The nutrition of the limb must, if possible, be maintained. Dr. Junod's boot for exhausting the air was once in much repute, but is now, perhaps, too much forgotten. A paralytic patient of his could always warm the paralysed leg in ten minutes with this appliance. This apparatus had no bad effects, but was liable to get out of order. It was doubtless a useful remedy in

these and other cases. In many cases of this paralysis the rectus muscle remained paralysed for life, and the leg swings; but this can be compensated for by aid of mechanical means, so as to enable the patient to walk.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 8TH, 1865.

ROBERT BARNES, M.D., President, in the Chair.

Specimens and Communications. Dr. TYLER SMITH exhibited a portion of a Dermoid Cyst, with teeth attached, passed *per rectum* from a lady who had for a year and a half previously evacuated by the same canal a quantity of hair.

A paper from Mr. ROUSE, of New Zealand, was read, describing peculiar Marks on the Neck of an Infant born before his arrival, and which had not been touched. There was much difficulty in getting the child to respire; and the marks were so similar to those made for the purpose of infanticide that, had not the mother been very anxious for a live child, and it was certain it had not been touched, and had not the thick coating of vernix caseosa been perfect, he should have put these marks down at attempts at strangling.

Mr. HARRIS exhibited a Deciduous Bag, with a small opening at one end, expelled some days before delivery at full term. There was nothing in or after the labour to explain its nature. As there was considerable difference of opinion as to its origin, Dr. Meadows and Dr. Graily Hewitt were asked to examine it and report.

Mr. ROPER read a short paper on Labour in Primiparous Women late in Life, in which he questioned the commonly received opinion that labour after forty-five years of age was necessarily or commonly difficult; and quoted Dr. R. Lee's cases in support. He believed that the soft parts which oppose the head were rather lax and wasted after the age mentioned, besides which the uterus acted with more vigour than in multiparæ at that age.

The PRESIDENT said he had recently read a paper by Dr. Matthews Duncan, in which it was shown that the weight of the child diminished in women who had passed the age of thirty. This circumstance would help to account for the comparative facility of primiparous labour at a late period of life.

The PRESIDENT showed a number of Outlines of Children's Heads, illustrating the changes of form imparted by various modes of delivery. They were made by running a pencil around the head laid on a sheet of paper; and, in some instances, correction was made by measurements of the diameters of the head by means of the callipers. In this way the forms the head assumed in difficult labour, terminated by forceps, craniotomy, and by turning in contracted pelvis, were strikingly manifested.

Dr. MEADOWS exhibited a specimen of Imperforate Bowel, in which the colon ended at about an inch from the anal orifice, to which it was connected by means of an impervious cord, the anus being itself perfect. Attempts were unsuccessfully made during life to reach the bowel by the anal orifice, and the child died on the twenty-second day after birth.

Dr. BATHURST WOODMAN read a description of a fœtus, delivered by Dr. Gayton, in which the anterior parietes of the abdomen were absent, the viscera being covered only by peritoneum; the anus and rectum were absent; the imperfect penis was divided. The bladder had no outlet except the urachus, which was still pervious. The rest of the organs were as usual, except that the foramen ovale was

closed by a membranous septum. The fœtus lived a few seconds after birth.

TWO CASES OF FACE-PRESENTATION IN THE MENTO-POSTERIOR POSITION: WITH REMARKS.

BY J. BRAXTON HICKS, M.D., F.R.S.

The author began by pointing out that *a priori* there was no anatomical reason which rendered it absolutely impossible that spontaneous delivery should be effected with the chin posterior in face-presentation, even within the range of normal pelvis and head, as represented by some authors. Quotations from the works of nearly all the English authors were given to show the variety of opinions upon the subject. Smellie's case delivered by the forceps was recited, with his opinions and advice upon the treatment of such cases. Two cases given by Professor Braun were quoted, in one of which the fœtus was delivered by the natural powers, and in the other by the forceps, the chin coming over the perineum first. The author supplied another case in which, after ineffectual efforts to alter the position, he delivered the child alive by the forceps, without any detriment to the mother. The chin appeared first, coming over the perineum. The child was large and the pelvis normal. He also gave another case, where the face descended partly exterior to vulva so readily that, although the chin made the anterior rotation at the last moment, it seemed highly probable that it could have been born by natural power, had rotation been difficult. The state of our knowledge of face-presentation was then summed up as follows:—That although in the majority of cases the chin rotates forward during the descent in face-presentation, whatever was the position it occupied originally, yet in some rare cases the chin passes through the outlet obliquely; while in others the rotation cannot be accomplished at all, either by nature or art. Under these circumstances, in some very rare instances delivery takes place spontaneously, though the greater number of this rare class require the use of the forceps; by means of which either the chin over the perineum, or the vertex beneath the arch of the pubis, might appear first. The author thought, from a consideration of the foregoing cases of Smellie, Braun, and his own, in all of which the children were born alive, that provided the chin could not be brought anteriorly, then the head should be brought down in the most practicable mode, chin or occiput first, and not necessarily with the occiput first, as recommended by Smellie.

The PRESIDENT signalled the value of this memoir as tending to give precision to, and extend our knowledge of, labour with face-presentation. His own experience had proved to him that such labours were not so uniformly favourable as was commonly taught. Difficulty might occur at two stages:—1. At the brim; in this case he deprecated the forceps and craniotomy, and recommended turning as giving the child the best chance. 2. In the pelvis; difficulty might arise here in the way indicated in the paper—viz., from the head retaining the position in which it entered the cavity. The proper rotation depended upon a due relation between the head of a *live child*, or one recently dead, and the pelvis. In Dr. Hicks's case the child was alive; it was, therefore, probable that the pelvis was large in proportion. In such a case he should not despair of turning if art or nature failed to rotate the chin. In cases of due relation of pelvis and child, birth with the chin posteriorly was almost impossible; for in proportion as the face descended, there was a rapidly widening base of a wedge, formed by the occiput bent back upon the child's trunk, which could not pass the pelvis.

Correspondence.

THE CHEMISTS AND DRUGGISTS BILL.

LETTER FROM SEPTIMUS GIBBON, M.B.

SIR,—This Bill is calculated to seriously affect the interests of the profession. Being called into existence by the following resolution of the Medical Council—"That a communication be addressed to the Secretary of State for the Home Department, drawing his attention to the present defective state of the law regarding the practice of pharmacy, under which any person, however ignorant, may undertake it; and expressing the opinion of the General Medical Council that some legislative enactment is urgently called for to ensure competency in persons keeping open shops for dispensing medicines, and for the compounding physicians' and surgeons' prescriptions"—and being strongly supported by the trade, there is every prospect of its passing into law. Some influential members of Parliament admit that they favour it because it will create a *body of men competent to treat "trifling ailments"*.

Now, as this kind of medical practice is probably the most remunerative, the Parliamentary Committee of the Metropolitan Counties Branch have felt it incumbent on them to try and prevent it passing into other than strictly professional hands. They have (through Sir Fitzroy Kelly) presented the subjoined petition to the House of Commons, and propose to try and get clauses giving effect to its prayer inserted in the Bill.

If other Branches and medical bodies take the same view, it would be well for them to petition the House, or make their views known to their representatives.

To meet the views of the Medical Council, I would respectfully suggest that they revert to the old plan of publishing the *Pharmacopœia* in Latin, which would effectually exclude the grossly ignorant and uneducated from compounding prescriptions.

I am, etc.,

SEPTIMUS GIBBON, M.B.Cantab.,

Hon. Sec. to the Parliamentary Committee.

13, Finsbury Square, E.C., May 17, 1865.

The following petition was on the 15th instant presented to Parliament by Sir Fitzroy Kelly.

"To the Honourable Commons of the United Kingdom of Great Britain and Ireland, in Parliament assembled."

"The humble petition of the Metropolitan Counties Branch of the British Medical Association, sheweth—That two Bills, entitled 'Bills to regulate the Qualifications of Chemists and Druggists', are now depending in your honourable House. That chemists and druggists are neither qualified by law nor competent by education to practise medicine. That injury to health, and not unfrequently loss of life, result from chemists and druggists undertaking the duties of medical practitioners. That the sale of patent, quack, and other secret medicines, has an injurious influence on the health of the community, more especially on the infantile portion of it. That the traffic in secret remedies, which is repudiated by the qualified practitioner, enables the unqualified pretender and the uneducated quack to victimise Her Majesty's subjects to an incredible extent, as well in person as in purse. Your petitioners, therefore, humbly pray that in the said Bill adequate provision may be made: 1st. For preventing the registered chemists and druggists from practising medi-

cine and surgery. 2nd. For preventing the sale of any patent, quack, or other medicine, unless a sworn certificate of its composition be lodged with the Registrar appointed under the Bill, or be otherwise made accessible to the public. And your petitioners will ever pray, etc.

"Signed on behalf of the Branch Association,

"CHARLES F. J. LORD, *President*.

"A. P. STEWART, M.D.

"ALEXANDER HENRY, M.D.

"SEPTIMUS GIBBON, A.B. and M.B.)

Hon. Secs."

NATURE AND TREATMENT OF FEVER.

LETTER FROM A. B. STEELZ, ESQ.

SIR,—The courtesy with which Dr. Murchison has received the criticisms I ventured to make upon some of his views on the subject of fever, encourages me to continue the discussion.

Referring to the use of mineral acids in typhus, Dr. Murchison says that "their beneficial action is undoubted"; and he adduces, as proof of the assertion, that "they have been recommended for this disease in all countries since the days of Forestus, Sydenham, Van Swieten, and Boerhaave. They have lately been highly praised by Huss of Stockholm; by Haller of Vienna; and by Drs. F. W. Mackenzie, Chambers, and Richardson, in our own country. . . . I have (he goes on to say) tried the mineral acids in many hundreds of cases during the last few years, and I believe them superior to any other method of treatment. . . . I have often observed marked improvement follow the commencement of the acid treatment, at whatever stage of the fever it was tried."

Now I ask, might not the old-fashioned routine plan of treating fever by giving the traditional saline or febrifuge mixture every four hours, be defended on quite as good evidence? Although I would not assert that mineral acids are, under all circumstances, useless in the treatment of fever, yet I think stronger and more satisfactory reasons are required to show that they "are superior to any other mode of treatment."

I have not of late years had the opportunities of careful systematic clinical observation enjoyed by hospital physicians; but my acquaintance with fever has chiefly been formed from the treatment of patients placed under the most unfavourable circumstances; namely, in ill-ventilated cellars and garrets, in over-crowded courts, without systematic nursing, frequently without any nursing at all; and where, from the necessity of the case, treatment has been reduced to as simple a formula as possible; and not a few instances have come under my observation where patients have passed through severe attacks of typhus without any medical treatment whatever—that is to say, without swallowing any drugs.

The mortality under these conditions has not exceeded the average death-rate assigned to typhus; in fact, it has been in some instances exceptionally low. This experience has left an impression on my mind that typhus is a disease which has a strong proclivity to recover; and that its progress and result are very little dependent upon medicaments of any kind, and certainly uninfluenced by specific treatment.

When, therefore, I hear of a remedy for fever, I am sceptical as to its value. When I am told of an agent which, from its ascertained action on the system, is adapted to regulate or control any one of the deranged functions which go to constitute a case of typhus, I can at once recognise the *rationale* of its use, and reasonably anticipate benefit from its employment.

For instance, I know narcotics produce sleep, and I am equally cognisant of a frequent condition of insomnolence in fever. Alcohol excites and sustains vascular action, which is often greatly depressed in typhus. Mercury, as an alternative, is known to be capable of restoring deranged secretion; and so on. But upon what principle are we to consider mineral acids superior to all these? What indication do they fulfil? If it be said that they act by neutralising ammonia, their repute rests upon a mere hypothesis; and leaves unexplained the result of treatment in which the ammonia theory is ignored and yet equal success is obtained.

To place the acid treatment on a sound basis, it appears to me that it is necessary clearly to establish the fact, that the essential cause of fever is an alkali susceptible of decomposition by the exhibition of acids; or, failing this, a careful and extended trial of this particular mode of treatment, under circumstances which would admit of a fair comparison with other methods.

I must disclaim any intention of depreciating the accuracy of Dr. Murchison's observations; neither do I assert that his views may not prove to be correct; but only ask for more convincing testimony before I can subscribe to their validity.

The varying conditions under which different practitioners pursue their observations may have more influence than we suspect in modifying their views of treatment. A most accomplished and experienced physician, Dr. Gairdner, tells us that milk is so essential in the treatment of typhus, that (quoting him from memory) he says that "treating fever with stimulants and without milk is a proceeding which he cannot understand." Now, this is just what I have been doing for some years, and apparently with the most satisfactory results. I am, etc.,

A. B. STEELE.

Liverpool, May 13th, 1865.

MEDICAL ETIQUETTE.

LETTER FROM EDWARD WATERS, M.D.

SIR,—In the JOURNAL of May 6th last, you published a communication from Mr. Thelwall of Farn-don, headed "Medical Etiquette", in which my professional conduct was assailed. As Mr. Thelwall imagined himself aggrieved, he would, I think, have himself acted more strictly in accordance with "medical etiquette" in applying to me, either directly or through a third party, for an explanation, instead of publishing an *ex parte* statement, and appending to it a hastily scribbled private note from me, without giving me any intimation of his intention so to act. Mr. Thelwall, however, having elected thus to submit the case to the members of the British Medical Association, compels me also to publish a statement of the facts. I could have wished that my rejoinder should have appeared with the original statement, so that the one might not be read without the other. Next, I had hoped to have been in time for last week's JOURNAL; but, not having received an answer from Mr. Eden in time to permit me to do so, I have been obliged to delay until now.

The history of my connexion with the case is as follows.

On Tuesday, March 14th, a servant called at my house with a message from Mr. Thelwall requiring my attendance, as soon as possible, on a case under his care. On arriving at the house where the patient was lying, I met Mr. Thelwall, and ascertained that the patient had been injured the day before by a fall off his horse while hunting, and, in addition to other injuries, had been unable to pass any water since the

accident. The bladder was distended, and Mr. Thelwall had attempted to draw the water off; but, owing to the calibre of the urethra being encroached on and much narrowed by an external bruise of the perinaeum, which caused swelling of the mucous membrane, it was impossible to introduce the catheter he was using, owing to its being too large for the passage. Finding the case to be a surgical one, I asked Mr. Thelwall if he had sent for me. He distinctly replied in the affirmative; made no allusion to having sent for any one else; and, until I saw his statement to that effect in the JOURNAL, I had no knowledge of his having done so.

Mr. Thelwall states that "Dr. Waters wished to see the patient again the same evening." Had it been otherwise, I should have been wanting in my duty to him. A warm bath had been agreed on as a palliative; but it is manifest I could not leave the patient till the following day with his bladder unrelieved, in addition to his other sufferings. That this might not happen, and feeling, the more I thought of the case, that there was no time to be lost, I, on due reflection, requested Mr. John Harrison, a consulting surgeon to the Chester Infirmary, to accompany me, lest his services might be required, and, at any rate, to bring the necessary instruments with him. I mentioned to Mr. Harrison that the case was mainly a surgical one, and that I wished to transfer it to him.

Mr. Thelwall further states that, "After examining into the case, they" (Mr. John Harrison and myself) "went to the other side of the room, and conversed together *sotto voce*." In thus acting, I was influenced by delicacy to Mr. Thelwall; but I can have no objection to inform him that I was then requesting Mr. Harrison to allow him the use of one of his catheters, which was accordingly done. I was desirous that Mr. Thelwall should thus retain the confidence of his patient, by showing that, when he had the appropriate instrument, he was equally able with another to succeed; and it was only on his failing to introduce it that Mr. Harrison drew off the water.

Mr. Thelwall then states: "They came the following day, and indeed continued their attendance until the death of the poor fellow on the Friday following." Mr. Thelwall himself suggested to me that Mr. Harrison should come out the following morning. The catheter used was then left for Mr. Thelwall to pass in the evening; but he again failed, and it afterwards necessarily devolved on Mr. Harrison to relieve the patient.

I may state for myself that, though acting as a physician, and not a surgeon, I had no alternative but to continue my visits, as the patient specially required me to do so; and, though the case resulted from an accident, it involved important medical features. I also forward you a letter from Mr. Eden, the retired surgeon referred to by Mr. Thelwall, who was an uncle of the patient, and who, with his sister the mother, watched him tenderly and unremittingly day and night; by which you will see that Mr. Harrison was the surgeon whose attendance the relatives expressly desired.

As regards the *post mortem* examination, I regret much that Mr. Thelwall did not witness it; but I really thought either his engagements or his possible indifference accounted for his absence. I wrote to him in the first instance, urging the propriety of it. He did not acknowledge my letter; but Mr. Eden called on me the following morning, and said that he had forwarded it to the father, and that, he doubted not, consent would be given. In anticipation of such consent, an arrangement was made to perform it the same evening, the following day being Sunday; and I left all arrangements respecting Mr. Thelwall to

Mr. Eden, who unintentionally omitted to inform Mr. Thelwall when it would take place; but he has declared to Mr. Thelwall that there was no desire to offer any slight to him on the part of any one.

I forward you a letter which I wrote to the coroner, who is a gentleman thoroughly able to enforce the respect due to his ancient and very important office; and I am happy to say he is satisfied no disrespect was intended to him. I am, etc.,

EDWARD WATERS,

Physician to the Chester Infirmary.

Chester, May 17th, 1865.

Mr. Eden writes, in his note to Dr. Waters:

"I can satisfy you, and, if it is desirable, Mr. Thelwall, that you were authorised by Mr. Charles Tomlinson's father to take out Mr. Harrison. I accidentally saw Mr. Thelwall on Monday, and reassured him that, so far as I was concerned, his not being called to the *post mortem* examination was an accidental oversight, for which I was sorry; and that it was not likely that you intended to slight him."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on May 9th.

Atherstone, Edwin, Grahams Town, Cape of Good Hope
Barton, Frederick, Bedford
Bate, George Paddock, Stone, Staffordshire
Berrill, Charles, Camberwell
Davis, William Frederick Pen, Ardwick, Manchester
Evans, Edward Charles, Cardiff
Gittins, John, Shrewsbury
Helsdon, Charles Victor, North Walsham
Hilliard, Henry Charles, Sharnford, Bedfordshire
Howells, Thomas, Kennington
Johnson, Thomas Soars, Wolverhampton
Leale, Josiah, Jersey
Mackinlay, James Grosvenor, Isleworth
Nuttall, William, Bury, Lancashire
Packman, Richard Young Vance, Ebury Street, Pimlico
Rickard, Frederick Martyn, Plymouth
Rowlands, James David, Carmarthen
Stuart, William Andrew Patrick, Barbadoes
Sutcliffe, William Greenwood, Ashton-under-Lyne
Twitcher, Thomas Nathaniel Parwick, Derbyshire
Verity, Abraham Robert, Bridgeton, Glamorganshire
White, James Atkin, Chatham Hill, Manchester
Willan, Thomas Henry, Auburn, Lincolnshire

At the same meeting of the Court—

Grigg, Joseph Collings, of Greenwich Hospital, passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College; his diploma bearing date April 12th, 1858.

Admitted on May 10th—

Barrett, Howard, Richmond
Bradley, John, Liverpool
Bryant, John Henry, Sussex Square
Colborne, Anthony Charles, Pimlico
Denziloe, William Le Gros, Bridport
Hilder, Nelson Albert, Camberwell
Holmes, Frank, West Gorton, near Manchester
Keall, William Powell, Bristol
Keall, John, Stratton, Cornwall
Leal, Thomas, Penzance
Leigh, Thomas Drake, Liverpool
Marsh, William Joseph, New Kent Road
Millett, George Bowin, Penzance
Nell, Richard Frederick, Cardiff
Pritchard, George Frederick, Highbury
Stone, John Neesam, Dublin
Visick, Clarence, Exeter
Wall, Joseph, London
Welch, John Burges, Taunton
Wilkins, John Canning, Pinner, Middlesex
Worsley, James Henry, Bluepits, near Manchester

APOTHECARIES' HALL. On May 4th, 1865, the following Licentiates were admitted:—
Bott, Charles Glen, Brentford

Fairles, Nicholas Watson, South Shields
Jones, William Griffith, Llanelly, Carmarthenshire
Jlewellyn, Rees, Maesgwyn, Breconsire
Strange, William Heath, Sreatley, near Reading
Treves, William Knight, Dorchester
Waymouth, Albert, Middlesex Hospital
Weld, Charles Humphrey, Rolvenden, Kent

At the same Court, the following passed the first examination:—

Cooke, George Richards, Charing Cross Hospital

Admitted on May 11th—

Allen, Josiah, Ripley, Derbyshire
Bostock, Edward Ingram, Horsham, Sussex
Covey, Charles Edward, Basingstoke
Evans, John Tasker, jun., Hertford
Fyson, Ernest Last, Exning, near Newmarket
Langley, John Thomas, Gansarew, Monmouthshire
Nuttall, William, Bury, Lancashire
Thomas, David Howell, Swansea
Watson, James B., Havant
Webb, George Fortescue, Dawlish, Devon
Whiting, Henry, Southend, Essex
Wood, Herbert, Ashton-under-Lyne
Wright, Jarvis, Knutsford, Cheshire
Wright, Morden, St. Bartholomew's Hospital

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH. (Double Qualification.) The following gentlemen passed their first professional examinations during the recent sittings of the examiners.

Affleck, James, Ayr	Kane, T. J., Galway
Affleck, John, Dumfriesshire	M'Laurence, H., co. London-
Alexander, J., Caithness	derry
Alcock, C., Nottingham	M'Rae, John, Ross-shire
Bates, Tom, March, Cambridge	Martin, T. F., co. Louth
Brayton, J. G., Cumberland	Naismith, Wm. J., Sultanpore,
Campbell, Donald, Perthshire	India
Clarke, W. H., Birmingham	Pattie, R., Dumfriesshire
Cote, W. N., Plattsburgh, N.Y.	Porteous, Jas. L. H. H., Had-
Cox, J. W., Annan	dingtonshire
Cribbes, H. S., Killin	Reynolds, E. J., Dublin
Farrelle, W. K., Longford	Robinson, J., Lancashire
Gilruth, G. R., Edinburgh	Sinclair, G. M., Haddington
Greene, R., Boston, U.S.	Stanley, W. E. S., Cumberland
Hamilton, A., Dundee	Unwin, J. B., Sussex
Hunter, W. C. S., Dundee	Waring, R. W., Cavendish
Jones, E. S., Carnarvonshire	Wyllis, W. E., Somersetshire

And the following gentlemen passed their final examinations, and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh.

Benson, J., co. Roscommon	O'Hara, C., co. Fermanagh
Burt, D. A., Fifeshire	Patchett, H., Lancashire
Burton, J., Walsall	Paterson, T., Mid-Lothian
Fothergill, J., Westmoreland	Raby, John, Cornwall
Godfrey, Frank, Salisbury	Shields, R., Edinburgh
Hickinbotham, J., Birmingham	Simpson, J., Cumberland
Johnstone, J., Liverpool	Smith, Henry R., Berwick-on-
Leman, Joseph, Buckingham,	Tweed
Canada	Smyth, Wm., co. Tyrone
Mackenzie, W. S., Sutherland-	Thompson, Wm. G. W., Bally-
shire	money
Mason, J. L., Montreal	Wotherspoon, John T. R., Dum-
Murray, G. B., Annan	friesshire

ROYAL COLLEGE OF SURGEONS, EDINBURGH. The following gentlemen passed their final examinations, and were admitted Licentiates of the College during the recent sittings of the examiners.

Anderson, J. K., Arbroath	Jameson, Robert, Ayrshire
Brakenridge, D. J., Perthshire	Knight, A. A. H., Berwickshire
Chiene, John, Edinburgh	Mackelvie, R. M., Wigtownshire
Denton, T. J., Yorkshire	M'Laren, R., Dumfries
Doyle, Bernard, co. Down	Skae, Frederick Wm. A., Edin-
Duncan, A. J., Bengal	burgh
Gibson, J. B., Ayrshire	Sydney, Henry, Kent
Glennin, Douglas, Dum-	Taylor, James, co. Antrim
friesshire	Thornley, J. G., Londonderry

APPOINTMENTS.

SCORESDY-JACKSON, Robert, M.D., appointed Physician to the Edinburgh Infirmary, in the room of Dr. Warburton Begbie.

ARMY.

BARROW, Staff-Surgeon-Major T. W., to be Deputy Inspector-General of Hospitals, for highly meritorious services during the epidemic of yellow fever in Bermuda.

COGAN, Surgeon F. 2nd Foot, to be Surgeon-Major, for highly meritorious services during the epidemic of yellow fever in Bermuda.

CROUSE, Surgeon-Major J. B. St. Croix, to be Staff-Surgeon-Major, vice D. Hanley, M.D.

HANLEY, Staff-Surgeon D., M.D., to be Surgeon 11th Hussars, vice Surgeon-Major J. R. St. Croix Crosse.
 MEE, Surgeon J., Royal Artillery, to be Surgeon-Major, having completed twenty years' full-pay service.

ROYAL NAVY.

ANDERSON, William (a), Esq., Surgeon (additional), to the *Asia*.
 ARCHER, Archibald L., M.D., Surgeon (additional), to the *Indus*.
 ASSH, William J., Esq., Assistant-Surgeon (additional), to the *Implacable*, for the *Sealark*.
 BEAUMONT, Robert W., Esq., Surgeon (additional), to the *Fisgard*.
 BELLAMY, George, Esq., Surgeon (additional), to the *Cumberland*.
 BREEN, Thomas J., Esq., Surgeon, to the *Caledonia*.
 COATES, Matthew, Esq., Assistant-Surgeon, to the *Caledonia*.
 COLAHAN, Thomas N. W., Esq., Assistant-Surg., to the *Impregnable*.
 EASTCOTT, James C., Esq., Surgeon (additional), to the *Excellent*.
 FERGUSON, Robert, M.D., Assistant-Surgeon (additional), to the *St. Vincent*, for the *Martin*.
 GODFREY, George H., Esq., Surgeon (additional), to the *Victory*.
 HATCH, Jeremiah A., Esq., Assistant-Surgeon, to the *Terrible*.
 HILSTON, Duncan, M.D., Assistant-Surgeon (addit.), to the *Victory*.
 LAUDER, Henry W., Esq., Assistant-Surgeon, to the *Gleaner*.
 MACDONNELL, Henry, Esq., Assistant-Surgeon, to the *Irresistible*.
 NOLLOTH, Edward, Esq., Staff-Surgeon, to the *President*.
 STEWART, James, Esq., Acting Assistant-Surgeon, to the *Sphinx*.
 STEWART, William H., Esq., Acting Assistant-Surgeon, to the *Caledonia*.
 SUCANE, R. K., Esq., Assistant-Surgeon, to Haslar Hospital.

MILITIA.

PHILPOTS, H. J., Esq., to be Surgeon Radnor Division of Royal Cardigan, Brecon, and Radnor Militia.

VOLUNTEERS, (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

CARMICHAEL, J., M.D., to be Assistant-Surgeon 1st Edinburghshire A.V.
 EDKINS, C., Esq., to be Honorary Assistant-Surgeon 24th Somersetshire R.V.
 KENDALL, T. M., Esq., to be Honorary Assistant-Surgeon 5th Norfolk R.V.
 MACKIE, J., jun., Esq., to be Assistant-Surgeon 7th Forfarshire R.V.
 NEWINGTON, A., Esq., to be Hon. Assistant-Surgeon 41st Kent R.V.
 NEWMAN, W., M.D., to be Honorary Assistant-Surgeon 5th Lincolnshire R.V.
 SANDERSON, A. M., Esq., to be Surgeon 1st Edinburghshire A.V.

BIRTH.

ANDREWS. On May 13th, at 1, Oakley Square, London, the wife of Henry Charles Andrews, M.D., of a son.

DEATHS.

BACOT. On May 16th, aged 7, Edmund Macdonald, eldest surviving son of Surgeon-Major Bacot, 89th Foot.
 BRIDGE. On April 22nd, at Bath, aged 56, Mary Were, wife of S. F. Bridge, M.D., of Wellington, Somerset.
 CUMMING. On May 8th, at Edinburgh, Jean, widow of Robert S. Cumming, M.D., Surgeon R.A.
 DAVIES, Sir David, K.C.H., M.D., at Lucca, aged 72, on May 2.
 HAMILTON, Charles T., M.D., at Windsor Terrace, Malda Hill, aged 51, on May 1.
 KINSEY, Robert B., Esq., Deputy Inspector-General of Hospitals, at Calcutta, aged 48, on April 1.
 KIRKPATRICK. On May 2nd, at Whitechurch, Shropshire, Elizabeth, widow of the late Edward M. Kirkpatrick, Esq., Surgeon.
 SMITH, Wm. Henry, Esq., Surgeon, at Southsea, aged 53, on May 5.
 STANLEY, John, M.D., at Belle Vue, near Whitehaven, aged 88, on April 28.
 THOMPSON. On May 5th, at Biggleswade, aged 19, Rose Nash, second daughter of John Thompson, Esq., Surgeon.
 VOSE. On May 15th, at Liverpool, Eliza Sarah, widow of the late James Vose, M.D.

SCARLATINA AT ALDERSHOT. Scarlatina is rife at the present time amongst the children in the camp at Aldershot.

HOSPITAL FOR WOMEN. Her Royal Highness the Duchess of Cambridge has signified her pleasure to become a patroness of the Hospital for Women.

A VACANT CORONERSHIP. Mr. Carr of Newcastle is a candidate for the coronership of South Northumberland now vacant. He has the full support of all his Newcastle brethren.

ROYAL SOUTH HANTS INFIRMARY. A new wing is to be added to the South Hants Infirmary. Mrs. Crabbe subscribes £2,000 for the purpose, in memory of her late husband Colonel Crabbe.

A GOLD MEDAL. At the meeting of the Dublin Pathological Society last week, it was announced that no essay for the medal had been sent in.

OUR CRIMINAL LUNATICS. There are at present 770 criminal lunatics in lunatic asylums, including 500 "patients" at Broadmoor.

A SPLENDID SALARY. The Town Council of Gateshead have appointed an officer of health. His salary is £25 *per annum*—i.e., about nine shillings and sixpence a week!

ROYAL COLLEGE OF SURGEONS. At a meeting of the Council on April 5th, Messrs. Adams, Annandale, and Agnis, received from the hands of the President the Jacksonian Prizes and special honorarium respectively awarded to them for the excellence of their essays.

CONSUMPTIVE PATIENTS IN MADEIRA. Dr. Stone informs the *Times* that a proposal has been made to him by Captain Erskine, Her Majesty's Consul at Madeira, to guarantee the maintenance and medical treatment of twenty consumptive patients during the coming winter, if the authorities of the Brompton Hospital will undertake to provide transport to and from the place.

CEREBRO-SPINAL MENINGITIS. Dr. Tweedie says of the cerebro-spinal meningitis epidemic he is satisfied it is a disease that in modern times, at least, has not been observed in this country. In all his large experience of fever at the London Fever Hospital he never met with suppurative meningitis, which is characteristic of the Dantzie epidemic, as a lesion in genuine typhus as known to us here.

CONVICTION UNDER THE MEDICAL ACT. A Justice of Peace Court at Aberdeen, had last week before them a case in which Frederic Adair, who addressed himself to a certain class of cases, was accused of advertising himself as M.D., F.R.C.S., without a title to do so. A witness said he had given the accused directions as to getting a diploma from Glasgow. One was produced purporting to be from the Metropolitan College, New York, conferring the degree of M.D. on Frederic Adair. After other evidence Adair was fined £5, with costs, £2:2, for using the letters F.R.C.S. without warrant.

DIETARY OF METROPOLITAN WORKHOUSES. Mr. Villiers said lately in the House of Commons that the dietaries in workhouses have been prepared by the guardians of the unions or parishes to which the workhouses belong. They are generally framed, according to the experience of the board of guardians, to suit the exigencies of their own union or parish. They are referred to the Poor Law Board, who require the opinion of the medical officer, as to the propriety and sufficiency of the dietary for the particular workhouse. They receive his report, and comparing the dietary with certain principles and rules with which they have been supplied by a very eminent scientific authority, and with the result of their own experience, they either sanction the proposal or suggest alterations. It has not been the practice of the Board to compare dietaries of different unions together, as they have never sought to bring about any uniformity in this matter. But a communication from an experienced and able medical officer in the metropolis has been made to the Board a short time since, directing the attention of the Board to the diversities which prevail in the dietaries of the workhouses of the metropolis, and the Board propose to cause an investigation to be made upon the subject, with the view of ascertaining whether any action can be taken in the matter with a beneficial effect.

ROYAL COLLEGE OF SURGEONS. We are informed that Mr. Arnott is about to resign the seats he holds as a Councillor and Member of the Court of Examiners of the College as well as his chair at the Council of Medical Education and Registration. For his successor as an examiner, Mr. Hilton is mentioned; for his seat in the Council, Mr. Turner, of Manchester, will offer himself; and for the manly and independent enunciation of his views on all college matters on the last festival of the Fellows there is no doubt his claims to a seat in the Council will be recognised. The retiring members of the Council are Messrs. Quain and Shaw, who will offer themselves for re-election. Mr. Arnott's resignation will bring Mr. Wormald in as President.

DEFECTIVE RAIN-FALL. Mr. Symons has drawn up some elaborate tables concerning the fall of rain during past years, and says:—"A careful consideration of this table has led me to the following conclusions—1. That the decreased fall of rain during the last ten years is a general and not local phenomenon. 2. That the decrease amounts to about one-twentieth part of the entire average fall. 3. That in the Eastern and Midland counties of England the decrease has been greater than in any part of the United Kingdom, and amounts to more than a tenth of the whole. I need not say that this falling off in our water supply, at a time when the requirements for it are daily increasing, is a matter of national importance, as well as one of very great interest to water companies and others who are bound to supply a given volume of water, and find their only source gradually failing them. We must hope that it is only a temporary fluctuation, and not the inauguration of a regularly decreasing supply; but it seems to me to warn us of the effect of recent extensive drainage operations to tell us not wantonly to run all our rain instantaneously into the sea, but to store it against periods such as last year, when the blessings conferred by the rain from Heaven were withheld for a time, and to myself it seems to say, 'Hasten on the collection of old records of rain-fall, and see if 100 years tell the same tale as the last half century.'"

ST. BARTHOLOMEW'S MEDICAL COLLEGE, 1864-5. The scholarships and foundation prizes have been awarded as follows. *Senior Scholarship in Medicine, Surgery, and Materia Medica*—W. L. Shepard, T. Cuddeford, and J. O. Adams. *Senior Scholarship in Anatomy, Physiology, and Chemistry*—W. J. Garrett, W. Square, and F. H. Haynes. *Wiz Prize*—H. Rundle. *Hichens Prize*—E. W. Berridge. *Practical Anatomy, Senior. Foster Prize*—H. C. Upton; F. H. Haynes, R. B. Moore, J. A. J. Timmins, J. Quick, W. B. Burn, F. H. Lovell, W. Square, W. H. Tattersall. *Practical Anatomy, Junior. Treasurer's Prize*—L. Newton; *2nd Prize*—C. Wade; J. Kirkman, E. B. Crowfoot, W. Thurston, E. Angove, H. J. Butlin, L. Clapham.

ROYAL MEDICAL BENEVOLENT COLLEGE. The thirteenth annual festival in connexion with this college was held on Saturday last at the Freemasons' Tavern; the Right Hon. Earl Granville, K.G., in the chair. Among those present were Sir Charles Locock, Mr. Scourfield, M.P., Admiral Burney, Mr. Ferguson, Dr. C. Hogg, Dr. Babington, Dr. Billing, Mr. Probert, and about 120 other members of the medical profession. After the usual loyal toasts had been honoured, Dr. Babington proposed "the Army, Navy, and Volunteers." Admiral Burney responded for the Navy, and Mr. J. L. Probert for the Army and Volunteers. In the course of his remarks Mr. Probert alluded to the eminent services which Mr. T. Wakley had rendered in connexion with the Volunteer medical department. The toast of "the Church," proposed by Mr. Scourfield, M.P., was acknowledged

by the Rev. G. Pocock. In proposing the toast of the evening the noble chairman dwelt upon the merits which the institution possessed, and the claims which it had upon all who desired to see suffering and affliction alleviated. The institution had been founded by those whose work was exceedingly laborious, and its success might be attributed to the earnestness and zeal which the friends of this excellent charity had displayed. There was, probably, no profession in which accident and chance exercised so large an influence as that of medicine, for while some of its members soon attained distinction and wealth, others, through no fault of their own, would remain in obscurity, still working for the good of their fellow creatures. No profession, therefore, had more claims for sympathy upon every class of the community. The noble lord stated that the trustees of the late Dr. Gilbert had decided upon devoting a considerable portion of his legacy to the benefit of the Medical College. Sir John Bowring and two others of the trustees had informed him that they had decided upon founding three scholarships of £50 each in connexion with the school. In acknowledging the toast of "the Chairman," proposed by Sir Charles Locock, Earl Granville expressed the satisfaction which he experienced at occupying the position of president of an institution which was calculated to confer so many benefits upon the distressed and suffering. The remaining toasts were "the Treasurer," proposed by the Chairman and responded to by Mr. Probert; the "Head Master," proposed by Dr. W. Carr and responded to by the Rev. Dr. Thornton; the "Honorary Local Secretaries," proposed by Mr. Probert and responded to by Dr. Ray; the "Press;" the "Stewards;" and the "Ladies." The subscriptions amounted in the course of the evening to nearly £1000.

THE CASE OF RICHARD GIBSON. The reply of the Poor-law Board to the report of Mr. Farnall on the case of Richard Gibson, goes very minutely into all the facts connected with the alleged ill-treatment of the deceased, and expresses their opinion that Dr. Craig, by failing to ascertain the personal condition of the deceased, and neglecting to order for him such articles of nourishment as he required; and that Mrs. Elson, by omitting to ensure proper attention to his personal comforts and cleanliness, have so gravely neglected their duties, that the Board would not be justified in permitting either of them to continue in the offices which they at present hold. The Board, therefore, request that the directors will communicate this decision to Dr. Craig and Mrs. Elson, and require them at once to resign their respective offices as assistant medical officer and nurse at the workhouse.

UNIVERSITY OF LONDON. On the 10th inst., the Chancellor held a meeting at Burlington House, for the purpose of admitting to degrees those who had passed the various examinations, and awarding certificates and medals. Earl Granville, who wore his robes as Chancellor, presided. The following graduates who had passed the examination for the degrees in medicine were admitted. M.D.: J. W. Hicks, St. Thomas's Hospital; J. U. Huxley, King's College; H. T. Lanchester, St. Bartholomew's Hospital; J. N. Miller, University College; W. Moxon, P. H. Pye-Smith (medal), and T. Stevenson, Guy's Hospital.—M.B.: P. Best, University College, first in medicine (scholarship and medal); T. Fairbank, St. Bartholomew's Hospital, second in medicine (medal), third in midwifery, and second in forensic medicine (medal); C. A. Hingston, St. Bartholomew's Hospital, fourth (ex.) in medicine, fifth in midwifery, and seventh in forensic medicine; H. L. Kempthorne, King's College, fourth (ex.) in medicine, fourth in

midwifery, and fifth in forensic medicine; J. H. Hooper, St. Thomas's Hospital, sixth (*eq.*) in medicine, and eighth in midwifery; F. Simms, King's College, sixth (*eq.*) in medicine, and sixth in forensic medicine; J. A. Nunneley, Leeds Medical School and Guy's, tenth in medicine, and tenth in midwifery; E. L. H. Fox, University College, first in midwifery (scholarship and medal), first in forensic medicine (scholarship and medal), and third in medicine; J. J. Phillips, Guy's Hospital, second in midwifery (medal); W. Carter, Charing Cross and St. Thomas's, third in forensic medicine, sixth (*eq.*) in medicine, and seventh in midwifery; E. Casey, King's College, fourth in forensic medicine, sixth (*eq.*) in medicine, and sixth in midwifery; E. Ludlow, St. Bartholomew's Hospital, eighth in forensic medicine, ninth in midwifery, and eleventh in medicine.—M.S.: J. H. Hooper, St. Thomas's Hospital, alone in surgery (medal). After presenting the diplomas, he delivered an interesting address, in the course of which he said that the University had lost Mr. Senior. They had also lost—though, happily, not by death—the services of Sir James Clark; and in mentioning his name he could not help referring to the unceasing exertions which he had made on behalf of the University in perfecting the medical curriculum. He believed that it was not a boast but a mere truism to say that these medical degrees were surpassed by none in the respect paid to them by the profession at large and by all who were competent to judge. He then said that a statement was put into his hands with regard to the appointment of a house-surgeon to an hospital. It appeared that candidates were invited to present themselves with an assurance that they would be chosen according to their recommendation and certificates. Several candidates appeared, and the result was that a gentleman who was most highly recommended as to general qualifications and character, but who had not obtained any honours further than the usual degrees, was elected, while one of our graduates, who had obtained high honours, with all the medical degrees, was rejected. There might have been excellent reasons for it; but on the face of the statement it appeared the distinction was that one was a communicant and the other was not a communicant, both being members of the Church of England and having the highest possible characters. He would ask whether it was to the interests of the poor wounded people in that hospital that such a test should exist?

TREATMENT OF THE INSANE. Dr. Clouston says in his last report of the Cumberland and Westmoreland Lunatic Asylum: "I last year protested against the system which was prevalent among the relieving officers of sending insane patients to workhouses previous to sending them to asylums. Many patients complained bitterly that they were sent to 'the union' before coming here. One woman says that at a workhouse, because she was sleepless and noisy, the sane inmates beat her severely with sticks. The forms of insanity in this asylum are not usually so acute as in the patients of a large city; but the depressed and suicidal cases are quite as numerous as in most asylums. One of them was a married woman who had the impulse to destroy herself so strong that though she knew what she was doing, and knew how wrong it was, she made many and persistent attempts to obey it. She wished to come to the asylum for her own security, and immediately she came within the building she felt so safe that her thoughts were entirely diverted to other subjects, and she never had a suicidal idea again. In a few months she returned to her home quite well, and has remained so ever since. In another case a man who

had tried to hang himself, and had been cut down, was sent in and never again manifested the slightest tendency to destroy his own life."

OPERATION DAYS AT THE HOSPITALS.

MONDAY......Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY..... Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY.... St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY...... Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY..... St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY. Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Robert Lee, "On Uterine Polyp"; Mr. Henry Lee, "On Amputation of the Leg by a Long Rectangular Flap"; Mr. C. Hunter, "On the Hypodermic Administration of Certain Medicines"; Dr. Wynn Williams, "On Tuberculosis."—Zoological.—Ethnological (Anniversary).
WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Hyde Salter, "On the Diagnostic Value of the Various Forms of Dyspnea."—Geological.—Linnæan (Anniversary).
THURSDAY. Royal Society.
FRIDAY. Royal College of Physicians, 5 P.M. Dr. Lionel Beale, "An Inquiry into the Nature of the Phenomena which constitute Inflammation."—Royal Institute.

TO CORRESPONDENTS.

* * All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

THE MEMBERS OF COUNCIL OF THE ROYAL COLLEGE OF SURGEONS who this year retire are—Mr. Arnott, Mr. Quain, and Mr. Shaw. Mr. Arnott retires, it is said, definitely; the others will in all probability offer themselves for re-election. The election comes off in July. If the country Fellows intend once again to bring forward a candidate, they should commence operations at once.

COMMUNICATIONS have been received from:—Dr. GEORGE JOHNSON; Dr. G. H. PHILIPSON; THE HOUSE-SURGEON OF THE ROYAL PORTSMOUTH HOSPITAL; THE SECRETARY OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH; Mr. R. J. ROGERS; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Dr. LUND; Mr. PARKER; Dr. E. WATERS; PROFESSOR SIMPSON; Mr. C. HUNTER; Dr. THORNBURN; Mr. STONE; Mr. JOHN WINDSOR; Dr. H. C. ANDREWS; Mr. FRED. MASON; Mr. JABEZ HOGG; Mr. CALLENDER; Dr. S. GIBSON; and Mr. HANCOCK.

BOOKS RECEIVED.

1. Small-Pox: how to Annihilate it; or, Observations on the Pernicious Consequences of Imperfect Vaccination, and on the necessity of re-Vaccination. By R. T. Lodge, M.D. Liverpool: 1865.
2. Surgery in Bengal: an Address to the Bengal Branch of the British Medical Association. By Dr. J. Fayer. Calcutta: 1865.
3. The Ninth Annual Report of the State of the United Asylum for the County and Borough of Nottingham. Southwell: 1865.
4. The Study of Science; and its Undue Neglect as a Branch of Education. By George Padley, L.R.C.P. Swansea: 1865.

Notes

ON

THE PATHOLOGY AND TREATMENT OF CHOLERA.

BY

GEORGE JOHNSON, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN TO KING'S COLLEGE HOSPITAL; ETC.

[Continued from p. 450.]

WITH reference to the hypothesis that the characteristic symptoms of choleraic collapse are caused by the loss of the watery constituents of the blood, we have next to inquire, *whether the symptoms of collapse are such as an excessive drain of fluid from the blood would be likely to produce.*

Now, what is the condition of a patient who has suffered a profuse drain from the blood, whether of water alone or all the blood-constituents? What is the effect of a copious hæmorrhage, of a profuse and long continued leucorrhœa, of prolonged lactation, of excessive purging, whether the result of disease or of medicine? Is not the condition of a patient who has been exhausted by such means, of the nature of syncope? There are a small and frequent pulse, a pallid skin, dimness of sight, and *tinnitus aurium*: these symptoms being much increased by the erect posture; and, in extreme cases, the head cannot be raised from the pillow, even for a moment, without the occurrence of syncope. For a patient in this condition to walk or stand, or even to sit up, is simply impossible. Now, there is something in the collapse of cholera which is essentially different from the mere exhaustion which leads to syncope. In fact, almost the only symptom which is common to the two conditions is the extreme smallness and feebleness of the pulse.

One great distinction consists in the remarkable blueness, coldness, and other symptoms indicating that during the collapse of cholera the aeration of the blood is greatly interfered with; while no such symptoms of obstructed respiration occur in ordinary cases of exhaustion from excessive purging. Another great and obvious distinction is this: that whereas a patient exhausted by a drain of fluid from the blood, and therefore verging on syncope, is unable to assume the erect posture without losing at once his pulse and his consciousness, a patient in the collapse of cholera, whose skin is blue and icy cold and whose pulse is imperceptible or extremely small and feeble, is often able to stand up without becoming faint, and even to walk a distance which must require a considerable amount of muscular exertion.

This is a fact alluded to by several authors; and no one can have watched cases of the disease without having observed the surprising amount of muscular exertion of which even a cold and pulseless patient is capable. It is scarcely necessary to quote authorities for this statement; but I will refer to one in illustration of what has been advanced.

Scott says (*Report on the Epidemic Cholera*, p. 24): "Instances are not wanting of patients being able to walk, and to perform many of their usual avocations, even after the circulation has been so much arrested that the pulse has not been discernible at the wrist." The same author states, in another place, when speaking of the effects of blood-letting (p. 58), "It is remarkable that, in a disease like cholera, syncope should be so rare a symptom." And, again (p. 28), "During the progress of this disorder, when the nervous energy seems to be almost annihilated, and the functions of the heart and arteries to be abolished, this symptom (syncope) is yet very rarely observed."

Another remarkable difference between the collapse of cholera and the exhaustion caused by an excessive drain of liquid from the blood, consists in the rapidity with which a patient often recovers from the former condition. As an instance of this, I may quote the following from Dr. Gull's *Report* (p. 135): "I have 'seen' (says Mr. Grainger) 'a man stand at his door on Wednesday, who on Monday was in perfect collapse.' And this observation, as Dr. Gull observes, is in accordance with the experience of others."

With reference to this remarkable feature of cholera, Twining makes the following statement (*Clinical Illustrations of the more Important Diseases of Bengal*, p. 20): "In cases not fatal, the progress of recovery is often almost as rapid as the accession of cholera; and if the disease be treated at the very onset, it is not uncommon to see a person well on the third day, after an attack of the worst symptoms, which had commenced with coldness and collapse, and who, if left without remedies, would probably have died in six or eight hours. *In these instances recovery seems almost as sudden and complete as in cases of patients who are resuscitated after suspension of animation from submersion in water.*" It is scarcely necessary to insist upon the fact, that no such instances of rapid recovery from extreme prostration consequent on a drain of fluids from the blood are ever known to occur; nor, from the nature of things, is it possible that a great loss of blood-constituents can be restored with such extreme rapidity.

The natural and obvious inference from these facts appears to be, that there is an essential difference between the condition of a patient who has been exhausted by a profuse drain from the blood, and that of one in collapse with cholera. It is, therefore, incumbent on those who maintain that choleraic collapse is due to the loss of fluid by the intestinal canal, to explain, if they can, the remarkable differences which have here been pointed out between the symptoms of collapse and those of ordinary syncope.

Our next inquiry shall be, whether the effect of various modes of treatment in the collapse of cholera affords any support to the theory that a drain of fluid from the blood is the essential or the chief cause of that condition.

[To be continued.]

HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

ST. GEORGE'S HOSPITAL.

CASES OF FRACTURE OF THE BASE OF THE SKULL:
WITH REMARKS.

By THOMAS P. PICK, Esq., Surgical Registrar.

FORMERLY fracture of the base of the skull was looked upon as an injury almost inevitably fatal; and it is only within the last few years that it has been shown that these cases, not only sometimes, but often recover. Two of the cases detailed below are given as exemplifying the good results which may follow this class of injuries, in cases where the diagnostic symptoms are sufficiently well marked as to leave no doubt as to the nature of the injury; and to these are added two others, one of which terminated fatally, in which the symptoms were not so well marked, and in which some doubt existed as to the real nature of the lesion.

CASE I. Thomas M., aged 18, groom, was admitted September 30th, 1864, under Mr. Hewett.

History. No very satisfactory account of the accident could be obtained, but it appeared that he was thrown out of a cart which he was driving. He himself had no recollection of the accident, and did not know whether he pitched on his head. He was insensible when picked up. He had not been drinking.

On admission, he was in a semi-comatose state, lying on his side and breathing quietly. He could be roused with difficulty; but evidently objected to it, and speedily relapsed into the same stupid state. He would answer questions when roused, though incoherently. There was no paralysis. There was no bruise or wound about the head, but there was bleeding from the left ear. No abrasion could be found about the external meatus. The pupils were natural and acted. Pulse 80, compressible; skin cold.

Oct. 1st. He was much more sensible than last night. He had passed a quiet night, but had been very sick. He now answered questions rationally, and asked for anything he wanted. Oozing of blood from the ear still continued. The pulse was 84, compressible, greatly accelerated when roused. The tongue was clean; the pupils natural. He was ordered three grains of calomel immediately.

Oct. 2nd. Last evening the pulse rose and became rather hard. He was bled to eight ounces. Afterwards he passed a quiet night, and this morning seemed comfortable, though drowsy and stupid. There was no more bleeding from the ear, but some appearance of a clear discharge on the pillow. Pulse 70, quiet, compressible; skin warm and moist; tongue clean. The bowels had acted.

Oct. 4th. He complained of more pain in his head. The tongue was furred and white. Pulse 76, soft and compressible. The discharge from the ear had quite stopped. A large tender swelling had appeared on the left temple. He was ordered to repeat the calomel at night, and to have a senna draught the next morning.

Oct. 6th. He still remained in a drowsy state; he appeared to wander considerably, and was constantly

crying out. He could be roused sufficiently to answer questions. Tongue furred: pulse 72. The mouth was drawn slightly to the right side. There was much oedema and swelling over the left temporal muscles; and the skin was red and acutely painful.

Oct. 7th. He was much more rational, and seemed altogether brighter and better; but he had been very restless all night and in great pain. Tongue furred; pulse 76, compressible. The oedema, swelling, and redness, had extended on to the face and down the side of the neck.

There was an indistinct feeling of fluctuation over the swelling, which was extremely painful. An incision was made into the tumour, and a small quantity of pus and a considerable amount of broken-down blood was discharged. On passing the finger in, the bone was felt to be exposed and roughened. The finger could be introduced to a very considerable extent under the temporal muscle. A poultice was ordered to be applied.

Oct. 8th. He was very much relieved by the incision, and had had a quiet night. There was less swelling and redness down the side of the neck. Tongue cleaner; pulse 80. Fish diet was ordered.

Oct. 9th. He slept well, and seemed quite bright and cheerful; he had quite lost his former drowsy appearance. Pulse 76; tongue still slightly furred. The swelling of the face and down the side of the neck had entirely subsided. The mouth was still slightly drawn to the right side. He complained of being deaf on the injured side.

He went on well till the 16th, when he complained of more pain, after having passed a very restless night. A large swelling was found above the left ear. This was opened, and a large quantity of pus and blood escaped. There was also discharge from the left ear. His tongue was furred; pulse 113; skin hot. He was ordered to repeat the calomel and senna.

The discharge from the ear continued till the 25th, when it ceased. The scalp to a great extent again became adherent to the bone; and he was discharged November 18th with one small sinus, which led down to exposed bone.

March 6th, 1865. He showed himself at the hospital. A small piece of necrosed bone had come away, and the wound was quite healed. He seemed quite hearty and strong.

CASE II. Thomas F., aged 21, butcher, was admitted November 1st, 1864, under Mr. Hewett.

History. A short time before admission, he was cleaning the windows on the second floor of a house, and, "missing his hold," he fell into the area below, pitching upon his head. He was insensible when picked up, and had no recollection of the accident.

On admission, he was sensible enough to answer questions and state the reason of the accident. When not roused, he lay on his left side, moaning and breathing heavily. He complained of his head "feeling queer." There was no bruise nor wound of the head. There was considerable oozing of blood from the right ear; and there was coagulated blood in the nostril. He was very deaf on the right side, and the mouth was drawn to the left side. The pupils acted naturally. The pulse was 72; the tongue clean.

Nov. 2nd. He was more conscious and rational, but drowsy. He complained of pain in the head. There had been continuous and very considerable bleeding from the ear throughout the night, and it still continued in small quantities this morning. Tongue clean; pulse 72, soft. He was ordered to have three grains of calomel at night, and a senna draught the following morning, and to take nothing but beef-tea.

Nov. 4th. The bleeding had now all stopped. He

was still drowsy, but in no pain, complaining only of numbness down the right side of face, and "tingling noises" in the right ear. He was still very deaf on this side, and the face was drawn to the left.

Nov. 5th. He had been very restless all night, and complained of intense pain in the head. There was a wild and vacant stare about the face. Skin hot; pulse 84, full; tongue furred. He was ordered to repeat the pill and draught.

Nov. 7th. He still continued to be extremely restless; did not sleep at all, on account of the great pain and singing in the head. The tongue was furred, and was protruded to the left side; pulse 64, full. The bowels had acted freely. He was ordered to have the head shaved and ice applied, and to take two grains of calomel twice a day.

Nov. 8th. He had had rather a better night, and was in less pain. Pulse 64; tongue furred; skin cool. The bowels had acted slightly.

Nov. 11th. The pain continued to abate; and to-day he thought he could hear a little better. Tongue very white; pulse 60, soft. He was ordered to repeat the pill every night.

Nov. 14th. He said that now the pain was only very trifling. He heard better, and the face was less drawn; he could now close the eyelid. Pulse quiet. He was ordered to have fish diet, and to leave off the pill.

Nov. 17th. The pain had entirely left him. There was still something, however, peculiar about his manner; he answered questions abruptly, and there was a vacant expression. Tongue clean; pulse quiet. He was ordered to have ordinary diet.

From this date he gradually improved; the face assumed its natural aspect; the deafness disappeared to a certain extent; and he lost his abrupt manner.

He was discharged December 3rd.

CASE III. Denis M., aged 27, labourer, was admitted November 25th, under Mr. Hewett.

History. He was discovered by a policeman lying in an area in a state of intoxication. He was supposed to have fallen down, but it was not known how long he had been there.

On admission, he was quite insensible and smelt of liquor. The surface of the body was warm; the pupils were contracted, but sensible; pulse 60, soft. There was a scalp wound about an inch long over the left parietal eminence, not going down to the bone. Soon after admission, he vomited a quantity of fluid strongly smelling of rum.

Nov. 29th. He had been constantly sick during the night. This morning he was to a certain extent sensible, but being in a drowsy state, and passed his urine and motions unconsciously. He complained much of his head. Pulse 84, fluttering; skin hot. The pupils were contracted, but acted. He was ordered to have three grains of calomel immediately, and broth diet.

Dec. 1st. He still lay in a sleepy state, taking no notice of anything or anybody; but he was more conscious; was aware when his bowels were going to act, and he answered questions rationally. There was total deafness on the left side, and the mouth was drawn to the right side. Pulse 64, weak and fluttering; pupils natural.

Dec. 2nd. He seemed much brighter, and began to take notice of surrounding objects. The deafness still continued. There was effusion of blood under the left optic conjunctiva on the outer side of the globe, passing back into the orbit beyond the view; no effusion into the eyelid. On telling him to close the nostril and mouth and blow up the Eustachian tube, no air entered the left tympanum, nor did any come out of the external auditory meatus.

On examination of the ear with the speculum, the

membrana tympani was found to be unimpaired, but to bulge considerably outwards.

Dec. 4th. He was now quite sensible. He complained of pain down the left side of the face, and giddiness. Pulse 58, very weak. He was ordered to take half a drachm of sal volatile in camphor mixture three times a day.

From this time he gradually improved; permanent deafness, however, continued, though the paralysis of the face disappeared.

He was discharged December 28th.

CASE IV. William S., aged 17, plasterer, was admitted January 23rd, 1865, under Mr. Hewett.

History. Half an hour before admission, he fell off a ladder a distance of fourteen feet. He was insensible when picked up, and had no recollection of the accident.

On admission, he was perfectly sensible and answered questions rationally. The skin was cool; pulse 100, full. The pupils were dilated, insensible. There was slight oozing of blood from the left ear. There was no wound or bruise to be felt or seen about the head. He was ordered to have five grains of calomel immediately, and beef-tea for diet.

Jan. 24th. He had passed a quiet night, and was quite sensible. All bleeding from the ear ceased soon after admission, and did not recur. Pulse 96, soft. The pupils were natural and acted. The tongue was clean. The bowels had not acted. He was ordered to have a senna draught.

Jan. 27th. He had gone on well till to-day, when he complained of having been in very great pain all night. The pain was confined to the left ear and left side of the face. This morning there was a little purulent discharge from the ear, and the pain had somewhat abated. Pulse 84, full; tongue white; skin hot. A linseed poultice was applied to the ear.

Jan. 31st. There were still discharges from the ear and pain in the head, though the pain was not so great. He complained of deafness on the affected side.

Feb. 2nd. He had passed a very restless night, and complained of very great pain, not only in the left ear, but across the vault of the skull. The tongue was furred. He had a most anxious expression of countenance. Pulse 102, very weak; skin hot. There was some loss of muscular power on the right side of the face. He was ordered to have a blister applied to the nape of the neck, and to have four ounces of brandy daily, and two grains of calomel to-night.

Feb. 4th. He slept all night and seemed better this morning. Pulse 60, weak. His appearance was less anxious. He still complained of great pain. The discharge from the ear continued.

Feb. 6th. He passed a quiet night. He said the pain was no better, and his expression was rather anxious. There was more discharge from the ear. Pulse 60, weak; tongue clean.

Feb. 7th. He did not seem so well; did not sleep last night. Pulse rather quicker, 72, quite compressible. There was more anxiety of countenance. He was ordered to have the third of a grain of morphia at night.

Feb. 8th. He seemed hardly conscious: was constantly wandering in his talk, and answered questions vaguely. He still complained of intense pain in the head. Pulse very quick and weak. He was ordered to repeat the anodyne draught immediately and at bedtime, and to have another blister.

Feb. 9th. He was quite unconscious. The breathing was laboured; the pulse very quick and running; the pupils were dilated and insensible. He died at 5 P.M.

POST MORTEM EXAMINATION. There was no sign

of external injury. The surface of the brain was slightly injected, and the convolutions on both sides were flattened. The ventricles were distended with sero-purulent fluid, and the septum lucidum was softened. There was about a tablespoonful of pus in the arachnoid cavity at the base of the skull. A quantity of the same fluid occupied the sub-arachnoid cavity, all about the pons and optic commissure. It also passed up the fissures communicating with the spaces at the base, and lay in considerable quantities in the median fissure of the cerebellum. The lining membrane of the ventricles appeared natural, but pus adhered closely to the choroid plexus. The fourth ventricle contained pus. There was a fracture of the base of the skull commencing on the left side of the cranium, about an inch above the petrous bone; it passed thence across the anterior aspect of that bone, and terminated close to the middle lacerated foramen, which was not penetrated. There was no displacement, nor any injury to the dura mater. The membrana tympani was lacerated. No other parts were examined.

REMARKS. The foregoing cases present several points of interest, and worthy of observation.

In the first two cases (Cases I and II), the symptoms were sufficiently well marked to leave no doubt as to the nature of the injury. The bleeding from the ear was both *profuse* and *continuous*; and this, conjoined with rupture of the membrana tympani, is sufficient to establish a diagnosis. On this Mr. Prescott Hewett is very positive. He says: "The bleeding, to be of any value to us as surgeons, must be of a serious nature; but this is not all, it must also, and mark this especially, continue for some time; and if, in addition to these points, you can also ascertain that the membrana tympani has been recently ruptured, you need no longer hesitate; and let the issue of the case be what it may, you can state with confidence that there is a fracture of the base running through the petrous bone." (*Vide Lectures on Injuries of the Head, Medical Times and Gazette*, vol. i, 1858, p. 445.) Hence it will be seen that the first two cases were clearly fractures of the base. Not so the other two; here in one case there was no bleeding, and in the other the bleeding was neither profuse nor continuous. We have then to look for other symptoms; and the symptom which ranks next to that of escape of some of the contents of the skull, is injury done to the nerves as they are emerging from the foramina at the base of the skull; and curiously enough this symptom was present in all four cases. In all of the patients under review, there was deafness and paralysis of the affected side of the face indicating injury to the seventh pair of nerves. It is evident, however, that these nerves may be injured without fracture of the base, or the portion of brain from which they take their origin may have suffered some lesion, and thus their functions may be destroyed; so that this symptom standing alone, does not afford us a certain means of diagnosis, and it behoves us to look further. In Case III the symptoms which, in conjunction with the paralysis, determined the diagnosis, were twofold. First the state of the tympanum, which was proved to be full of something; and from the history of the case, we were justified in asserting this something to be blood; and secondly, the effusion of blood under the ocular conjunctiva, and moreover, this effusion extending back into the cellular tissue of the orbit beyond our sight. This, therefore, must have been a most extensive fracture implicating both anterior and middle fossa; and the only thing required to make it a complete case, was a rupture of the membrana tympani; this remaining entire, threw some obscurity over it.

With regard to the fourth case (Case IV), the symptoms were extremely obscure, and had it not been that the boy died and a *post mortem* examination revealed the state of the injury, the diagnosis must ever have been uncertain. True it is that he had bleeding from the ear, but this bleeding was neither profuse nor continuous; "there was a little oozing which soon stopped," so that this symptom was of little value. In the same way, though he had paralysis of the seventh pair, this symptom by itself was of little value, since it was argued that there might have been some injury done to the external ear, which in the first place had caused the hæmorrhage; that that injury had set up inflammation, which had extended through the bones to the membranes of the brain, causing inflammation of the latter, and on its way implicating the portio dura and portio mollis as they pass through the bone.

Thus there were no certain symptoms to found an opinion; and none was attempted, as it is far better in such cases to find a fracture when not anticipated, than to be reproached with having diagnosed a fracture which never existed. It is remarkable how often the symptom of paralysis of the seventh pair of nerves is present in these cases of fracture of the middle fossa of the base of the skull. On referring to my note-book for the last two years, I find a record of thirteen well marked cases of fracture of the base, and in ten of these this symptom was present. Of these ten, the symptom did not come on for some time after the accident; in eight, the period varying from two to six days; in the remaining two, the symptom was present when the patients first came under observation. The state of the pupil was a symptom formerly much relied on; but, from an examination of the thirteen cases under review, this sign is shown to be most untrustworthy. In six cases, the pupils are reported as natural, and acting under the stimulus of light; in three, the pupils were dilated, but sensible to light; in two, they were dilated and fixed; and in the other two, they were contracted, but acted.

Another point of interest in connection with these cases is the extreme variety of cerebral symptoms which they present in some, symptoms of a severe nature presenting themselves; in others, a total absence of all cerebral disturbance being observed; so that the presence or otherwise of these signs is not to be depended on. One symptom, however, is pretty constant, and that is the presence of concussion; it was observed in all of the thirteen cases. But it may be said that an injury sufficient to produce a fracture of the bones of the skull, is sufficient to produce a jarring of the brain; and this is undoubtedly true. Hence, we meet with cases in which the most extensive and severe injury has been done to the brain without any fracture of the bones; and, on the other hand, we find cases where the base is fractured without any visible injury to the brain. It has been stated above, that cases of fracture of the base of the skull are not so fatal as was formerly supposed. Of the thirteen cases, embracing all that have been admitted into St. George's Hospital during a period of two years, five proved fatal; in three, death occurred from laceration of the brain; in two, within forty-eight hours of the receipt of the injury, and in the other, on the fourth day; in the remaining two, the fatal result was produced by inflammation of the membranes; so that, provided there be no symptoms to indicate any serious lesion of the brain-substance itself, we are justified in giving a favourable, though, of course, a somewhat guarded prognosis.

The treatment in these cases appears to consist in keeping the patient in perfect quietude and on low diet, and carefully waiting and watching for symp-

toms of inflammation of the brain or its membranes. Should these symptoms arise, the pulse is the best index for treatment. On reference to Case iv, it will be seen that the patient was treated with stimulants from the first; but it will also be seen that his pulse was weak, and after the first day never over sixty, until just before his decease, when it mounted rapidly. Should, however, the pulse increase in number and volume, as in Case ii, small doses of calomel and counterirritation are the remedies; but it appears that these patients bear the administration of mercury less well than cases of the idiopathic form of this disease. The quantity, however, must be regulated by the state of the pulse.

Original Communications.

ENTOPTICS:

OBSERVATIONS ON THE RELATIVELY GREATER FREQUENCY OF MYODESOPSIA IN THE MYOPIC EYE.

By JABEZ HOGG, Esq., Assistant-Surgeon to the Royal Westminster Ophthalmic Hospital, etc.

[Concluded from page 507.]

The pearly and watery spectra are invariably associated with the earliest symptoms in nearly all affections of the conjunctivæ. The student sitting late and long over his books or microscope; the astronomer at his telescope, after long hours of night watching; the barrister and lawyer; are all, sooner or later, warned to desist by various troublesome spectra which confuse and dim the sight. Another class of sufferers from *muscæ volitantes* are those whose occupations make increasing demands upon the organ of vision. Intently occupied, it may be, in a badly-lighted and ill-ventilated room, and in a bent and constrained position, for many consecutive hours. An example or two of this class will serve to show the kind of annoyance usually experienced by them.

A gentleman, constantly engaged as a draughtsman, suffered for some time from spectra, which increased to such an extent, that after two hours at most he could proceed no longer with his work. A complete blur or black blot settled down over certain portions of the drawing, chiefly taking the form represented in fig. 10. If the day were cloudy, or the

Fig. 10.

general health at all disturbed, they were much more troublesome; and always appeared to move in the horizontal plane. When walking the spectra took other forms; generally some six to ten feet in advance and above the line of vision, and looking like groups of pearly drops. Upon raising the head, they

then had all the appearance of a cluster of stars or crystals, represented in fig. 11. Apparitions of the lacrymal fluids were nearly always visible, and espe-

Fig. 11.

cially so after long fasting or fatigue; but much less troublesome when walking in a brilliant sunshine. At times, he thought rain was falling before him, each drop being surrounded by a bright halo of colours; then, again, descending more slowly, gliding, as it were, before the pupil, as represented in fig. 12.

Fig. 12.

As this gentleman required only the occasional use of concave glasses for distant objects, it may be assumed that the spectra most annoying to him were in a great measure due to rays of light falling upon the retina in a state of dissipation.

Another illustrative case was that of a law-writer, also myopic, who, after days and nights of great fatigue, being at the time employed in the preparation of Parliamentary papers, became the subject of most annoying pearly and watery spectra. These were at one time associated with the more alarming symptoms of paralysis of the retina; insensible portions of which caused a partial obliteration of all objects. Letters and words were completely broken up, and occasionally quite blotted out; and when the head was thrown up, watery spectra fell over the sight like jets

Fig. 13.

of spray from a fountain; or at other times resembling branches of trees covered with snow, as in fig. 13. Compare this with the good bold Roman

type near, and the defect will be at once understood.*

A tutor, myopic from childhood, after a long and anxious period, arose one morning from his bed to find the sight of his right eye nearly blotted out. A peculiar and dense black cloud appeared to hang over every object, and he could but just perceive a small portion of the window. This cloud is represented at B (Fig. 14). Upon suddenly closing both

Fig. 14.

eyes, a number of spots darker than the cloud appeared to fall over the centre of vision. In a very strong light, he could just discern his hand, if held very near to the outer or temporal side of the head; but not so if placed directly before the eye. The black cloud partially disappeared when he assumed the upright position; but upon walking, a cloud not quite so dense moved directly before him. In the left eye, at the same time, pearly spectra appeared, which gradually expanded into a spider-like body, seen at A (Fig. 14). This followed the motion of the eyeball from right to left or upwards and downwards; but the densest part was always more in the centre of the pupil than shown at A. After a few weeks of medical treatment and perfect rest, some improvement began to manifest itself. While he was lying on the couch one day, a dark-looking fluid, "as black as ink", appeared to flow from the ovoid body situated at the top of the diagram B. On another occasion, it was all transformed into the jagged figure at C; and on stooping down and rather suddenly raising the head, it expanded into the curious looking body seen at D. The space on each side was always a perfect blank; doubtless insensible portions of the retina. The most marked improvement occurred while out walking in a clear bright atmosphere, when nearly all the spectra somewhat suddenly vanished from before both eyes. The right eye had several relapses, but sight slowly returned; and when last seen, he could read without producing fatigue either Greek or German; he could also see distant objects quite clearly, when he used glasses which neutralised the myopia. It was expected by his medical attendant that the retina had become detached in the right eye; but upon making an examination with the ophthalmoscope, an advanced staphyloma posticum,† a few

small, dark, scattered bodies in the vitreous humour, and an anæmic retina, were the changes discovered; so that to insensibility of the retina must we ascribe most of the distressing symptoms in this case.

Sir David Brewster, whose attention was early directed to these phantoms, in consequence (as he tells us) of the annoyance he experienced in his own eyes, observes of them "that, as they exist in all eyes, whether young or old, they are neither the result of disease, nor do they indicate its approach." This opinion Brewster afterwards qualified; and stated that, although some of the phenomena of *muscæ* may be seen by persons of all ages, and with the best eyes, "those which are more peculiarly entitled to the name, are exceedingly common beyond the middle period of life."

On the other hand, we know that opinions are still a good deal divided on this question. The older writers, as Pitcairn, Boerhaave, Plenck, and others, regarded all spectra with alarm; and believed that they were always indicative of retinal disease. De la Hire said "that only presbyopics were troubled with *muscæ*". The Royal Academicians of Paris added, that myopes are not more exempt from them than presbyopes. Wardrop says, "Short-sighted people are least liable to this affection". Donders has satisfied himself, both entoptically and microscopically, that, as age advances, *muscæ* float about in all eyes; but "that myopes are more troubled with them than others."* Dr. Mackenzie writes of them, "Certain it is, that the pearly spectrum is recognisable by all eyes, when sought for through a pinhole or through the eye-glass of a compound microscope. Yet eyes of normal conformation are seldom subject to *muscæ* (*myodesopia*). On the contrary, when a person complains much, he will always be found either myopic or presbyopic, or perhaps one eye will be myopic and the other presbyopic." This passage has been somewhat unfairly assailed; and, therefore, Dr. Mackenzie has endeavoured to make his meaning clearer: stating that (so far as he has been able to judge from a most extended practice) "eyes of normal conformation are seldom subject to *muscæ*; and, when a person complains much of *muscæ*, we always find him either myopic or presbyopic."

I have met with several persons, whose eyes were emmetropic, and possessed unimpaired power of accommodation, who nevertheless complained of *myodesopia*; and, therefore, I can go thus far with Sir David Brewster and others, in saying that sufferers from "*muscæ*" are not necessarily myopes or presbyopes. Dr. Mackenzie, however, complains that it should be said that he alleged as a reason why only myopic or presbyopic eyes are subject to *muscæ*, that "an accurate refocalisation of light issuing from external points upon the retina prevents their being projected thereon." But he denies that he ever said this; and gives the following as his opinion, that "the interception of the rays proceeding from external objects by filaments in front of the retina, or

* "Peculiar phenomena may be produced by these groups of scotomata, thus I have seen cases in which very small print was more easily and more quickly read than a larger one, because of the latter a whole word was never seen at once, and letters still larger were only partly visible. The glimmering usually complained of is entirely due to the fact, that in slight movements of the eye the letters form their images alternately on sensitive and insensitive parts, and thus each time come and disappear, sometimes with change of form, according to irregular displacement of the perceptive elements." (Donders, *op. cit.*)

† "Ophthalmoscopic investigation has shown that almost without exception, even in moderate degrees of myopia, changes, especially in the choroid, are to be observed; and it has been further found, that these changes are the expression of atrophy of the choroid, which, combined with atrophy of the sclerotic, is, as well as the latter, dependent on a distention of the posterior part of the eyeball. *Myopia* and *staphyloma posticum* have become nearly synonymous." (Donders, *op. cit.*, page 351.)

* "In the circles of diffusion of smaller surfaces of light, they exhibit themselves with extraordinary distinctness; and in general, the more diffuse uniform aspect of the objects is a condition under which they appear more distinct. In non-myopes, they are seen, indeed, also mostly on uniformly illuminated surfaces, while no other forms are depicted on the retina. Therefore, too, myopes find a diminution of this symptom from the use of concave glasses, which remove the uniform diffuse appearance of objects. But often the complaints continue, especially when the patients are uneasy about the symptom, and have once accustomed themselves to attend to it. I have seen instances in which anxiety about *muscæ* volitantes amounted to true monomania, against which all reasoning and the most direct demonstrations were in vain. This is especially the case when morbid changes in the vitreous humour have supervened. We must admit the existence of morbid changes as soon as we can with the ophthalmoscope perceive turbidities in the vitreous humour. And to these a real pathological importance is to be attached." (Donders, *op. cit.*, page 351.)

even the formation of magnified shadows by diffraction, produces comparatively little effect when the remainder of those rays are brought accurately to focal points upon that membrane. As I think, almost every one will perceive I mean 'comparatively little effect' upon the percipient organ."

This is certainly a very different statement from that contained in the quotation complained of; the one being the positive assertion of a supposed fact, involving an absurdity in reasoning upon optical effects; the other a modified statement which does not imply absolute contradiction of a well known fact. For the assertion that "comparatively little effect" is produced, does not amount to a denial that any effect is produced; on the contrary, it is an admission that some effect is produced, and that is all that is needed to render Dr. Mackenzie's assertion on this point compatible with the experience of other observers. Accidental circumstances, such as overwork of eyes or brain, as I have already shown, doubtless renders the perception of all muscæ greater and more annoying; and the indistinctness of images of external images in the case of either myopic or presbyopic eyes must, to a certainty, favour these distressing appearances and render them more perceptible.

One other illustration fully establishes the fact that, by neutralising the myopia, a marked diminution of the myodesopia takes place; the muscæ volitantes are (as Dr. Mackenzie says), "to a certain extent, extinguished in perfect vision", i.e., by a brilliant light, or by glasses which neutralise the myopia. Fig. 15 represents the field of vision of the left eye

Fig. 15.

on a dark winter's day when the eye was directed towards a lightish part of the sky. The band A A is a floating portion of lacrymal fluid passing slowly over the cornea. B is a similar band, with pearly globules. From c to c are images of fibres in the vitreous humour. Near d is a group of pearly beads, very indistinctly seen, when compared with those on the band B. Near E is seen an anæmic portion of retina.

Fig. 16 represents the field of vision of the left eye precisely under the same conditions of light as the

Fig. 16.

former fig. 15; but furnished with an appropriate glass to correct the myopia. In this diagram, it will be observed that one of the floating bands of fluid is

very faint; the other has quite disappeared from view. The fibres in the vitreous humour and the anæmic portion of retina are still visible; but several of the loose beads are no longer seen, and others become much fainter.

Fig. 17 represents the field once more of the left eye when directed toward the sky illuminated by a

Fig. 17.

brilliant sunlight. In this very bright light, although the sight was quite unprotected, the images became fewer, and almost wholly confined to the anæmic portion of the retina, the deeper fibres in the vitreous humour, and to a very slight and fragmentary portion of the lacrymal fluid, much less distinctly seen than delineated at A.

Fig. 18 again represents the field of vision assisted by a concave glass, and directed to a clear sky under

Fig. 18.

the same conditions as the former figure; namely, a brilliant sunlight.

So much for a good clear light and appropriate spectacle-glasses on the visibility of some muscæ. But I have found muscæ liable to be affected to a much greater extent by internal than by external circumstances; by only a slight derangement of health during a period of fatigue or overwork of the brain and eyes. As an instance of this, I give the field of vision of this gentleman after a period of prolonged anxiety and study.

Fig. 19 represents the left eye. The "veils" are very numerous, and merge so much into each other,

Fig. 19.

that it is difficult to say where one breaks off and the other commences. The fibres in the vitreous humour are numerous and very distinctly seen; the anæmic portions of the retina are two in number; the groups of beads larger and more numerous; in short, the

whole field of vision is peopled with entoptical spectra. In this condition, no glasses of any form appeared to diminish the number of spectra, lessen the inconvenience experienced, afford rest, or assist the sight in the least degree more; but when, after a period of rest and sleep, glasses were again tried, then a considerable diminution of the *visio phantasmatum* invariably resulted.

BATH AND BRISTOL BRANCH.

ENUCLEATION OF THE EYE.

By FREDERICK MASON, Esq., Bath.

[Read December 1st, 1864.]

THE attention of members of the Association was directed to this subject by a leading article in the JOURNAL of November 5th; and, as the question may arise as to the proper treatment to be adopted in a certain class of cases, I have considered the following may not be uninteresting, and may lead to useful discussion.

Judging from the records of the Bath Eye Infirmary, the operation of enucleation of the eye has not been a frequent one; for, on examining the case-books for the last fourteen years, I can only find an account of two eyes removed for disease arising from traumatic causes, in addition to two which have occurred during the present year.

I have not included those removed on account of malignant disease; but have confined myself to those cases where one eye has begun to suffer—the other having been lost by some wound or injury. The first two are from the case-book of the late Mr. Boulton.

CASE I. George Best, aged 37, a labourer, was admitted an in-patient of the Infirmary on September 6th, 1859, suffering from low traumatic ophthalmitis. He was dismissed on October 1st much better. On October 25th he was readmitted. As soon as he had been out a few days, all the symptoms returned, and it was determined to remove the eye to save the other, which was beginning to suffer. The eye was removed by Mr. Boulton. No difficulty occurred, and he was discharged with the right eye good, on November 7th.

CASE II. Samuel L., aged 37, a labourer, was admitted on January 23rd, 1860, suffering from traumatic loss of right eye. He lost his right eye by a blow from a stone two years previously, and the same globe had always been painful and irritable since. The left eye began to suffer, and it seemed necessary that the injured globe should be removed.

Jan. 28th. Mr. Boulton extirpated the right eye.

Feb. 4th. He had done remarkably well, the left eye improving daily. He was discharged.

CASE III. J. W., aged 47, a shoemaker, was sent to the Infirmary from Frome, on January 28th, 1864. He stated that, five years and a half ago, when chopping wood, a splinter entered the left eye, and destroyed vision. This eye is now shrunk and hard, and the cornea is altogether wanting. In the winter of 1862 and 1863, he found the sight in the right eye failing, but recovered during the summer. Six weeks ago, the sight again began to fail, and became worse so rapidly, that he had no useful or distinct vision, and was unable to distinguish the largest type.

The eye (the right) had a very dull hazy look. On examining it with the ophthalmoscope, the light did not penetrate to the fundus, and the reflection from the choroid was of a dark, reddish-black colour. Believing the remains of the left eye to be the source of

all the mischief, I did not hesitate to recommend him to submit to its removal; and, accordingly, on the 30th, he was placed under the influence of chloroform, and the eye was extirpated. Immediately after the operation, severe vomiting came on, but ceased soon after he was in bed.

Jan. 31st. He had passed a good night, and was doing well.

Feb. 3rd. The sight of the right eye was already very much improved, and he could read distinctly without the aid of a glass (he had previously worn spectacles) a text of scripture in large type fixed against the wall of the room.

Feb. 9th. He was discharged.

A fortnight after he left the Infirmary, he wrote to the matron, and said he had that day worked for four hours, repairing shoes; and he had no doubt that he should, in another week, be able to do a full day's (twelve hours) work.

Before bringing this case before you, I was desirous of knowing this man's condition at the present time. I therefore requested the matron to write to him. The following is an extract from his letter, dated November 21st, 1864.

"I did not try to work till a fortnight after I came home; the first day I could work but one hour; the next day about two and a half hours; the next day four hours; and within a fortnight, I could work twelve hours a day; but now I could work twenty hours a day if I wished to. Where there is good light, I can see to read the newspaper without glasses for a short time, but I generally use them for reading, but not in work."

CASE IV. John C., aged 37, a labourer, on April 23rd, 1864, was sent from Malmesbury to the Infirmary. He stated that, twenty years ago, the left eye was wounded with a piece of glass, and the sight was lost—probably from traumatic cataract. This eye remained quiet and without pain until two years ago, when he received a blow on the temple. The eye now became inflamed, and there had been constant pain ever since. He was on admission suffering intensely, not only in the eye but over the brow, which prevented him from either working or sleeping. The eye was congested, the cornea semi-opaque, with a large central portion perfectly so, and yellowish in colour, with commencing sloughing. Against this an opaque lens appeared to be resting. The right eye was weak, and constantly suffused with tears; and the tension was much greater than natural.

On April 24th he was placed under the influence of chloroform, and I removed the left eye. On dissection, the anterior chamber was found to be obliterated in consequence of the iris being firmly adherent throughout to the cornea, and to the capsule of the lens. The pupil was somewhat dilated, with the lens pressing forward through the opening. The lens consisted of a soft flocculent mass. The sclerotic, choroid, and retina, were all agglutinated and undistinguishable.

April 25th. Shortly after the operation all pain ceased, and he slept well through the night.

April 28th. He had had no return of pain.

May 5th. He had done well. The right eye continued to feel weak, if exposed to a bright light. He was discharged.

Since this man returned home, I have not seen or heard from him, excepting indirectly through other patients that he was able to keep to his work.

In neither of these cases was there any hemorrhage or constitutional disturbance after the operation; the after-treatment consisted in simply keeping a piece of lint wet with cold water over the eyelids,

and the men were kept in bed until the middle of the second day, when they were allowed to sit up.

The improvement in J. W. was most rapid and permanent; commencing disease in his right eye was at once arrested, and sight restored. In J. C. the mischief had been of longer duration; and the improvement, with the exception of cessation of all pain, not so well marked; the right eye continued weak and very tense. Yet in this case further mischief was arrested, and the man has since been able to work as a farm-labourer.

In addition to these cases, I may add one in which I have recently had an opportunity of observing in an advanced stage the effect of the destructive changes which arise in one eye after loss of the other by accident.

CASE V. Jane W., aged 21, when six years of age, lost the sight of the right eye by a blow from a bill-hook. Two or three years after this, the sight of the left began to fail, and she was then sent to an Asylum for the Blind, no attempt being made to save the left eye. She came to the Bath Eye Infirmary in May 1864. There were the remains of an eye collapsed on the right side. On the left, the central portion of the cornea was clear, but it looked altered in structure round the margin; the iris was changed in appearance, the pupil immovable, with the remains of a degenerated lens, so that she was quite blind.

On the 26th, I drilled through the lens, which was very soft and flocculent. She afterwards said she could perceive shadows and the difference between some bright colours.

In September, she returned to the infirmary, and was desirous that I should make a farther attempt to restore some sight. The eye was not altered in appearance since May.

On September 16th, I determined on enlarging the pupil by removing a portion of iris, but in consequence of the firm adhesions which existed between this membrane and the lens, this proved a difficult operation.

She was discharged on October 3rd. She had then a large pupil, which was entirely filled with opaque lens. She said that she could see better.

In these cases the progress of disease may be traced: commencing first in the deeper structures (the vitreous and choroid), and advancing, as in Jane W., to the lens and iris, ending in total destruction of sight.

From these and other recorded cases it would appear that secondary or sympathetic inflammation may arise in a few days or weeks, or one eye may remain quiet for many years after the other has been destroyed by accident. When once sympathetic inflammation has commenced, palliative treatment seems worse than useless; for much valuable time may be lost whilst changes leading to total destruction of sight are progressing, which changes are at once arrested by the removal of the useless and generally shrunk or atrophied eye.

Mr. White Cooper, in his work *On Wounds and Injuries of the Eye*, says: "It will be gathered from what has been said, that sympathetic ophthalmia is but little amenable to treatment; it may be palliated and slumber for a time, but with rare exceptions, it ultimately runs its course. The treatment which is applied with confidence to ordinary inflammations here falls powerless."

In the third volume of the *Ophthalmic Hospital Reports*, there is a paper by Mr. Poland, entitled *Medico-Legal Observations in Connection with Lesions of the Eye*, in which he says: "Where one eye has been injured, it is well known that it is liable to secondary inflammation, and may set up a sympathetic affec-

tion of the sound eye; so that this circumstance must be fully taken into account. Here also our hospital returns afford us no evidence. Mr. Cooper has attempted something of the sort, and records sixty-two cases which he has collected; but these are selected cases, and not so many sympathetic inflammations in so many injuries. What we want to know is the relative proportion of secondary inflammation and sympathetic inflammation in the sound eye, after wounds and injuries of the other eye. As far as our experience goes, it is not so great as is generally imagined; but this must be determined by facts."

Reviews and Notices.

CLINICAL LECTURES ON THE PRINCIPLES AND PRACTICE OF MEDICINE. By JOHN HUGHES BENNETT, M.D., F.R.S.E., Professor of the Institutes of Medicine, and Senior Professor of Clinical Medicine in the University of Edinburgh; etc. Fourth Edition. With Five Hundred and Thirty-seven Illustrations on Wood. Pp. 1021. Edinburgh: 1865.

THE third edition of this well known work having been for some time out of print, Professor HUGHES BENNETT has prepared a fourth; and, in doing so, he has subjected the book to a thorough revision, adding to it new matter to the amount of three hundred pages, but without materially increasing its bulk. Our readers—at least, many of them—are probably aware that the ten sections into which Dr. Bennett's lectures are arranged have as titles: 1. Examination of the Patient; 2. Principles of Medicine; 3. General Therapeutics; while the Sections 4—10 (both included) contain respectively the author's remarks on Diseases of the Nervous, Circulatory, Respiratory, Genito-Urinary, and Integumentary Systems, and of the Blood.

In the first section, there is no material alteration.

In the second section, the author has introduced an account of the molecular and cell theories of organisation. He refers to the theory of Schleiden and Schwann as to the formation of animal and vegetable cells, and their importance as the main agents of growth: to that of Goodsir, who held the nuclei rather than the cells to be the centres of nutrition or of germination; and to that of Huxley, according to whom, "a homogeneous plasma first exists, in which spaces (*vacuoles*) are formed, and these contain the cell-wall, contents, and nucleus. The walls of these spaces are called *periplast*, the nucleus *endoplast*"—the latter being unimportant as a nutritive element in comparison with the former. All these theories Dr. Bennett allows to be supported by numerous facts; but at the same time he holds that neither embraces all the facts of organisation; and in lieu of them he has proposed a theory—the "molecular theory"—in which the development and growth of organic tissues is referred to the minute molecules, of which each one is a centre acting by virtue of its physical and vital properties.

"This theory," says Dr. Bennett, "appears to me to comprehend all known facts; to unite the views of Schwann, Goodsir, and Huxley; and to explain the otherwise irreconcilable ideas concerning development sometimes proceeding from the nucleus, at

others from the cell, and at others from the intermediate substance." (P. 118).

The bearings of this theory on physiology and pathology are worked out in the succeeding pages. It is scarcely necessary, however, to dwell longer on the subject, as the views of Dr. Bennett on the action of molecules on growth and nutrition have already been put forth for controversial purposes both by him and by Dr. Beale, in this JOURNAL (vol. I for 1863.)

In the same section, the description of the general laws of nutrition and innervation in health and disease, of inflammation, and of tuberculosis, have been re-written. In speaking of morbid growths, Dr. Bennett holds strongly to the possibility of removing cancer, the microscopic characters of which have been determined beyond doubt, so that the patient shall not have a relapse; and in this he is supported by a letter received in October last from M. Velpeau, who tells him of several patients operated on by him at periods varying from six to twenty-eight years, and in whom there has been no return of the disease. In all these cases, M. Velpeau writes:

"Every precaution, whether clinical or anatomical, was employed, and the diagnosis established by direct observation, careful dissection, and microscopical research."

This view of the curability of cancer by operation has been long held by Dr. Bennett; and, as he observes, it involves an entire change in the meaning commonly attached to the term "malignant".

"Cases are now on record which prove that every kind of morbid growth is malignant, even in the worse sense of those who use that term; and that other growths, which the most experienced surgeons as well as histologists have declared to present the typical characters of malignancy, have been repeatedly excised with the greatest success. The establishment of these facts by the many recorded cases which may now be confidently depended on as having been carefully observed, and especially those of M. Velpeau, prove the impropriety of making this distinction between morbid growths." (P. 237.)

In the third section, Dr. Bennett has introduced remarks under distinct heads on the natural progress of disease; on the knowledge derived from an improved diagnosis and pathology; on the fallacy of the change-of-type theory; on our present means of treatment; and on the proposition that physiology and pathology constitute the true foundations for medical practice. Dr. Bennett insists on the importance of observing the natural progress of disease; viz., how long a disease naturally takes to get well of itself under favourable circumstances; what is its progress under unfavourable circumstances; and how far remedies are capable of shortening its duration.

"If every young practitioner", he says, "would dedicate his life to the careful elucidation of the natural progress of only one disease, he would do more for medical practice than has been accomplished by centuries of empirical trials of remedies." (P. 297.)

Of the change-of-type theory he utterly denies the correctness. Neither the human constitution, nor the human pulse, nor organic diseases, have changed their character. Recoveries from pulmonary tubercular disease occur much more frequently than was formerly the case; but, Dr. Bennett asks, "Are we therefore to believe that those affected with

phthisis and scrofula are stronger than they used to be?" Again, with regard to the pulse, Dr. Bennett points out that the experiments of Hales in 1732 on the force of the impulse of the blood produced the same results as those of Poisseuille in 1828 and of Vierordt in 1855.

"It appears to me, therefore, that the theory of change of type, so far from being established on well known facts, is, on the contrary, altogether fallacious, and entirely opposed to all the accurate data which histology, physiology, and pathology, have accumulated in modern times." (P. 302.)

All the remarks which Dr. Bennett makes in this section, as well as elsewhere, are deserving of the most attentive study. What he would have us to understand is expressed in the following words.

"An empirical treatment derived from blind authority, and an expectant treatment originating in an equally blind faith in nature, are both wrong.

"A knowledge of physiology and pathology is the real foundation and necessary introduction to a correct study of therapeutics.

"A true experience can only have for its proper aim the determination of how far the laws evolved during the advance of these sciences (physiology and pathology) can be made available for the cure of disease." (P. 351.)

In the more practical sections which follow, also, sundry additions have been made. In the section on Diseases of the Respiratory System, the author has introduced a carefully prepared table of all the cases of acute pneumonia—129 in number—which have been under his care in the Edinburgh Royal Infirmary from October 1, 1848, to January 1, 1865; following up this table by a summary of the results observed. He concludes, from the fact that 105 uncomplicated cases all recovered, that pneumonia treated by the restorative plan is not a fatal disease; also, that, in general, weakening complications or remedies prolong both the period of disease and of convalescence; that the amount of lung affected, or the presence of pneumonia at the apex of a lung, does not influence the result of the disease nor its duration—at least, to the extent generally supposed. The treatment he recommends is the following.

"For palliating symptoms, and especially pain and dyspnoea, warm fomentations and poultices I believe to be the best and safest remedies. Chloroform has been given by Varentrapp and others with good effect. No doubt, also, small bleedings, to the extent of eight or twelve ounces, give relief; but in debilitated persons they are dangerous, and in all tend, by weakening the strength at a period when the depressed system is struggling to retain its equilibrium, to prolong the convalescence and favour dangerous sequelae. Still, a small bleeding may be employed as a palliative with caution, to relieve engorgement of the lungs and congestion of the right side of the heart, although it is very rarely required. It should be remembered, in cases of double pneumonia, that there is often great dyspnoea on the sixth or seventh day, which will generally yield to warm poultices locally, and moderate doses of wine.

"As a curative treatment I am satisfied that the best plan is rest in bed, nutritive drinks, especially good beef-tea, from the first, arrested by four to eight ounces of port wine if the pulse become weak, and solid nutrients as soon as they can be taken. The elimination of the exudation may be further assisted by salines (acetate of ammonia, and small doses of tartar emetic, one-sixteenth of a grain) and diuretics

(nitric ether); although nature will accomplish this herself if the strength of the body be maintained. All active purgatives, contra-stimulants, depressants, anodynes, and lowering remedies of every description, should be avoided." (Pp. 712-13.)

In other sections, also, Dr. Bennett gives the results of his extended observation. In the tenth section, that on Diseases of the Blood, are some interesting observations on the administration of sugar in diabetes. Dr. Bennett observes that it is a question whether the cutting off of the external supply of sugar really affects the progress of the disease; inasmuch as the excessive formation within the body may continue in excess and exhaust the patient.

"Hence the idea that sugar furnished to the patient, instead of being injurious, might, by supplying him with the material the loss of which is so deleterious, serve to support his strength."

Piorry appears to have been the first to observe the actual diminution of diabetes in a patient under a saccharine diet; and the treatment has also been tried by Drs. Budd, Corfe, Bence Jones, and others, with generally favourable results. Dr. Bennett has carefully observed the effects of sugar in seven cases of diabetes under his care: and the conclusions at which he has arrived are:

1. We are still ignorant of how to cure diabetes.
2. The advantage to be derived from a purely animal or non-saccharine diet is over-estimated.
3. The giving sugar or employing a mixed diet produces no injury.
4. A non-saccharine diet diminishes the symptoms, controlling the hunger and thirst and diminishing the amount of urine and sugar passed, but does not cure the disease.
5. On this account it should be employed as a palliative when it can be followed without injury to the health, and especially where frequent calls to micturition disturb sleep at night." (P. 918.)

This book, as its title denotes, is eminently practical; the main object throughout being to illustrate the conclusions at which Dr. Bennett has arrived from a long and careful observation of disease. But, besides this, it is philosophical. The author endeavours to carry out the reconciliation of physiological and pathological observation with the practice of medicine; and hence we find, in the earlier sections especially, as well as in various parts of the work, the materials of a complete system of pathology and pathological histology, and also, though less elaborately put forth, of therapeutics. Many who read the book as all books of the kind should be read, with enlightened criticism, will doubtless find reason for differing from many of the opinions expressed by Dr. Bennett; but this must be the case so long as the theories of our science have not the absolute certainty of mathematical axioms. Whatever may be the result in this direction on the mind of the reader, he cannot study the book without deriving instruction from it, or without feeling grateful to the author for having so long and so usefully dedicated his talent and industry to the advancement of medical science.

A PRACTICAL ENUMERATION OF VARIOUS DISEASES OF THE HUMAN BODY OF BOTH SEXES.
By W. S. OKE, M.D. Second Edition. Pp. 100.
London: 1865.

It is not long since we noticed the appearance of the first edition of this work. A second edition has lately appeared—an evident proof that the book has found favour with the profession.

THE SURGEON'S VADE-MECUM; a Manual of Modern Surgery. By ROBERT DRUITT. Ninth Edition, much improved, and illustrated by Three Hundred and Sixty highly finished Wood-engravings. Pp. 860. London: 1865.

OUR old and valued friend the *Surgeon's Vade-Mecum*, whose name has long since become a "household word" among students and practitioners, now appears for the ninth time, with all the signs of having received from its author a thorough supply of the most sound and healthy material which modern surgical science can furnish.

To adapt and condense from time to time, for the benefit of the profession, the best established and the most newly approved doctrines of medical science and practice in any of its departments, is no small task for any one to undertake; but Dr. DRUITT has proved himself capable of performing it, and of keeping pace with the changes which time and thought and experience have produced in men's minds and actions in matters chirurgical. This constant attention which he has bestowed during more than twenty years on the progress of surgical science has culminated in a train of thought of which he gives an exposition in a highly interesting preface, wherein he comments on some of "the changes which have come over our profession in its ideas, theories, phrases, and rules of practice, during the five and twenty years which have passed since the first edition of this book." He remarks, for instance, how, in 1840, the doctrines of Cullen and John Hunter still held sway in pathology, and how

"The doctrines dominant among the great body of practitioners who had taken their tone from the teaching of an earlier generation, were *dynamic*; that is, they related to actions, forces, dispositions, and sympathies, supposed to exist in the animal body, with very little heed to *quantities* or to *composition*."

To deny, at that time, that all secretion and growth, and all organic change, were to be attributed to any other cause than the action of the blood-vessels, or that the absorbents were always on the watch to devour useless and superfluous material, was nothing short of heresy. When, Dr. Drutt says, he ventured in his first edition to say that pus might not only be formed by a process of secretion within the blood-vessels, but also outside them, he was obliged to speak cautiously—apologetically.

"An eminent teacher of surgery, with whom I was then familiar, reproached me almost as if it were a personal offence to suppose that any 'actions' could be done except by the capillaries, just as he considered me also a blind heretic for doubting the doctrine of John Hunter, that ulcers were eaten out by the 'mouths of the absorbents.'"

These errors of the past Dr. Drutt regards, justly, only as illustrations of certain vices inherent in the human mind—imperfect observation; wrong argumentation, in which that which requires to be proved is taken for granted; abuse of the "subjective", in supposing the figures of our imagination to exist in reality; assumption of final causes, whereby a moral purpose or intention was attributed to matter; and *rationalisticism*—the error of neglecting common-sense humble observation, and of trusting to *a priori* argument, in matters to which that line of argument is quite inapplicable." This rationalisticism—which

is as different from true rational argument "as a ghost from flesh and blood"—is, Dr. Druitt says, specially illustrated by the history of the abuse of blood-letting, which, as he reads its history, prevailed not with the ancients, but in the time from about 1790 to 1840, when practitioners persuaded themselves that they acted according to the scientific principles of John Hunter.

On the historical question we must differ to some extent from Dr. Druitt. No doubt, as he says, abuse of blood-letting did not prevail with the great English physicians of the eighteenth century; but, anterior to that time, there is evidence enough that the practice was carried to a very mischievous extent—perhaps more on the continent than in England. Any one who has read Molière's works, must have observed how pointedly he alludes, in his sarcastic manner, to excessive blood-letting as one of the abuses of the profession in his age. For instance, in one of his comedies, a physician in the course of a long harangue says:

"Premièrement, pour remédier à cette pléthore obturante, et à cette cacochimie luxuriante par tout le corps, je suis d'avis qu'il soit phlébotomisé libéralement; c'est à dire, que les saignées soient fréquentes et plantureuses: en premier lieu de la basilique, puis de la cephalique, et même si le mal est opiniâtre, de lui ouvrir la veine du front, et que l'ouverture soit large, afin que le gros sang puisse sortir, et en même temps de le purger, desopiler, et évacuer par purgatifs propres convenables; c'est à dire, par cholagogues, melanagogues, etc." (Molière, *M. de Pourceaugnac*.)

Returning to Dr. Druitt, we find him thus commenting on the causes of the abuse of blood-letting which prevailed at the time to which he specially refers:

"The hypothesis being that inflammation was an 'action' of the vessels (for they that believed in 'debility' of the inflamed capillaries believed in 'action' of the larger vessels), and the further hypothesis being accepted, that the action of the vessels was kept up by distension from within, it stood to reason that the way to diminish action was to empty the blood-vessels. Alas! that so many things which stand to reason (such as it is) should not stand to fact. But, as it was a logical deduction from established 'principles' that bleeding must diminish action, so practitioners went on bleeding in inflammation, consoling themselves for the deaths of their patients by the reflection that they had done their duty. That blood-letting in certain cases of the early stage of inflammation is of enormous service is an ancient and indisputable fact. There are many theories on which its good effects can be explained, among which may be mentioned that of Dr. Markham, that it is beneficial chiefly in inflammations which affect the act of respiration, and acts by diminishing the quantity of blood that need circulate in the lungs. But there is a fact I mention in these pages, which has been little noticed, and which may account for the perseverance with which blood was drawn in maladies where blood should rather have been injected—that is, the delicious sense of languor and ease which follows the abstraction of blood, as it does the Turkish bath..... Bleeding was done to excess, because our fathers had let themselves be led captive by the plausible 'scientific principles' of Cullen and Hunter; and bleeding is not carried to excess now, because homely observation has shown those principles to be but partially true."

In thus pointing out and unsparingly criticising

the errors of our forefathers, Dr. Druitt would guard himself from being supposed to condemn them absolutely, and to assert that we of the present age are altogether right. The main difference between the theories of the past and the present age is, that the latter are founded on a wider observation of phenomena than were the former; but it does not follow that the older theories were utterly wrong, or that ours are altogether right. On this point, Dr. Druitt expresses a rationally conservative opinion.

"The great thing to be desired is, that each generation should reverentially consider and adopt such of its predecessor's labours as stand the test of experience, instead of sweeping them contemptuously away and endeavouring to substitute an opposite and antagonistic universal theory. We need not be mere cellular pathologists, any more than mere vasomotor pathologists or humorists. Each of these doctrines has some foundation; but to apply any one of them universally, would be to bring back the darkest ages of physics."

This manner of treating the question is beyond doubt the sound one. We can no more reject the whole of the medical doctrines of our ancestors because they contained very much error, than astronomers can reject the entire teachings of the fathers of their science because these teachings were mixed up with imperfect observations and erroneous theories, and overlaid by the absurdities of astrology.

Dr. Druitt alludes to several instances of the changes in medical science. First among these is the revival of the ancient humoral pathology, which prevailed from 1842 to 1862, and has since been modified by the recognition of the action of the tissues as well as of the blood in the genesis of disease. Our knowledge of tumours, again, has undergone a thorough change since the introduction of the microscope into general use. On this subject, Dr. Druitt has bestowed special study, and more than ten years ago expounded his views in a paper read before the Medical Society of London and published in the ASSOCIATION MEDICAL JOURNAL. He now recognises the necessity of a classification founded on the anatomical elements of tumours, but believes that

"The cancers form but one part of a series, of which common inflammatory exudation or cell-growth, chronic inflammation, thickening and induration (the ancient *scirrhus*), cachectic or cacoplastic inflammation, as erysipelas and carbuncle, serofulous exudation, the fibro-cellular, fibro-plastic, fibro-nucleated, and fibroid tumours, together with the 'exudations' of rheumatism, gout, syphilis, and elephantiasis, are all closely related members..... A real advance will be made when the childish words 'malignant' and 'recurrent' shall be banished, and when all tumours of the kinds I have just enumerated shall be acknowledged to be individual members of one group."

It would be a long task to follow Dr. Druitt through all the instances of improvement in surgical science and practice which he enunciates, and which are illustrated in the body of his work. It must be sufficient for us to say, that he has brought his book well up to the present state of pathological and surgical knowledge; and that in this he has not acted as a mere compiler, but as a man capable of appreciating the relative value of the doctrines placed before him, and, in many instances, of expressing an opinion of his own. He does not, however, always trust to his own judgment; but says that, as for

many years his practice has been confined to surgery and midwifery, he has had the book, "especially all parts that relate to pure or operative surgery, submitted to the revision of an accomplished hospital surgeon."

To recommend this book to the profession would be superfluous; but this we must say, that Dr. Druitt deserves hearty thanks for having given the profession such a thorough epitome of modern surgery. We believe that there is not a single modern improvement in doctrine or practice, which is not here put forward with that conciseness of language and completeness of important detail which have been long known as leading characteristics of Druitt's *Surgeon's Vade-Mecum*.

A MANUAL OF THE PRACTICE OF SURGERY. By WILLIAM FAIRLIE CLARKE, M.A., F.R.C.S., Surgeon to the St. George's and St. James's Dispensary, etc. Pp. 352. London: 1865.

THIS book is written with a very good intention. The performance is also generally fair, as far as the actual contents are concerned; but we think the author has attempted an impossible task in seeking to compress the present science and practice of surgery within so small a volume, each page of which has a superficial area of little more than one-fourth of a page of this JOURNAL. We agree thoroughly with the remark of an author, whose long experience in epitomising surgical science gives his opinion special value.

"Surgery," says Dr. Druitt, "can now be condensed within no small space, and at best this work" (the *Vade Mecum*) "can but pretend to be a series of memoranda, sufficient perhaps for most maladies which fall to the lot of the practitioner, but not for those intricate subjects which claim special treatises to themselves."

MR. CLARKE'S *Manual* contains no illustrations, which are of the highest importance in works of surgery; and he omits, as far as we can observe, any allusion to the ophthalmoscope or to acupressure. Ovarian disease and ovariectomy, too, are dismissed in little more than one brief page; the directions for the operation occupying but fifteen lines. We can scarcely recommend this work in its present state to the profession; it may, however, sometimes be useful as a remembrancer.

SMALL-POX: HOW TO ANNIHILATE IT; OR, Observations on the Pernicious Consequences of Imperfect Vaccination, and on the Necessity of re-Vaccination. By R. T. LODGE, M.D. Liverpool: 1856.

DR. LODGE, the public vaccinator for Everton, has published a pamphlet, under the above title, to show the necessity of re-vaccination. He brings together an overwhelming mass of evidence in favour of re-vaccination. He fully believes that, by a properly carried out system of vaccination and re-vaccination, small-pox may be annihilated. He describes minutely the details of a good and of a bad vaccination. He especially dwells on the necessity for many—from four to even twelve—punctures. At fourteen years of age, all children should, in his opinion, be re-vaccinated.

British Medical Journal.

SATURDAY, MAY 27TH, 1865.

A PROPOSAL FROM STROUD.

MR. R. B. CARTER has addressed *A Letter to the Members of the British Medical Association on the Subject of their future Journal*; and as he promises, at our next annual meeting, to give the Association an opportunity of expressing their opinions on his proposals, our readers may, perhaps, be curious to know what his proposals are.

The medical profession, he argues, labours under many grievances; and all because the public are not properly made aware of their existence and nature. If, for example, the eloquence of an *Edinburgh Review* had been at hand to enforce on the public the facts and arguments used by Mr. Griffin in behalf of union surgeons, "how different would be the present state of things!" Again, abuses meet us at every turn. "Boards of guardians," Mr. Carter says, "cheat and rob their medical officers, as part of the system on which they cheat and rob the poor." Again, we have "some of our examining boards engaged in an unworthy and degrading struggle for fees, and refusing to require from their candidates such a preliminary and professional education as the present state of medical science renders necessary." Also, "we see teachers of medicine abusing their position as members of the Medical Council, and preventing the adoption of a higher standard of examination, avowedly lest it should for a time diminish the number of pupils at their respective schools, and thus diminish their receipts."

Now, if we only had the means of "teaching patients what is the precise value of a cheap doctor, and what is the nature of the process by which the article is manufactured for the market," we should then have, argues Mr. R. B. Carter, a perfect cure for these and all the other evils which afflict us. True, our medical journals talk continually about these evils; but then they only talk to the profession; they tell the public nothing about them; and what we want above everything is a journal that shall enlighten and influence the public. Such a journal Mr. Carter here offers to the Association and the profession. Its nominal qualities are as follows. It must be of such excellence as to support itself by its own inherent goodness; it must require no subsidising. It must be published quarterly, by a publisher of repute. It must be addressed to the educated public, rather than to the profession. The title must be brief, but *not* medical. The editor must never write in it: all contributions must be anonymous, and paid for at "the highest current rate".

Now, such a journal Mr. Carter promises to put into the hands of the members of the Association for £1,445—"a total which would scarcely exceed one-half of the subscriptions of the members." The advantages are these. "We should obtain considerable power of purse"—i. e., he says, "£1,000 or £1,200 a year," which, of course the Association might dispose of in a variety of benevolent ways, as he says, legal, parliamentary, or scientific; £500 might go to oppressed brethren, and £500 to the Provident Fund. But so many suggestive claims arise for the £1,000 or £1,200, that Mr. Carter becomes wisely cautious, and adds: "I think it would be rash to dispose of our surplus too hastily; and am content to point out that it would form a lever that might be used in various ways." Besides, as he hints, £100 a year will be required for advertising the new journal "outside the profession"; and, again, in some cases, £10:10 a sheet must be paid for contributions, which will probably take another £100 from the aforesaid surplus of £1,000 or £1,200. Moreover, our new Review, "like any other new undertaking, would require to be liberally fostered at the outset;" but, after two years, it would float of itself; and then, says the projector, the members shall have the option of paying their guinea and having the journal, or paying half a guinea and having no journal.

But then the Association must not "be left without some record of its public acts;" and this want is to be filled by quarterly or occasional "Proceedings", after the fashion of the *Proceedings of the Royal Medical and Chirurgical Society*—which "Proceedings", we may observe, by the way, the Council of the Royal Medical and Chirurgical Society have been recently discussing the propriety of abandoning.

The scheme, therefore, of Mr. Robert Brudenell Carter, as drawn by himself, seems to stand financially somewhat as follows.

	£	s.	d.
Paper, printing, etc. (rough estimate)	720	0	0
Contributions, at £8:8 per sheet	400	0	0
Editor's salary	200	0	0
Delivery by post	125	0	0
Advertising	100	0	0
Extra pay for contributions	100	0	0

To this must be added the expenses of publishing the "Proceedings"—an item which Mr. Carter has forgotten to note, but which we will put at £200. Neither has Mr. Carter considered it necessary to set down anything for the secretarial department of the Association, but which must, nevertheless, cost at least £250 *per annum*; thus making a total of £2,095. Now, we need hardly tell our readers that the patrons, especially the enthusiastic ones, of new schemes, rarely keep their expenses within their estimates; and we might, therefore, have fairly added another £200 for unforeseen expenses. We will, however, keep the publishing scheme as propounded by Mr. Carter himself; and we find that it, together

with the necessary business-expenses of the Association—small matters beneath the consideration of Mr. Carter—may fairly be expected to cost upwards of £2,000 *per annum*!

Now, when we turn to our Financial Reports of the four years preceding the last, we find that the average receipts from members of the Association amounted to (in round numbers) £2,080 *per annum*. Let us, however, take last year (1864) alone; in which, with between 2400 and 2500 members, the subscriptions received (including arrears) amounted to £2,500. Even in this case—the most favourable for his argument—Mr. R. B. Carter would be indeed a conjurer of the first water, surpassing Herr Frikel or even the Davenport Brothers, if he could spend very nearly £2,100 a year out of an income of £2,500, and then, at the end of the term, still find £1,000 or £1,200 at the bottom of the bag!

Such are the plan and promises of Mr. Carter, in accordance with which, he says, "it is proposed to submit a motion, embodying the project sketched in this letter, subject to such modifications," etc., at the next Association meeting; and he quite naïvely and innocently adds, to encourage his audience:

"Let me remind you that, if the proposed alteration be carried out, and be found detrimental to the interests of the Association, it will at any time be easy to return to the present state of things."

Mr. Carter, some persons will think, has forgotten the tale of killing the goose to get at the golden eggs; and has also forgotten that proverb which warns us against counting our chickens before they are hatched. Great schemers naturally do not concern themselves about minor details; but still some of our readers would have liked to hear how Mr. Carter has satisfied himself, that he will lose none of his audience—none of the present income of the Association—when the drop scene falls on the last act of the JOURNAL. Of course, the JOURNAL may have had nothing to do with the fact of the late increase of members; but still it is a fact, that when the JOURNAL came into the present editor's hands, the number of members was only about 1800. Under its present management, however, the annual average of withdrawals has not only been diminished, but several hundred new members have been added to the Association. Has the conduct of the JOURNAL, then, had nothing to do with the present prosperity of the Association? is a question which, at all events, evidently required a little examination at Mr. Carter's hands. Mr. Carter should surely, in the face of such facts as these, have devoted, in his twelve pages of pamphlet, twelve lines to show his reasons for assuming (as he does) that the income of the Association will be as great without as it now is with its JOURNAL.

On this head, we may fairly remind Mr. Carter of the opinion of an authority which he will no doubt

respect, of the Committee of Council. The Council, in their Report, spoke as follows in August 1861.

"There is every reason to expect that, if the JOURNAL be carried on with the energy and talent by which it has thus far been distinguished (under its present editorship), the number of associates will ere long be considerably augmented, and the Society at large hold even a higher status than it has previously attained."

Now, the Association since that date has increased greatly in numbers, and, we will venture to say, has attained a far higher status than it then held.

Surely Mr. Carter should, in the face of such facts as these, have given some reasons for his unargued assumption, that members are not kept in the Association by the JOURNAL.

Instead of this, he favours us with an estimate of the worth of the JOURNAL. He admits, that it has been of "great and unquestionable utility." But its work is done; and the Association should commence "a new career of active vitality"! The original contributions in the JOURNAL, Mr. Carter says, "on scientific subjects, are usually highly interesting.....and sometimes of extraordinary merit". But, then, the majority of them "do not at all enter upon the previously unknown"—a region which apparently has great attractions for Mr. Carter; and, besides, these contributions could always find space in other journals; and, in Mr. Carter's opinion, the business of the Association is more to foster social than scientific progress. As to the correspondence of the JOURNAL, it is of "languid interest". Its intelligence is behind hand; and as for its editorial compositions, they are beneath contempt.

"The editorial compositions would not, I venture to think, be missed by any living creature. They are chiefly remarkable for having attained that degree of extreme badness at which no amount of ingenuity could find any means of making them worse."

Rare specimens, indeed, must they exhibit of the "art of sinking." Surely some credit is due to the "ingenuity" of an editor who is able to reach down to such a depth of "badness." There must be a novelty and originality, a specialty, in his work in this way.

The only thing further required is that, at the Leamington meeting, the Associates should decide the question, "whether the Association be strong enough to lay aside leading-strings and enter upon action"—i. e., to start a "first-class quarterly review"; whether, in fact, they should put down their present one-horse (broken-winded and spavined) "shay", start a spick-and-span new four-in-hand, mount Mr. Carter on the box, give him the ribbons and the lash, and commit themselves under his skilful Jehuship to the glorious rush of four fiery real thoroughbred quarterly Pegasi.

Mr. Carter has not the slightest doubt that an experiment would determine this question in the

affirmative; and, no doubt, Phaeton-like, he is quite ready to undertake the experiment, if the Association will only say, *Fiat experimentum*.

Such is the scheme, long promised, carefully prepared, and elaborately hatched, by Mr. Carter. By means of his quarterly review, he will regenerate, *in primis*, the British Medical Association, and *secundo*, through it, the social life of British medicine.

THE COMING COLLEGE ELECTION.

WE are happy to be able to state authoritatively, that it is the full intention of Mr. Turner of Manchester to offer himself as a candidate for the Councilorship of the College of Surgeons. His success is, we should hope, certain. As a representative of surgery, and as a Fellow of the College, he is in every way highly qualified for the office; and we would remind our readers, that he has already pledged himself to perform fully the duties of Councillor if elected. We can hardly believe the country Fellows will allow such an occasion as this to pass without asserting their rights in Mr. Turner's, or rather we should say in their own, favour. Mr. Turner will enter the College in the liberal interest; and will assist in the removal of those close borough principles upon which the College is still administered, but which are, we trust, gradually yielding before the force of enlightened professional opinion. If we were again to tell the tale of the misdirection of the College under its present administration, we should have little more to do than repeat the words which for the last three or four years have been annually said in these pages.

We do not blame those who are the agents of the misdirection, because we believe the evils are inherent in the constitution of the College. And for such evils, there is but one remedy, and that is an alteration of the Charter; and, in the meantime, a pledge should be extracted from those who enter the Council that they will vote for such an alteration. We have already had elections of *soi-disant* reforming councillors; but what have they really hitherto done towards carrying out the principles of the Charter of the College? Have they ever fought the battle of the election of Examiners from outside of the Council? Never to this day has the Council elected an Examiner who was not one of themselves; nor elected a President or Vice-President who was not a member of the Court of Examiners: although indirectly told by the Charter of the College to do so. The country Fellows, again, are virtually excluded from voting at the election of Councillors, because they cannot vote by written papers: and why should it not ask for an alteration of its Charter in order to obtain for them such right of voting? Why should

the election of Councillors be really in the hands of the London Fellows?

The truth is, that the present institution of the College is at fault, is radically defective, and naturally conducive to the evils complained of. To produce an effectual reform, the Charter must be altered. The members of the Court of Examiners must cease to be members of Council; or, in other words, the Examiners must cease to elect and re-elect themselves. The whole proceeding is action in a vicious circle, and in this way. The Council is the door of entrance—the only door, as the Court will have it—to the Court of Examiners; and the examinership is the rich prize which the Councillor ever has before his eyes. But to become an Examiner, the Councillor must have favour in the eyes of the Court of Examiners, who rule supreme within the Council. But no Councillor of reforming tendencies has favour in the eyes of the Court. The Councillor, therefore, who lives in hopes of an examinership is discreet, and follows the retrograde tendencies of the Court of Examiners. So long, therefore, as the Examiners are members of Council—*i. e.*, we again repeat it, so long as they reign supreme in the Council, and virtually re-elect themselves—there seems little hope of any real reform being effected in the College.

But Mr. Turner has no intention of becoming an Examiner—as a rule, country members would not seek the examinership—and therefore is especially pointed out as a proper representative of the interests of the Fellows and of the College. It is only by men of his stamp that the first step of real reform—an alteration of the Charter—can be obtained, and so a separation of the present improper and unnatural connexion between the Council and the Court of Examiners effected. And can anything be more unnatural than that the Examiners should form part of the Council which elects them? Can it be right that the Examiners should virtually have the power, and should exercise it, too, year after year, of re-electing themselves to office—to the very lucrative and important office of Examiner? We blame not individuals; but then, unfortunately, individuals must in the meantime necessarily bear the odium of the bad government which they administer. And thus it is that the retiring Councillor who offers himself for re-election must bear the burthen and the penalty of the evil system. It is only through his rejection that the Fellows can speak out their opinions. The Fellows very properly regard him as responsible for the shortcomings of those whom he represents. He is responsible to the country Fellows that they have no power of voting by proxy, and for all the other evils of the present system as now administered. Besides this, it must not be forgotten that re-elections perpetuate one of the mischiefs which the last Charter was especially meant to remove; viz., the holding of office for life. Confidently,

therefore, do we trust, for the general good of the College, and for the especial benefit of the country Fellows, that Mr. Turner's election will, at all events, be secured. If the country Fellows on the present occasion fail to carry his election, we shall be forced to the conclusion that they really are apathetic as regards the power of exercising their rights as Fellows.

At another page will be found a note, which exemplifies in a remarkable manner the unfortunate condition of the Poor-law medical officer. A Committee of the House of Commons lately recommended that cod-liver oil and quinine, etc., should be paid for by the union, instead of being supplied by the medical officer. This recommendation was meant as a boon to the medical officer. But how has it been received? The Launceston Union write to their medical officer, and beg him to say what reduction in his salary he will submit to if the Board provide cod-liver oil as a medical extra!—the manifest intention being that the medical officer shall still pay for the cod-liver oil. We shall be anxious to learn how the Poor-law Board and the House of Commons' Committee accept such a shameful evasion of their manifest intentions.

DR. FAYNER, of the Bengal Army, on February 14th delivered the address at the annual meeting of the Bengal Branch of the British Medical Association. He chose for his subject "Surgery in Bengal". He referred to the immense field for experience which surgeons had in India, and expressed his surprise that surgery in India was so little heeded in "the West".

"I will venture to say that you will have difficulty in adducing even a casual reference, in any of the standard works of Britain professing to treat exhaustively of their respective subjects, to the authority, practice, or opinion of one Indian surgeon. Let us take the operation of lithotomy, for example. Not a word on the subject as it relates to India, where we count our operations by hundreds, I may say, and where some of our graduates have cut as many men successfully for stone as the greatest lithotomists Europe ever saw. I may refer to my friend Baboo Ram Narain's experience, who, within twelve years, in Cawnpore and Budaon, operated upwards of two hundred times, with a loss of seven cases. Or I might adduce a donation of seventeen large vesical calculi, presented to the College Museum by a graduate whose degree is not a year old, and removed by him. And I might refer to the names of O'Shaughnessy, Brett, Webb, Playfair, Naismith, Aitcheson, Partridge, Cayley, and others, as of surgeons who have had experience in this operation that scarcely the Frère Jaques, Rau, or Cheselden ever exceeded. And as in the case of lithotomy, so it is in other matters surgical; the scrotal tumours, for example, of which the hospitals in Lower Bengal record operations by the score. Tumours of vast magnitude removed with safety and celerity in a few minutes, the important parts involved being preserved and uninjured—a strange contrast to the descriptions still

to be read in standard works on surgery, of protracted and dangerous operations, involving not only loss of parts, but sometimes of life."

Dr. Fayrer then refers to some statistical details for the second half of 1863.

"In Bengal, there were sixty-eight cases of lithotomy with eight deaths, or one death in 8.5 cases; in the North-west and Punjab, five hundred and fifty-five cases with fifty-seven deaths, or one death in 9.9. In Bengal, forty-six cases of scrotal tumour with two deaths; in the North-west and Punjab, one case of ditto, and that recovered."

Dr. Fayrer, also points out grievous faults in the construction of some of the hospitals in India; and refers to gangrene, etc., and increased mortality, as the result. He also especially alludes to "one of the frequent causes of death after amputation or other injuries, or operations involving section of bone."

"In illustration of this, I have noted a series of amputations. In the Medical College Hospital, these amputations, thirty-two in number, were all capital operations. They were: one of the hip, three of the thigh, ten of the leg, four of the ankle (Syme's), five at the shoulder-joint, five of the arm, four of the forearm. Of these, thirty-two in all, three were secondary amputations; and of the number, fourteen lived, fifteen died. Of the deaths, nine resulted from pyæmia, the consequence of osteo-mycelitis; three from pyæmia not depending on bone-disease. There were six deaths from other causes, such as tetanus, gangrene, exhaustion. This proportion of deaths from pyæmia, depending on bone-disease, is something unusual—something very different to the ordinary death-returns of other hospitals."

Dr. Fayrer then enters fully into the history of osteo-mycelitis—a subject which was lately fully discussed at the Medical and Chirurgical Society, and in consequence of the attention of late called to it, especially by Dr. Fayrer. It is gratifying to find a man of Dr. Fayrer's experience recognising so fully as he does the benefits and utility of the Bengal Branch of our Association.

THE monster evil, gratuitous medical services, will, we suppose, in the long run, produce its own cure. We fear there is no appearance of cure coming from any other quarter. We perhaps ought, therefore, rather to rejoice at the increase of the evil, than to mourn over it. Village hospitals are springing up over the country—of course, all supplied with gratuitous medical services; and now are rising up a new style of hospitals, where patients are to be admitted who can pay 10s. or £1 per week. This is all well. But why should doctors work for them gratuitously? Why should they take away from their humbler brethren their paying patients, and treat them gratuitously? We see a prospectus flying about for a "new wing for paying patients" at the "Hospital for Women"; but nothing of any pay for the doctors who are to attend them. But why not? And why do doctors propose to give to "paying patients" their gratuitous medical services? Is it

out of a pure, heaven-born love of doing good? Is it out of pure charity? Is it ———? But perhaps some of our readers can give us a satisfactory reply. We have often asked, and long waited, but never yet received one.

M. BOUCHUT, of the Children's Hospital, Paris, has called in the ophthalmoscope as a diagnostic agent in chronic hydrocephalus and rachitic state of the cranial bones. In chronic hydrocephalus, the early signs of the disease, he says, are often obscure: but the vessels of the eye always undergo appreciable modifications. In proportion as the serum accumulates in and compresses the brain, we find—1, an increase of vascularity of the retina, with dilatation of the veins; 2, an increase of the number of vessels in the retina; 3, a complete or partial serous infiltration of the retina; 4, atrophy of the retina and its vessels; 5, atrophy, more or less marked, of the optic nerve. These lesions vary with the age of the disease and the amount of serous effusion. They result either from compression of the sinuses preventing the return of blood from the eye, or from compression of the optic nerve within the cranium. But none of these lesions exist in rickets. In twenty-two children between five months and three years of age, examined by M. Bouchut, in whom the body was only slightly deformed, but in whom the head was increased in size and the anterior fontanelle open, and some of whom had, and some of whom had not, had convulsions, the eye preserved its natural appearance. There was neither alteration of the pupil, nor any disorder of the venous circulation of the retina. Hence, he says, by means of the ophthalmoscope, we can distinguish between rickets and chronic hydrocephalus.

The *Gaz. Méd. de Lyon* tells of an English Life Assurance Society which takes the lives of persons treated homœopathically at a lower premium than those treated medically—statistics having shown that the former sort live the longest! Homœopathy, it adds, is sensibly losing ground in Lyons—"following the usual course of all errors".

The illustrious and venerable Professor Bufalini, says *L'Imparziale*, has commenced a course of clinical medicine. "Our great pathologist is still in the full vigour of mind and body." The same journal announces the death of the "illustrious reformer of Italian therapeutics, Dr. Semmola. He was a type of goodness and benevolence, independence and liberality. Loving his Italy with a tender love, he suffered for her in exile and in prison, under the tyranny of the Bourbons. Twice he was elected deputy."

L'Union Méd. tell us that, at Lübeck, the Senator Dittmers and all his family, consisting of seven persons, had been poisoned by eating a smoked uncooked ham, which was filled with trichinæ. Four persons had already died.

A RAMBLE IN THE ENVIRONS OF YOKOHAMA.

BY A MEDICAL OFFICER OF THE ROYAL NAVY.

IN the following notes, I will endeavour to convey to the reader some notion of the peculiar scenic beauties of the country in the neighbourhood of Yokohama,* as it appears during the pleasant month of May (Ya yoi ts'ki, or "development of nature" month, as the Japanese aptly term it), and some little insight into the everyday life of the simple peasantry of Dai Nippon.†

On a sunshiny, breezy afternoon, then, such as are frequent during this the pleasantest season of the year, I crossed one of the solidly constructed wooden bridges that arch over the narrow creek or canal that encompasses and isolates Yokohama, and passing the "kamo", or guard-house, where the squatted green-capped sentinels were whiling away their time of duty over tea and tobacco, I followed for some distance the course of the stream, in which idle Yakunins, girt with immense swords, were peacefully fishing, and ragged urchins (*more universo*) were delightedly dabbling in the mud, and speedily gained the open space at the head of the straggling village of Hon-moora, having met with, even in this short walk, evidence enough of the peculiar civilisation of Japan to furnish matter for yet another additional chapter to Mr. Buckle's laborious work. There were several sheds or booths, generally presided over by sharp-eyed old women, and exposing for sale various creature comforts for the delectation of the natives—small masses of rice, bits of queer-looking fish, slices of "tako" (cuttle-fish) for the luxurious, dumplings of indigestible dough skewered on strips of bamboo, and various other comestibles of an appearance more odd than enticing, flanked by minute cups of tea and small bowls of "sake". A nursery-garden, crowded with bright-hued flowers, with delicately leaved shrubs, with cypresses and curiously dwarfed trees in pots and tubs, formed a pleasant contrast to the mean and dingy mass of these humble *restaurants*.

Opposite the main street of the village, which lay baking in the sun, with its long, open, central drain festering with unsavoury odours, were the portal and flight of steps of a small temple; a prelude to a much larger one, if I could trust a huge board set up before me, which displayed a carefully executed drawing of a building of very imposing proportions, and which was intended, doubtless, as a hint to the faithful, that "contributions would be thankfully received."

Leaving the village on my right, a few steps brought me to the entrance of the foreign cemetery, which occupied the base, slope, and summit of a tree- and shrub-covered inconsiderable hill. Here the only striking object is a square stone structure, with four supporting pillars, and surmounted by a burnished copper dome. This was erected by the Japanese, at the instance of the Russian Government, to the memory of their sailors murdered in Yokohama in August 1859. The great majority of the graves are those of officers and men of the various ships-of-war that have been or are stationed in the bay; the summit being occupied by the French, the slope by the English, and the base by Russians, Americans, and Dutch. The graves appeared to be kept in tolerable order; but it was still evident that the poor

fellows whose last resting-places they were had died far from the loving remembrances of relations and friends.

Pursuing the path that skirted the base of the hill, I passed, a little further on, a small native cemetery,* remarkable only for a row of half-defaced stone images, with bags of pebbles hung round their necks and heaps of the same collected in front of them, as votive offerings, probably from the poorer classes; while, beyond this again, in a pleasant shady nook at the head of the valley, was another and much larger cemetery, through which short flights of steps brought me to a winding path among the trees that led to the summit of the broken range of low hills that forms the southern boundary of the wide alluvial valley in which Yokohama is situated. I paused here a few moments to inhale the fresh breeze that was blowing from the Gulf of Yedo, and to enjoy the extensive view that lay stretched out before me. For, as I looked down the valley, over the white-edged tiled roofs of the houses of the foreign quarter which lay glistening in the sun, over the blue waters of the bay, where rode quietly at their anchors the men-of-war that assured peace and prosperity to the community, over the straggling town of Kanagawa on the further side of the bay, with its frowning fort mounted with guns *en barbette* (as are almost all Japanese forts), over the low wooded hills beyond and the flat lands that stretched far out into the Gulf—my vision was arrested only by a blue line of distant hills, far away beyond the heights that overlook the capital city.

Here a somewhat uneven path led me, now along a comparatively broad and undulating table land, now along a kind of flat ridge, from which the cultivated or shrub-covered ground sloped away gently on either side. I passed through wheat-fields already commencing to change the green tint of youth for the brilliant gold of maturity, through patches of yellowed-flowered rapet redolent with a fragrant perfume, through masses of peas or beans in full flower; or I skirted shady groves of young pines in full blossom, and looking like huge Christmas-trees loaded with unlit tapers, or forced my way through thickets where palms, conifers, and bamboos, were intermingled with the red-flowered camelia, the brilliant *Azalea Indica*, the climbing, prickly *Smilax China*, and were hung with festoons of a curious purple-flowered fragrant twiner.

My route was protected by several of those guard-houses (or "kamo"), that have been erected ostensibly for the benefit of foreigners; but apparently only to harbour a set of idle and very dirty Yakunins, who dawdle away the day in tea-drinking, tobacco-smoking, and not seldom in sake-bibbing. There is nothing to distinguish these "kamos" from an ordinary house, except that they are somewhat larger, and are furnished with the array of hooked, curved, and barb-set spears, characteristic of an official resi-

* As in China, cemeteries are generally in some shady and retired nook. The gravestones are often simple slabs or columns, sometimes ornamented with an overhanging carved cornice. In the pedestal on which this slab or column rests, and in front of the latter, three holes are invariably scooped out, which contain sometimes water, sometimes little bowls of rice, sometimes joints of bamboos, in which joss-sticks are slowly burning. Some care appears to be taken of the graves for a certain time; but after that they seem to be altogether neglected. The coffin, which is nothing but a common square box, contains either the body bent on itself, so as to be held in the smallest possible space, or the ashes of the body after "kwasoo" or incineration has been performed, which appears to obtain chiefly among the better classes, and especially when a person dies far away from his own district. I am informed by the natives that, when a person is moribund, a powder is administered to him, which has the effect of obviating or delaying the *rigor mortis*, so that the adaptation of the body to the coffin, should "kwasoo" not be performed, may be more easily effected.

† *Brassica Chinensis*.

* Literally, Cross-shore.

† Or Great Japan. Nippon is compounded of two Sinico-Japanese words, meaning "the rising sun" or "the rising day".

dence. The men are sometimes retainers of the Tycoon, sometimes of Daimios subservient to him, and when they are changed, a copy of the "mon", or device, on their clothes is always forwarded to our commanders and consuls. Often the guard-houses are tenanted by the new levy of infantry, a dirty-looking set of rustics, wearing two swords and a green over-garment, whence the common people have given them the nickname of "nappa", or vegetable coats.

These men are drilled in the European mode. They manage the manual exercise very well; but their company drill is a miserable failure, and they seem quite incapable of steady marching in column. I do not think that the British soldier will have much to apprehend from these *quasi-militaires* for many years to come.*

At the last of the guard-houses, I began my descent into the valley, and skirted the base of a grassy bank, sparkling with the blue flowers of *Cynoglossum Japonicum*, with the brilliant carmine petals of a low rosaceous shrub, with purple violets, and rarely with a pretty yellow orchid, and a small arum. Leaving the path, I picked my way along the "nawade", or raised narrow turfy embankments which are the only divisions between the fields, and, gaining the bottom of the valley, crossed the paddy-fields, and reached the banks of the stream, which was pleasantly murmuring beneath the shrub-covered broken ground of the opposite side.

Of such valleys, and their intervening irregular ranges of hills, the whole country appears to consist. They are of all degrees of depth and width; but generally widen as the coast is approached. The bottom is generally converted into paddy-marshes or is left uncultivated, whilst the slopes are planted with cereals, etc., intermingled with patches of forest of tangled shrub, and groups of sakura (cherry-trees) or brya (mespilus) trees. Often no cultivated ground is visible; and the whole dale then has the appearance of a vast garden or shrubbery run wild in rich profusion, under nature's superintendence only.

The marks of the denudating process by which these valleys have been formed are evident everywhere; and if they were filled up to the level of the top of the enclosing hills, an almost flat surface of many miles extent would be formed. The underlying rock is a greyish sandstone, so far as I have been able to make out, non-fossiliferous, and easily disintegrating, under the combined influence of air and moisture, into a light friable soil, thicker, but not clayey, in the paddy-fields, and becoming on the slopes a dark-brown mould, rich with the often laid on and highly potent manure, and apparently very free from worms and grubs. As in China, human manure is chiefly used; and, as a result, the vegetables and fruits are abundant, but singularly deficient in flavour.

In sections near and along the shore, I have noticed alternating strata of shells, gravel, and sandy soil, the shells being apparently all of recent species and many only imperfectly fossilised: clear evidences of the various upheavals and depressions which might, *à priori*, have been expected to be met with in this volcanic country.

I ascended the valley in following the windings of the stream, whose banks were crowded with shrubs, among which the yellow-flowered prickly *Berberis cretica*, a species of wild *morus*, and the *fuji no ki*, a leguminous bush with handsome large racemes of lilac flowers, were prominent. And wherever the

stream wound beneath an overhanging broken bank of disintegrating dripping rock, this was sure to be crowded with the large coriaceous fronds of *Woodwardia japonica*, with various *Polysticha* and *Lathrææ*, with the well known *Osmunda regalis*, with a delicate *Davallia*, with the pretty *Grammitis decurrens*, with *Pleopeltis nida*, *Cystodium falcatum*, and many others, which it would be long to catalogue here.

I saw no four-footed animals—no hares, rabbits, nor foxes; but, nevertheless, the animal kingdom was well represented. Various spiders were lazily watching for prey; and one especially caught my attention, a huge bloated fellow, fully three-quarters of an inch long, with yellow spots and bands on his black fat body, and whose "laxi casses" hung on almost every bush. Dragon-flies were skimming over the surface of the water or poising upon the tip of a leaf or twig—dragon-flies of various hues; some with scarlet bodies and emerald green wings; some with bodies of lustrous steel and wings of burnished copper; and many other forerunners of the countless varieties that the approaching summer would show us.

Butterflies and moths there were in plenty; but not so numerous nor so gorgeous as they will be a month hence. The lithe, bright-eyed, brown lizard hurried through the grass, frightened by my approaching footsteps; and now and then a startled snake glided across the paddy-fields, with head erect and protruded tongue, both of us glad to be out of each other's way; whilst the rice-marshes were peopled by innumerable green frogs, that peeped for an instant above the mud as I passed by and quickly retreated again, as if dissatisfied with their inspection of me. Birds did not appear numerous; a pretty kingfisher, a prettier woodpecker, the ubiquitous crow, a kind of wagtail, flights of small birds not much larger than humming-birds, occasional wood-pigeons, and a rare pheasant startling me by its sudden and noisy rise at my feet, were all I noticed.

And as I ascended towards the head of the valley, leaving the rice-marshes behind me, the croaking of the frogs, and the hoarse cry of the ravens amid the pine groves, mingled with the sound of the frequent tap of the woodpecker as he industriously gained his afternoon meal, of the coo of the woodpigeon in the neighbouring copse, and of the twittering of the small birds, so as to blend in a not inharmonious murmur, suggestive of life and activity and enjoyment.

I saw no work doing on the slopes. The crops were half-ripe, and the peasants were waiting for the well-earned reward of their careful and persevering labours. But in the rice-fields was more activity. Men, women, and children, were busily employed in turning over the thick soil—no easy task; and then reducing it to an impalpable mud ready for the seed. I was glad to see that the heaviest work was done by the men, and that that of the women, though heavy enough, was comparatively light. Some few of the fields already showed the emerald green of the young shoots of rice just springing above the ground. When the young plants grow strong enough, they will be removed into the rougher, less elaborately prepared fields, and there will become ripe. The nurseries, as they may be called, are variously protected from the ravages of the crows and pigeons by radiating networks of cords, by bamboos provided with wooden rattles consisting of a loosely attached board against which hang a number of wooden pegs, or by more or less elaborate scarecrows, generally representing a Yakunin with beaded bow and arrow, on the point of departure.

Arrived at the head of the valley, a short walk brought me within view of Mississipi Bay; and a

* Their pay is, according to their own report, three riao a month (about 25s.), for which they find themselves in everything. There are, I believe, about 1500-2000 of them in and around Yokohama.

violet-covered bank, beneath the shade of a tall camelia tree,

"Ingens Fernstroemia inumbrat,"

invited me to rest awhile, and inhale the breeze that swept up the hill, bringing to me the sweet scent of the yellow rape-fields over which it had passed, and soothing me with the pleasant murmur of its rustling amid the neighbouring copse.

What a splendid scene on every side!

Before me lay undulating masses of green and yellow relieved by dark patches of wood or tangled thicket, and stretching away down to where the weathered cliffs of whitish sandstone barred the further progress of the ocean; on each side, the bold sweep of the bay, defended by a glistening line of pine-crowned precipices, bristling with endless wooded capes and headlands, the guardians of the entrances of endless creeks; while the blue expanse of water, dotted by a thousand white sails, was bounded by the distant blue hills of the province of Kadsusa, and added a charm to the landscape that may be felt but not described.

As the roar of the distant breaking surf ("*Magno misceri murmure pontum*") was borne to me by the breeze, my thoughts flew homewards, and I recalled the exquisite lines, half sad half hopeful, of a modern poet:

"Que dice ese sordo acento
Que de la mar se levanta?
Es un himno ó un lamento?
Es voz que llora ó que canta?"—*Ochoa*.

By the sea had I come so far from home, and by the sea alone could I return home.

Looking to the north-west, a more extensive and more striking view was to be obtained. And to enjoy it more thoroughly, I gained the edge of a thickly wooded slope at some short distance from my former post; at the base of which extended a broad valley at an angle with the valley which I had been traversing. The plain at the bottom was dotted with villages and patches of forest and cultivated clearings; and beyond it rose an irregular range of pine-fringed hills, whose slopes were covered with timber or shrub, excellent but difficult covers for pheasants, and dotted here and there by a single farm-house or by a small hamlet, surrounded by tiny patches of brilliant green and yellow. And beyond was an interminable succession of hill ranges, more or less wild or cultivated, losing more and more their distinctive tints and becoming gradually almost indistinguishable from the grey neutral hue of the extreme northern horizon, or abruptly backed up by a line of purple mountains, at some little interval from which rose high into the sky, in all its solitary grandeur, the glistening snow-covered conical mass of Fusi Yama, full forty miles distant.

A steep path that wound among the trees between overhanging dripping banks, luxuriant with broad-fronded ferns, brought me to a little wayside shrine, a kind of rude penthouse, sheltering a half-defaced stone image of some local deity, which guarded, as it were, the entrance of a small village that lay at the bottom of the hill. Here I was quickly surrounded by a crowd of urchins of both sexes, running about me with cries of "*Tempo sinjo*" ("Please give me a tempo"), or "*Tempo injo*", where the voice was the young treble of a child just emerged from babyhood. These young hopefuls were terribly dirty, but fat and rosy withal, and appeared well fed and happy enough. Skin-diseases, however, were prevalent, especially on the head, owing, doubtless, to the various tortures to which the skin of that part is subjected. The houses were of ordinary construction, clean enough as regards the raised and matted portion where the family dwelt, but surrounded by

various heaps of immundities, the accumulations of filth and refuse of months. I entered one of the best looking of the houses, and asked for a cup of tea. With this I was civilly supplied, the tea being brought in a small cup on a neat little lacquered tray. The whole family, father, mother, sons, and daughters, crowded round me, abandoning their several occupations, and overwhelming me with questions. Was I Ingirisy (English)? Was I married, and how many wives had I? Why had I come so far from home? Had we such flowers in my country? (as they turned over a portfolio which I carried about with me for the purpose of holding botanical specimens.) Did rice grow there? And numberless others of a similar tendency. They much admired the cloth of my coat, my watch, my knife, etc., and when, by means of a burning-glass, I set some tinder on fire, a simultaneous cry of "*Naruhodo*" betrayed the extremity of their wonder. They said that the advent of foreigners had caused the prices of provisions and clothing to rise; and that in the more distant districts foreigners were accordingly detested. But, on closer inquiry, it appeared that the elevation of price was very small, though perhaps enough to be of serious import to them. The good man of the house was a farmer possessing about seventy acres of land. I could not get from him—as, indeed, I have never been able to do from others—more information about his tenure and rent than that he held his land under the Kubosama (Tycoon), and that the rent was appraised according to the crop.

The persons of my hosts were far from clean; and their clothes had evidently gone through long and arduous service. They appeared to pay no attention whatever to personal adornment, except the "*musme*", or girls, and with them it was confined to the arrangement of their plentiful black hair. I cannot say that Japanese women are pretty. The older ones—and they are old at 26—are positively hideous, with their wizened yellow faces, shaved eyebrows, and black teeth. And the younger ones are rarely more than passable; their curious style of dress, loose where it should be close, and tightly drawn round the legs where it ought to be loose, causing their motions to be restrained and ungraceful. In the opinion of some, however, their hesitating and feeble gait is not altogether deficient in a kind of helpless attractiveness. Of course, I only talk here about the lower classes, who are much exposed to the withering influence of the elements. I can say nothing whatever about the wives, daughters, and concubines, of the Daimios, or higher retainers, or Yakumins; for I never, to my knowledge, saw a specimen of them. And I ought, in justice, to modify the statement above, and to confine myself to the averment, that I have never seen any really good-looking Japanese women.

These villages ("*mura*") are under the immediate rule of a head man (Nanoshi), and apparently of a kind of superior policeman or sort of rural judge (Seiji).

But the declining sun warned me to depart homewards; and gratifying my poor but courteous hosts with a few tempes, I left their dwelling, after a polite interchange of "*Sayoo nara*", and hastening over the paddy-fields, reached the banks of the canal, a branch of that which encompasses Yokohama.

Among the many pleasing traits in the Japanese character, none is more so, to my mind, than the extreme and very unaffected courtesy which even the lowest classes can, and almost invariably do, show to each other and to foreigners; a somewhat humiliating contrast to the gross incivility, I might say brutality, commonly exhibited in some parts of England, more especially as it would be experienced

by any unfortunate foreigner whose dress should differ from ours in a far less degree than ours differs from that of the Japanese.

As I trudged homewards, I met numerous Europeans enjoying their evening ride, somewhat careless, I thought of the foot-passengers on the narrow path, and with not a few drunken Yakunin and non-Yakunin. For the day was a Rei-bi, or visiting day, of which there are three in a month, and no work was doing, so that the *oi πολλοι* of Yokohama were amusing themselves much as the *oi πολλοι* of home amuse themselves under like circumstances. It is quite an error to suppose that intemperance is uncommon in Japan. And it is as great a mistake, and a very unjust one, to throw this sin upon the advent of foreigners. Here, at least, we are guiltless of introducing fresh evil; if, indeed, it were possible to add anything to the evils already in existence, the social evil and drunkenness, our two great stumbling blocks at home, being so well represented here; to which must be joined a third evil, from which we are happily free in Old England, a feudal despotism, with its accompanying laxity of justice and disregard of human life.* Further, the sale of alcoholic liquors and of opium to the natives is forbidden by a clause in the treaty.

I returned to the settlement some half hour after the sun had disappeared behind Fusi Yama, that was yet visible as a dark blue-grey conical mass, standing out in bold relief against the steel-lustrous zodiacal light that streamed along the western horizon; thankful that Fortune, who had brought me so far from home, had brought me, in compensation as it were, to so pleasant a land.

* Such oppression is, doubtless, not much felt by the rural peasantry. Their very insignificance in the eyes of the great seignours on whose lands they live, acts probably as a powerful protection to them. And the immense importance which the Japanese government attaches to a plentiful and regular supply of rice, causes the class of Hyakshoo, or farmers, to be regarded with considerable favour. Their rank is next after the Bushi, or military class.

TESTIMONIAL TO SIR JOHN LIDDELL. A testimonial, consisting of an elegant candelabrum and other pieces of plate, has been given to Sir John Liddell, K.C.B., by many of his brother officers, on the occasion of his retiring from official life. The plate presented bore the following inscription. "To Sir John Liddell, Knight Bachelor of the United Kingdom, Knight Commander of the Most Honourable Order of the Bath, Knight of St. Anne of Russia, Knight of the Redeemer of Greece, late Director-General of the Medical Department of the Navy, and an Honorary Physician to the Queen. In token of esteem from medical officers of Her Majesty's fleet, 1865." The testimonial was presented by Dr. Wilson; Dr. Bryson and many other medical officers of the navy being present.

CONTAGIOUS DISEASES AMONG SOLDIERS. In the House of Commons, on May 19th, Colonel North asked the Under Secretary of State for War what steps had been taken to bring into operation at Aldershot the Contagious Disease Prevention Act. The Marquis of Hartington replied that Dr. Leonard, the inspector under the act, had reported that the local hospitals were not suitable for the purpose. Under those circumstances, temporary arrangements were made to remove cases of this kind to the Lock Hospital in London. The very limited experience they had had in working the act had shown that, unless the provisions of the act were completely carried out, very little or no benefit whatever would result from the act. Dr. Leonard had proposed to carry out the act on a complete scale at Aldershot, and his plans were under consideration.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFRESON, M.B. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYDIE, F.R.S.Ed., Professor of Clinical Surgery in the University of Edinburgh.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
SOUTH MIDLAND. [Annual.]	George Hotel, Northampton.	Wednesday, June 7, 2 P.M.
LANCASH. & CHESHIRE. [Annual.]	Royal Institution, Manchester.	Wednesday, June 21.
NORTHERN. [Annual.]	Library, Newcastle-upon-Tyne Infirmary.	Wed., June 28, 10.30 A.M.

SOUTH MIDLAND BRANCH.

THE annual meeting of the South Midland Branch will be held at the George Hotel, Northampton, on Wednesday, June 7th, at 2 P.M.; GEORGE ASHDOWN, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, as soon as possible; or not later than the 23rd instant, to Dr. Bryan, Northampton.

JOHN M. BRYAN, M.D., } *Hon. Secs.*
G. P. GOLDSMITH. }

Northampton, May 15th, 1865.

LANCASHIRE AND CHESHIRE BRANCH.

THE Annual Meeting of the Lancashire and Cheshire Branch will be held on Wednesday, June 21st, in the Royal Institution, Mosley Street, Manchester; THOS. TURNER, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Honorary Secretary, without delay.

WM. ROBERTS, M.D., *Hon. Secretary*.

89, Mosley Street, Manchester.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

The Council of Management hope that gentlemen will prepare papers and cases, and forward the titles of the same to Dr. Philipson not later than June 17th. Dinner at 6 P.M.

G. H. PHILIPSON, M.B., *Hon. Secretary*.

BATH AND BRISTOL BRANCH:
ORDINARY MEETING.

THE sixth ordinary meeting of the session was held at the York House, Bath, on Thursday evening, May 18th; R. W. FALCONER, M.D., President, in the Chair. There were also present forty members and two visitors.

New Members. The following gentlemen were proposed and unanimously elected members of the Association and of the Branch:—Ebenezer Ludlow, Infirmary, Bristol; Francis Howes, M.D., Eastern Dispensary, Bath.

Papers. The following papers were read and discussed:—

1. Case of Necrosis of Clavicle. By A. Prichard, Esq.
2. Case of Rheumatic Fever followed by Pericarditis and Mortification of the Extremities. By Wm. Davis, Esq.
3. Case of Excision of Upper Maxilla. By H. Marshall, M.D.
4. On the Hypodermic Injection of Morphia. By H. W. Freeman, Esq.

EAST YORK AND NORTH LINCOLN BRANCH:
ANNUAL MEETING.

THE ninth annual meeting of this Branch was held at the Hull Infirmary on Thursday, May 18th, 1865, at 1 o'clock, under the presidency of ROBERT M. CRAVEN, Esq. There were also present seventeen members and five visitors.

Officers and Council. W. J. Lunn, M.D., was chosen President-elect; J. Fearn Holden, Esq., Honorary Secretary; and J. A. Locking, Esq., Honorary Treasurer. The following gentlemen were appointed the Committee for the ensuing year; viz., Sir Henry Cooper, M.D., Owen Daly, M.D., and Messrs. Sleight, Dix, Hawley, and Leppington.

Medical Provident Society. Sir Henry Cooper having resigned the office of representative of this Branch to the Provident Society, it was resolved that for the present no successor to Sir Henry Cooper be appointed.

New Member. Mr. Wm. Stephenson of Beverley was elected a member of the Branch.

President's Address. The PRESIDENT then read some very apposite and valuable observations on the present state of the medical profession, and on some of the more recent inventions in surgery.

Papers. The following papers were read.

1. A Case of Fibro-Cystic Tumour Cured. By John Dix, Esq.
2. Remarks on the Application of Blisters. By Owen Daly, M.D.
3. Mr. R. H. B. Nicholson gave two very interesting cases.

Dinner. The business of the meeting being completed, the members and visitors dined together at Glover's Hotel, where twenty-five gentlemen sat down to dinner, and brought to a most satisfactory close the best attended and most interesting meeting this Branch has perhaps ever held.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH. A special meeting of the Association will be held at the Scottish Corporation Hall, Crane Court, Fleet Street, this (Saturday) evening, May 27th, at half-past Seven o'clock. Dr. Clouston, of Carlisle, will read a paper on "The Production of Dysentery by Sewage Irrigation".

Correspondence.

A REASONABLE SUGGESTION.

LETTER FROM CHRISTOPHER JOHNSON, JUN., ESQ.

SIR,—I perceive in your paper to-day that you refer with approbation to a scheme propounded in the columns of the *Times* by Mr. Macdonald Stevenson, for the removal of fever cases to hospitals.

The evil which he desires to remedy has been met here in Lancaster in a far more simple manner. The authorities kindly presented to the Committee of the Lancaster Infirmary a secondhand roomy Clarence. The cloth lining was removed, and one of American oil-cloth substituted. This is kept at the infirmary, and is lent gratuitously; the patients' friends having merely to send a postboy and horse for it from one of the hotels. We had a sedan; but it was always evaded, on account of the notice it attracted.

Nine-tenths of first cases are kept in private houses, because the inhabitants fear the injury to their business that would ensue if it were known that fever was there. They are either kept at all hazards, or smuggled off in street-cabs.

A carriage with extra springs, India-rubber tires, and a *coupé* in front, may be a very ornamental and genteel affair; but it is not precisely the thing a tradesman would like to have standing at his shop-door. Hence I fear that the scheme of Mr. Macdonald Stevenson will not meet the difficulty.

A street-cab answers well every purpose. Why then aim at anything else? Why have a separate *coupé* for the attendant? A seat alongside the driver, or a dickey behind, would accommodate one person; which, with driver and patient, would be quite enough for one horse. A carriage to answer the purpose well may be purchased secondhand of any coach-maker for £10. It is not desirable to keep a horse, as that can always be obtained. I think that, if it were made compulsory to have such a carriage wherever there is a fever hospital, the sort of vehicle might be safely left to the selection of local authority.

I am etc.,

CHRISTOPHER JOHNSON, JUN.

Lancaster, May 20th, 1865.

CARICA PAPAYA: A VERMIFUGE.

LETTER FROM ROBERT DYCE, M.D.

SIR,—In the BRITISH MEDICAL JOURNAL for Saturday last (May 20th), there is a short paragraph at page 517 from the *Répertoire de Pharmacie*, respecting the experience of Dr. Viani, of the Island of Réunion, on the vermifuge properties of the juice of the "Papaw fruit". That this is no exaggeration I can bear my testimony, having had many years' experience of its virtues, now a long time ago, in the same island, where I was quartered as an officer on the medical staff of the army. I beg to refer you to a paper of mine on the subject of Lumbrici, published in the *London Medical Gazette*, vol. xiii, for the year 1834, page 866, where, amongst other remedies, I specially alluded to the juice of the fruit of the *Carica papaya* as a specific in that complaint. I then gave the method of procuring it, the dose, etc., and subsequent treatment.

Since that time I have made various attempts to get the juice brought to this country, by having it made into some extract or inspissated form, as at present it is only available in countries where it grows; but I regret to say that hitherto my efforts

have not been successful. A few years ago, I learned that the tree was common in the West Indies; and, through the kindness of Sir W. Jackson Hooker, was brought into communication with an eminent botanist in Jamaica, with whom I corresponded. Through his means and that of a resident chemist, I have had different preparations of the fruit, both ripe and green, the seeds, and latterly an inspissated form of the juice "dried in a steam-pan and sprinkled with alcohol", sent me for trial. Of this latter preparation, which seemed the most promising, I sent a considerable supply to my friend Dr. Murchison of London, requesting him to give it a trial. He writes me, a few weeks ago: "I have tried the papaw-juice in two cases of tapeworm; but so far it seems to be perfectly inert. In each case, three successive doses, of six drachms each, on an empty stomach, were administered, followed by castor-oil; but nothing came away except a few single joints, the same as had been coming away before." I fear, therefore, that the active principle must have been destroyed by the mode of preparation.

I may mention that I never saw it tried in tapeworm, as this variety does not, I believe, exist in the Mauritius; it is only the lumbrieus, and occasionally the ascarides, that are there such a pest. I have, however, no doubt but that the fresh juice, could it be procured, would be equally specific in the one case as in the other. I am, etc.,

ROBERT DYCE, M.D., F.R.S.E.,

Professor of Midwifery, University of Aberdeen.

Aberdeen, May 22nd, 1865.

Medical News.

APOTHECARIES' HALL. On May 18th, 1865, the following Licentiates were admitted:—

Fawcett, Thomas Joseph, Newcastle-upon-Tyne
King, John, Stratton, Cornwall
Oakley, John, Shrewsbury
Price, John Lowe, Cheltenham
Quin, John Hogan, North Street, Leeds
Shepard, William Lively, Gray's Inn Road

At the same Court, the following passed the first examination:—

Cremonini, John, Birmingham

APPOINTMENTS.

WATTS, Horace, M.D., appointed, by the Queen, Colonial Surgeon for the Falkland Islands.

ARMY.

BOULTON, Staff-Assistant-Surgeon E. J., to be Assistant-Surgeon Royal Artillery.

CAMPBELL, Staff-Assistant-Surgeon G. M'Iver, M.D., to be Assistant-Surgeon 67th Foot, *vice* R. Heard, M.D.

DEVLIN, Assistant-Surgeon H. W., Royal Artillery, to be Staff-Assistant-Surgeon, *vice* J. M. M'Lean, M.D.

HEARD, Assistant-Surgeon R., M.D., 67th Foot, to be Staff-Assistant-Surgeon, *vice* J. H. C. Whipple, M.D.

M'LEAN, Staff-Assistant-Surgeon J. M., M.D., to be Assistant-Surgeon 12th Foot, *vice* T. Walsh.

PARK, Assistant-Surgeon G., M.D., Supernumerary in 52nd Foot, to be Staff-Assistant-Surgeon, *vice* J. Wales.

WALES, Staff-Assistant-Surgeon J., to be Assistant-Surgeon Royal Artillery.

WALSH, Assistant-Surgeon T., 12th Foot, to be Staff-Assistant-Surgeon, *vice* G. M'Iver Campbell, M.D.

WHIPPLE, Staff-Assistant-Surgeon J. H. Connell, M.D., to be Assistant-Surgeon 21st Foot, *vice* H. O. Harvey.

MILITIA.

GRADHAM, C., M.D., to be Assistant-Surg. West York Rifle Militia.

STAFFORD, S. F. J., Esq., to be Assistant-Surgeon Norfolk Artillery Militia.

VOLUNTEERS, (A.V. = Artillery Volunteers; R.V. = Rifle Volunteers):—

CRAWFORD, J., M.D., to be Assistant-Surgeon 19th Lancashire A.V.

DOUGLAS, M., Esq., to be Assistant-Surgeon 3rd Durham R.V.

FOULKES, F., Esq., to be Surgeon 56th Lancashire R.V.

LOGAN, F. L., Esq., to be Assistant-Surg. 1st Northumberland A.V.

MORRIS, J. E., Esq., to be Surgeon 2nd Administrative Battalion Essex R.V.

OSMOND, T., jun., Esq., to be Honorary Assistant-Surgeon 16th Essex R.V.

SAVILLE, J. J., Esq., to be Assistant-Surgeon 8th Durham R.V.

DEATHS.

BUTT, William R., Esq., Surgeon H.M. Bengal Service, aged 38, on board the *St. Lawrence*, on April 14.

DUNLAP, James, M.D., at Windsor, aged 63, on May 21.

SHEPPARD, On May 23rd, at Neville Street, Brompton, aged 35, Hannah, wife of Walter G. Sheppard, M.D.

SCUMER, On May 14th, at 15, Wellington Terrace, St. John's Wood, aged 2 years, Frank Cecil, youngest child of W. Allen Sumner, Esq., Surgeon.

*WILLIAMS, Thomas, M.D., F.R.S., at Swansea, aged 46, on May 23.

NEW SOCIETIES. An Anthropological and Scientific Professional Society have been started at Madrid.

ETHNOLOGICAL SOCIETY. On the 23rd inst., the anniversary was held at St. Martin's Place; Professor Busk, F.R.S., Vice-President, in the chair.

EXTENSIVE SKIN-DISEASE. Dr. Fischer of Berlin relates in the *Berliner Klinische Wochenschrift* a case of tinea tonsarans affecting the whole body.

DR. JENNER. The Queen has given Dr. Jenner permission to wear the badge of Commander of the Order of Leopold, lately bestowed on him by the King of the Belgians.

A MEDICAL PREACHER. Mr. C. V. Cay, Surgeon of the Coldstream Guards, it is said, has lately preached in a chapel at Sunderland, where his father resides.

SIR CHARLES LOCOCK has issued an address intimating his intention of becoming a candidate for the representation of the Isle of Wight in Parliament. Sir Charles is a conservative in politics.

THE TRIAL OF DR. PRITCHARD is, according to the *Glasgow Morning Journal*, likely to take place in Edinburgh on some day between the 12th and 20th of June.

UNIVERSITY COLLEGE HOSPITAL. The late William Hollins, Esq., of Over Wallop, Southampton, has bequeathed to this hospital £500 for the formation of a fund to be called after the name of the testator.

MELBOURNE UNIVERSITY. At the last annual matriculation, the number of students who had passed the examination was thirty-five, of whom twenty-four were admitted, the rest being absent.

THE SUPERANNUATION BILL. This measure has passed its second reading in the House of Lords. The voice of the profession and its claims for consideration have been completely ignored. In not one sentence of the entire debate is the medical profession even mentioned.

PHARMACY BILLS. Dr. A. S. Taylor and Mr. Simon have been examined before the Select Committee of the House of Commons. The evidence of the former was mainly in support of a clause restricting the sale of the more dangerous poisons. Mr. Simon's evidence was to the same effect.

UNIVERSITY OF EDINBURGH. It is said that the trustees of the fund left by the late Dr. J. B. Gilchrist of Edinburgh for educational purposes, have decided on founding in the University of Edinburgh three scholarships of £100 a year each, to be held for three years by natives of British India, who shall have passed competitive examinations in the presidential colleges. These scholarships will be attached respectively to the medical, law, literary, and scientific classes, religious tests or distinctions being excluded. Similar scholarships, it is reported, are also to be attached to the London University College.

TESTIMONIAL TO DR. J. H. ROGERS. On his resignation of the honorary secretaryship of the East Grinstead Dispensary, Dr. Rogers has been presented with a testimonial by the friends of the dispensary. The choice of the testimonial having been left to him, he selected an elegant conservatory.

DEATH OF DR. VALENTINE MOTT. This celebrated American surgeon died on April 26th, in his eightieth year. In early life he was a pupil for some time of Sir Astley Cooper; and subsequently became distinguished as an operative surgeon and as a contributor to the literature of surgical science.

PUBLIC NEWSPAPERS AND QUACK ADVERTISEMENTS. It is gratifying to note, that the public journals have many or them lately refused to insert in their pages the filthy productions of the rascally advertising quack tribe. Nearly 250 newspapers in country and town have already thus honourably distinguished themselves.

MEDICINE IN BAVARIA. On February 3rd last, the King of Bavaria issued a decree permitting Bavarian doctors to settle where they pleased in his kingdom. It appears that, previously, a doctor after he had taken his degree, was ordered to fix his residence in that part of the country which the government thought most required his services. One could hardly have believed such tyranny had existed in an European kingdom at this time of day.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN. An adjourned general meeting of this Society was held at 53 Berners Street, on Wednesday evening, for the purpose of considering a new code of byelaws, drawn up by the directors since the reception of a Royal Charter by the Society. Several of the laws were carefully discussed and adopted; and the meeting adjourned for their further consideration until Wednesday, June 7th, at 8 P.M.

THE EPIDEMIC IN SAVOY still attracts some attention. General Morin states that there can be no resemblance between this disorder and the Russian fever, for in St. Petersburg they carefully avoid the use of iron stoves. In connection with the same subject, and the notion that the disease results from the presence of carbonic oxide in the air, Mr. C. H. Deville reminded the Academy that his brother had shown that red-hot cast iron allowed gases to pass freely.

THE NEW YORK NEW MEDICAL JOURNAL. Memory fails us in endeavouring to enumerate the various attempts to establish a medical journal in the city of New York. We have received the initial number of a periodical entitled *The New York Medical Journal*, it is generally understood that the position of *rédauteur en chef* is held by Dr. Hammond, late Surgeon-General of the United States armies. (*Philadelphia Medical Reporter*.)

MEDICAL STOCK-JOBBER. The *Philadelphia Medical Reporter* advises its clients as follows:—"United States 7-30 Loan.—By an advertisement in our columns, the readers of the *Reporter* are invited to invest any surplus cash they may have, in the great United States 7-30 Loan. In our view, this is the safest investment that can be made of capital, and it will be placing money not only in a safe place, but where it will be of advantage to the country and the world, for truly our country with its institutions is a power for good in the earth. We will cheerfully give our readers who cannot conveniently visit cities where there are agencies for this loan, such information as will enable them to make their investments, or we will transact the business for them."

FEMALE MEDICAL SOCIETY. This Society, established to form a Medical College in London for Ladies exclusively, and to promote the proper education of female medical practitioners, more especially for the purposes of midwifery, held its first annual meeting at the Ladies' Medical College, Fitzroy Square, on the 23rd inst. The Marquis Townshend presided. It was contended that the employment of superior women in the practice of midwifery and the treatment of the diseases of women and children was called for by the gravest social and domestic considerations; and that those departments in the practice of medicine would not only open up to women a wide field of honourable and lucrative employment, but would also prove valuable as a means of intellectual culture and social usefulness to ladies who may not be dependent upon their own exertions.

IDENTIFICATION OF THE DEAD. The *Alta California* of March 16th, reports that Dr. L. J. Henry, by the consent of the coroner of Alta, brought into use the process of Dr. Richardson of London for restoring the features of a dead man who had undergone such change from decomposition that he could not be identified. The man had been murdered and buried in a very shallow grave; the body was discovered from some animals having partly removed the earth. On the body being brought to the dead-house it was quite unrecognisable. Dr. Henry placed it in a water-tight shell, and then covered it (the body) with water containing twenty pounds of common salt and one pound of hydrochloric acid. After immersion for three hours, the body was removed; the face was washed first with simple water, then with chlorine water, and finally a free current of chlorine gas was passed over the face. After the operation, by which the face was bleached, the friends of the dead man were able positively to recognise him as one Charles T. Hill, and on this identification a man was arrested in whose possession various articles belonging to Hill were found, and who is believed to be the murderer. The restoring process seems in this case to have been entirely satisfactory, and to have served a purpose which a few years ago it would have been considered impossible to carry out.

IRISH LUNATICS. In the House of Commons, Mr. McEvoy lately observed that, of 16,600 lunatics in Ireland, 8,000 were confined in gaols, workhouses, and lunatic asylums. The management and treatment of lunatics, therefore, became an important question. There were at present in the gaols 669 who had been committed as dangerous lunatics. The retention of lunatics in gaols had been condemned by the inspectors. The health of the lunatics was not sufficiently looked after, and the discipline of the gaol very much impaired. Lunatics should be sent to proper lunatic asylums, where there would be a prospect of a large number recovering their reason. Sir R. Peel said that Government were doing their best to remedy the want of proper lunatic asylums in Ireland. When the six new asylums they were building, in addition to the sixteen already in existence, were completed, there would be no want of accommodation for lunatics. Even under the present arrangement, whenever a lunatic was certified by the proper medical officers of the gaols to be dangerous, he was, if possible, at once removed to a lunatic asylum. The Government were devoting the most anxious attention to that subject; and, in the course of less than three years, every one of the district asylums, with the single exception he had mentioned, would be completed, and there would be every accommodation for all the dangerous lunatics who either now or who might hereafter be committed to gaols.

SANITATION OF THE INDIAN ARMY. In a general order issued by Sir W. Mansfield at Poonah we read: "His Excellency would further beg the Principal Inspector-General, Dr. Stovell, and Deputy-Inspector-General British Troops, Mr. Canning, to accept his warm acknowledgments for the excellent manner in which they have presided over their respective medical departments, and the energy with which they have directed the efforts of the medical officers under their orders for the improvement of the health of her Majesty's troops and for the spread of sanitary reforms."

THE AMERICAN MEDICAL ARMY STAFF. At the beginning of the present strife, there were but 107 medical officers in the army of the United States. Now there are 500 commissioned officers of the medical staff, 2,000 physicians serving under contract, and a vast force of regimental surgeons and assistant-surgeons. The estimate of the expenses of the medical service of the army, for the year ending June 30th, 1862, was 115,000 dollars. For the year ending June 30th, 1863, the expenditure was 11,594,650 dollars. Everything which science, labour, or money could wisely attempt, has been accomplished.

PAUPER NURSES IN WORKHOUSES. The Poor-law Board has issued a circular to the guardians and directors of the poor, urging the discontinuance of the practice of employing pauper nurses. The circular says a nurse should be a person of experience in the treatment of the sick, of great respectability of character, and of diligent and decorous habits. It is necessary that nurses should be adequately remunerated, and that they should be appointed after a strict investigation of their qualifications for the office. The Board consider it of the highest importance that the assistants to the nurses should also be paid persons. Where pauper inmates are directed to act as assistant-nurses, there is no stimulus, no test of capacity, and no responsibility for negligence.

THE LATE DR. GALLOGLY. At a recent meeting of the guardians of the Clogheen Union, it was resolved—"That we, the guardians of the Clogheen Union, feel we ought not to separate without placing on record our estimate of the long-trying and faithful services of the late lamented Dr. Gallogly, whose connection with us commenced with the formation of the union, and terminated only with his death. During that long period, embracing two visitations of Asiatic cholera and the famine, Dr. Gallogly was never known to shrink from the performance of his arduous duties, but with zeal, Christian gentleness, and benevolence, dispensed his valuable services to the poor, justly winning from them gratitude and respect. Gifted with every attribute of a gentleman, as well as with professional ability, he was beloved and esteemed by a numerous circle of friends, who now deeply mourn his loss." (*Clonmel Chronicle*.)

NOTE-TAKING. Sir Benjamin Brodie says it was from his friend Jeffreys that he first learned the importance of keeping written notes of cases. All his life he kept notes. At the bedside of his patients he jotted down a few memoranda, which he afterwards expanded in the evening; and his notes of cases thus kept for half a century now form many quarto volumes. He did not find that the habit of committing his observations to writing weakened his memory, but rather that it strengthened it; and in the most strenuous terms he insists that no one can become thoroughly well acquainted with his profession, either as a physician or as a surgeon, who has not studied it in that manner. He has always tried to impress this fact on his pupils, and has often lamented that only a small proportion of them would follow his advice.

ROYAL COLLEGE OF SURGEONS OF IRELAND. The 5th of June has been fixed for the annual meeting of the Fellows of the Royal College of Surgeons to elect their representative Council; and, as usual, the same day has been named for the yearly assemblies of the Irish Medical Association and the Royal Medical Benevolent Fund Society of Ireland. A seat on the Council of the College will become vacant by the retirement of Dr. Hutton, whose health has become much impaired. A vigorous candidature is anticipated. At the expiration of the President's (Dr. Jacob) tenure of office, Mr. Wilmot will become President, and Mr. Butcher is mentioned as likely to succeed to the Vice-President's chair. The Irish Medical Association will meet for the discussion of topics of interest to the profession, and will dine together in the evening. A large meeting is to be desired, and, we believe, anticipated. The Royal Medical Benevolent Fund Society will hold its annual assembly on the same day, at four o'clock.

SCOTTISH REGISTRAR-GENERAL'S RETURN. The returns for the first quarter of the year 1865 show a high birth-rate in Scotland. The return of marriages also is satisfactory. The unsatisfactory thing in the quarter's return is, as in England, the mortality, which was still above the average. The population of Scotland was not healthy during the quarter. The weather was very cold, and proved most deadly to the aged. The notes of rural registrars are, in many instances, extremely remarkable:—"Seven of the eight deaths were of persons above 80." "All but two were above 68." "Of the ten who died half had exceeded their three score and ten years." "The youngest of the persons who died was 84." Both last year and this epidemic diseases have prevailed over all parts of the country, especially fever, and increased the mortality. Work has been plentiful, wages high, and provisions cheap; yet fever has raged as a true pestilence in towns where none need have been idle who were willing to work. It has come after Scotland had been enjoying for more than ten years a notable exemption from epidemics of fever. The present epidemic of fever first appeared in September 1863, and if it follows the course of former epidemics it will probably continue for a period of nearly three years from the date of its origination.

ST. MARY'S HOSPITAL, PADDINGTON. On the 23rd inst., the ceremony of laying the foundation-stone of the new wing about to be erected to this building was performed by His Royal Highness the Prince of Wales, in the presence of a large number of ladies and gentlemen. All the galleries and seats containing the spectators were profusely decorated with laurels and evergreens, and dressed with flags. His Royal Highness was received on his arrival, shortly after three o'clock, in the Board-room of the hospital, by the Vice-Presidents, Treasurer, Medical Staff, etc. An address was then read to His Royal Highness, which, after referring to the fact that the original foundation-stone of St. Mary's Hospital was laid by the Prince's lamented father, the late Prince Consort, proceeded to observe that, although St. Mary's was the youngest of the general hospitals and medical schools of London, it having been founded in a new and fast growing suburb, the requirements of the neighbourhood had already rendered increased accommodation absolutely necessary. The new wing was to include a chapel; and the Governors ventured to hope that it would be agreeable to the feelings of His Royal Highness if the new wing should be called after himself—the Albert Edward wing, and the two wards receive the names of the Alexandra and Albert Victor wards, the latter to be exclusively devoted to

the reception of children under the age of five years. The purses presented by the ladies and children on the occasion contained £279.

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
 TUESDAY....Guy's, 11 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
 WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
 THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
 FRIDAY.....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
 SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

WEDNESDAY. Royal College of Physicians, 5 P.M. Dr. Lionel Beale, "An Inquiry into the Nature of the Phenomena which constitute Inflammation."
 THURSDAY. Linnean.—Chemical.—Royal (Anniversary).
 FRIDAY. Royal Institute.—Western Medical and Surgical Society (Anniversary). Secretaries' and Financial Reports to be read; Officers for next Session to be elected: Practical Evening for Cases, etc.

TO CORRESPONDENTS.

* * All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

POOR-LAW MEDICAL REFORM.—SIR: I beg to enclose you a note addressed to each of the medical officers in this union, in order that your readers may see how much we, as a body, may expect to benefit by the recent recommendation of the Committee on Poor Relief.
 I am, etc., STAMFORD FELCE.

Launceston, May 23rd, 1865.

"Launceston Union, Launceston, 20th May, 1865.

"Sir,—I am directed by this Board to ask the question. What reduction you would be prepared to make in your salary in case the Board provide cod-liver oil as a medical extra?"

"I remain, your obedient servant,"

"S. Felce, Esq." "JOHN DINGLEY, Clerk.

MEDICAL ETIQUETTE.—A correspondent writes: "While I was attending a mild case of hæmoptysis in this village, the patient, being very nervous, wished a neighbouring practitioner to be called in, much my senior. He ordered a prescription, and called the next day, and examined the medicine. The following day, he brought a small ounce bottle of dark sherry colour (very clear) mixture, and in the presence of the patient produced it, and said: 'This is the kind of mixture it ought to be.' Do you think this etiquette a proper thing for a medical friend to do? I saw the case for two days afterwards, and then resigned it altogether, as I could find that my friend would continue to call. This is not the only case I have had."

LIEBIG'S EXTRACT OF FLESH.—SIR: In answer to your question respecting Liebig's Extract (Liebig's) in the JOURNAL of the 13th inst., I beg to say that I have always a supply on hand.

I am, etc., FREDERICK ANDREWS.

23, Leinster Terrace, Hyde Park, W., May 23rd, 1865.

THE GRIFFIN TESTIMONIAL FUND.—SIR: The following subscription has been further received on behalf of the above Fund:—Dr. W. W. Miller (Eye), 10s. 6d.

Amount previously announced, £121:1:3. Received at the *Lancet* office, £9:9.

I am, etc.,

ROBERT FOWLER, M.D.,

Treasurer and Hon. Sec.

115, Bishopsgate Street Without, May 25th, 1865.

TREATMENT OF CATARACT.—SIR: The accompanying letters on cataract and its successful treatment, induce me to request their insertion in your valuable columns; especially as three different surgeons have practised in three very similar modes for this ailment, with most satisfactory result: and, when it is remembered that the hazard of one operation—viz., extraction of the crystalline lens now usually adopted by oculists—is so frequently entirely destructive to the eye, whereas the operation of drilling the lens and "evacuating the aqueous humour", can be repeated a dozen times in hard cataract (if needful), with comparative little, or no pain or danger, and with perfect success. Furthermore, the patient is not required to undergo the present necessary confinement in a dark room after the extraction of the lens, or the skill of a few operators in an especial light room; but every surgeon, who can bleed, could perform the new plan in any room near a window. Thereby thousands of sufferers, who are now too nervous to submit to the confinement and pain, or have not the means to pay for the extraction of the lens, would be happily cured by a well established principle.

I am, etc.,

WILLIAM PARKER, M.R.C.S.,

27, Daniel Street, Bath, May 15th, 1865.

[COPY.]

To Sir David Brewster, Knight, Allerly, Melrose, Scotland.

Sir,—Having read account of your communication upon the cause and cure of cataract, at the last meeting of the Royal Society of Edinburgh, you will please to pardon my addressing you on such an important subject (by tapping the aqueous chamber), and forwarding herewith by same post statements of Mr. Jefferson, who has practised successfully on upwards of 7,000 cases, and myself on many, by drilling a hole in the crystalline lens.

I am, sir, faithfully yours,

WILLIAM PARKER, M.R.C.S.

27, Daniel Street, Bath, February 17th, 1865.

To Wm. Parker, Esq., M.R.C.S., Bath.

Sir,—I beg to thank you for your Lecture on Physiology. The operation which you have performed, by drilling a hole in the crystalline lens, is very interesting. M. Sperino has cured many cases of cataract at Turin, by my process of simply evacuating the aqueous humour, which I published many years ago. He has given an account of these cases in a volume published last year.

I am, sir, ever most truly yours.

Allerly, Melrose, May 6th, 1865.

D. BREWSTER.

COMMUNICATIONS have been received from:—Dr. JAMES RUSSELL; Dr. C. H. ALLFREY; Mr. R. S. FOWLER; Mr. STONE; Mr. A. B. STEELE; Dr. W. P. STIFF; Mr. J. Z. LAURENCE; THE HONORARY SECRETARY OF THE WESTERN MEDICAL AND SURGICAL SOCIETY; Mr. C. JOHNSON, JUN.; Dr. BUCHANAN and Mr. J. N. VINEN; Dr. B. W. FOSTER; Mr. EVANS; Dr. S. FELCE; Dr. JOHN THOMPSON; Dr. R. FOWLER; Dr. DYCE; Mr. HOLDEN; Dr. WM. ROBERTS; and Dr. MARSHALL.

BOOKS RECEIVED.

1. The Radical Cure of Extreme Divergent Strabismus. By James Vose Solomon. London: 1861.
2. Transactions of the Epidemiological Society of London. Vol. 11. Part I. London: 1865.
3. The Book of Prescriptions. By Henry Beasley. Third Edition. London: 1865.
4. On Diseases of the Throat; their New Treatment by the Aid of the Laryngoscope. By Thomas Dixon, M.D. London: 1865.
5. Sixth Annual Report of the Sussex Lunatic Asylum. Lewes: 1865.

I Lecture

ON THE

TREATMENT OF GASTRIC ULCER.

DELIVERED IN

Queen's College, Birmingham.

BY

BALTHAZAR W. FOSTER, M.D., F.L.S.,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS;
PHYSICIAN TO THE QUEEN'S HOSPITAL, AND PROFESSOR
IN QUEEN'S COLLEGE, BIRMINGHAM.

GENTLEMEN,—In to-day's lecture we have to consider the treatment of ulcer of the stomach; but, before doing so, it may be well for us briefly to review the condition of the diseased viscus. In all cases of gastric ulcer we have an ulceration of the lining membrane of the stomach of greater or less depth and superficial area, and with this in many cases we have more or less congestion of the mucous membrane in the neighbourhood of the ulcer, accompanied often by a state of catarrh. We have also irritability of the stomach; so great in some cases, that all food is rejected almost as soon as received; while in others, the ingestion of food causes intense pain, which, instead of being relieved by vomiting, may pass away only when the ingesta are transmitted into the duodenum. The viscus is thus either partially or almost completely disabled; and, as the proper performance of its functions is of vital importance to our patient, so the treatment that we adopt is necessarily of the highest moment. The existing conditions point out to us two grand principles to be followed; viz.:

1. To promote the healing process by removing all local impediments to the cicatrisation of the ulcer, and by aiding the constitutional powers.

2. To alleviate, as far as possible, the distressing symptoms of the disease. (*Vide Dr. Brinton, On Diseases of the Stomach*, p. 165. Second edition.)

Now, if we consider for a moment the offices which the stomach is commonly called upon to perform in order to support life, we must at once perceive how difficult it necessarily is to fulfil the first of the two great indications afforded us. And if we further think of the process of digestion, the chief symptoms of the disease—the pain, the vomiting, the hæmorrhage, the cachexia—cease to be only alarming, and become to the eye of the physician the almost necessary consequences of overtaxing a damaged organ. We cannot wonder that the stomach cries out in its clearest and most unmistakable manner whenever its surface is irritated by food, and refuses with all its energy to perform functions which, in their very process, irritate the disease that frets it.

If we analyse for a moment the digestive act, we at once recognise several circumstances interfering with the healing of the ulcer, which we may arrange thus:

1. The movement and great changes in volume of the stomach necessitated by the ingestion of food.

2. The mechanical and chemical irritation to the surface of the ulcer produced by the food.* (*Vide Dr. Budd, On the Organic Diseases and Functional Disorders of the Stomach*, p. 138.)

The very functions, then, which it is the duty of the stomach to perform, and which are essential to life, are opposed to a great extent to the healing process which we have to promote. Do not understand me to say that no ulcer can heal so long as the stomach is called upon to act, for such an assertion on my part would be opposed to clinical and experimental facts; but rather that the process of digestion interferes much, in cases of gastric ulcer, with the efforts made to repair the lesion. Consider how, in the case of a cutaneous ulcer, similar irritation would act; and how quickly the surgeon would set about removing all such obstacles to healthy action. In the pain caused by the irritating substances and the movements of the part would be discerned the voice of Nature calling for rest; and, on rest being obtained by the removal of all causes of disturbance, the healing of the surface-ulcer would quickly progress. Rest is as essential to repair as it is to growth; for repair is growth, directed, not to development, but to restoration. (*Vide Mr. Hilton's Lectures on Rest and Pain*.)

Let us bear in mind this great fact, then, in our treatment of internal ulcers; for we shall find that, in all cases of gastric ulcer, our measures must be chiefly directed to procure rest for the organ—rest from all mechanical irritation—rest from all physiological action.

Every attempt to digest food in severe cases of this disease sweeps away, more or less completely, the results of that curative process which has been going on during the previous state of rest, and leaves the ulcer, if no farther, still often as far from being healed as ever. Our great therapeutical agent in the treatment of this affection is, I am convinced, "mechanical and physiological rest" (*vide Mr. Hilton's op. cit.*); and as this is more or less perfectly obtained, so we may divide our remedial measures into those which obtain *partial rest*, and those which obtain the most *complete rest* at our command for the organ. The milder cases of this malady we may treat by *partial rest*; and this we may obtain by regulating the diet of our patient.

We must rule, however, both the quality as well as the quantity of the food, and prevent any distension of the organ, while we guard against any irritation of the diseased surface. Simple and well ascertained physiological laws must guide us in our selection of food. We must recollect that certain forms of nutriment are more easily digested than others; and also that some substances—*e. g.* protein compounds—specially require gastric digestion. Experience teaches that all food which takes much time and energy to be digested, or which is chiefly transformed in the stomach, proves most irritating to our patients. Animal foods, substances likely to irritate the viscus, hot ingesta, and particularly full meals, must be carefully avoided, as they all aggravate the patient's sufferings, and are frequently expelled. On the other hand, as we naturally might expect, bland food of an easily digestible form, of a

* I have not mentioned the action of the gastric juice as an impediment to the healing process, because I believe Dr. Pavy's experiments have proved that, under ordinary conditions, it has no corroding action on the surface of the stomach.

cool temperature, and in small quantities, is easily borne. (*Vide* Dr. Brinton, *op. cit.*, p. 183, 2nd edit.) In milk we have a fluid meeting all the requirements of the system, and at the same time possessing the qualifications above mentioned—at once the most easily digested and the most elaborately composed food. Sometimes, however, when taken alone, it is rejected; and in such cases it is often retained, if diluted with half its bulk of lime-water. This addition prevents more or less the action of the gastric juice upon it; and thus the milk is often passed into the duodenum, to be there digested. By regulating the quantity, however, we can usually ensure its favourable reception; and in many cases we find that the addition of the purer forms of starch, so as to increase its consistence, renders it much more grateful to the stomach. Arrowroot is the best form of starch to use at first. As the patient improves, corn-flour, sago, tapioca, and rice may be substituted; and thus the advance to more solid food most zealously guarded. The more easily digested forms of fish may be next allowed; and from these a most gradual return to the more ordinary forms of nutriment may be made. The greatest nicety of judgment, as well as the firmest control over your patient, must now be exercised; for a single excess will often produce a most serious aggravation of the symptoms. For some weeks after apparent convalescence must you guard your case; and the necessity of this is very evident, when you consider how easily the newly formed tissue covering the ulcer may be irritated.

Such is a brief statement of the treatment by *partial rest*, aided, of course, by such drugs as the urgency of any of the symptoms may require. I shall speak of these drugs in the latter part of the lecture, as their use is only occasionally called for. This treatment is what you may rely upon in the milder cases of the disease, such as we constantly see among the out-patients at the hospital; and you will generally have to adopt it in private practice. By it the stomach is favoured by *partial rest*; and the healing process gradually advances—slowly, however, on account of the frequency of the admission of food. In the severer cases of the disease, where the intense pain and tenderness point to probable perforation, where the irritability of the stomach causes all food to be rejected, or where hæmorrhage in large or moderate quantities indicates quickly advancing ulceration, I would rather have you obey the great principles which I have laid down more completely. I would have you obey as far as possible the indications which Nature shows you, and cease to irritate the organ by forcing it to receive food of which it as plainly as possible expresses its fear. The most rational and most successful treatment in such cases is to give the *most complete rest possible to the affected viscus by stopping the supply of all nutriment by the mouth, and supporting the patient for several days by nutritive enemata*. Perfect quietude in the recumbent posture must be observed; the lips and tongue moistened from time to time with a little water; and everything likely to excite the patient avoided. The body, thus placed in a position requiring the least expenditure of material, is easily supported for several days by enemata alone, even when the weakness of the patient makes the treatment seem hazardous. For eight or nine days the patient may be kept, if desirable, on enemata—even longer, if necessary; and during this time the pain, the irritability of the stomach, and of

the system, cease; and the sufferer enjoys ease to which he or she has long previously been a stranger. Far from becoming weaker, patients in general rally somewhat while under this system. When I first determined to try this method of treatment, I expected that great difficulty would occur in obtaining the cooperation of the patients; but I have found in all cases, with scarcely an exception, not only a willingness to submit to it, but scarcely a complaint during its continuance. The pain is generally so intense, and the patient, if hæmorrhage has occurred, so alarmed, that any treatment is willingly obeyed, especially one the *rationale* of which is so easily understood.

The substances which I have found most useful for enemata are milk, strong unsalted beef-tea, raw eggs beaten up in milk, occasionally a little brandy, and generally, in two enemata daily, ten to twenty minims of tincture of opium.* Feeding the sufferer thus, you gain for the stomach a few days' rest (generally six or seven); and then the symptoms have so much abated, that the treatment by *partial rest* can be adopted with success.

This interval of *complete rest* from all irritation—from all action—I consider of the greatest importance; and I have found it so beneficial in its results, that I would recommend you to treat all severe cases of this disease, whenever possible, by this plan. The ordinary method only partly fulfils the indications that present themselves; and in my opinion, and in my experience, renders the time occupied in the repair of the ulcer much longer. In the treatment by *complete rest* for a time, the patients rapidly advance towards health, and only remain under observation for about three or four weeks. A fortnight of restricted diet, after a week of perfect rest, is usually sufficient to restore the subject to comparative health. In all cases, however, it is essential to ensure, as far as in your power, a favourable form of diet for some short time longer.

I may here mention to you a case which, although not one of gastric ulcer in the ordinary acceptation of the term, nevertheless called for much the same line of treatment. I allude to a case of poisoning from a corrosive fluid (acid solution of chloride of zinc), now in No. 1 Ward of the Queen's Hospital. Gastritis and ulceration arising from causes like this you will often meet with; and, as I have in a previous lecture told you, they can be best treated by *complete rest*. This man had marked symptoms of gastric injury after he had recovered from the immediate effects of the poison. He was treated for some time on the restricted diet plan. The symptoms varied from time to time; but at last, after rather too full a meal, a severe attack of hæmatemesis occurred. Now thoroughly alarmed, he was glad to assist in any treatment that might prove beneficial, and for six days was fed by nutritive enemata given every two hours. From day to day he improved; the pain, the tenderness on pressure, disappeared; no hæmorrhage recurred; and when, after his long fast, he began his slight milk diet, no unpleasant symptoms followed. Ever since, the patient has done well, and advanced steadily towards health.

Cases of this kind, gentlemen, and the cases of gastric ulcer which you have seen treated in the hospital, speak more strongly and effectually than any

* The enemata should be as small as possible, from two to six ounces.

words of mine can in favour of a method of treatment which, by its simplicity and rational character, needs little argument to recommend it.

I have avoided as far as possible mentioning the drugs that are used for certain purposes in this disease, because I believe none of them are essential to us in promoting the first great object of our desire: I mean the healing of the ulcer. Certain symptoms, however, arise in the course of the malady; and, as in other diseases, the treatment of these symptoms forms often a great portion of our work. Rest for the organ has the effect of quickly diminishing the pain and allaying all irritability; and, if the rest be complete, these symptoms rapidly disappear. Perforation is best prevented by the treatment I have recommended; but, when it has occurred, the attention ceases to be occupied by the gastric lesion, and is concentrated on the resulting peritonitis. The hæmatemesis is, however, the symptom that we usually have to combat; and here, when it is copious, we often find drugs of great assistance. As we have usually time given us to check this hæmorrhage—for it is seldom immediately fatal—we can take a variety of measures to prevent its recurrence. When it occurs in small quantities, the recumbent posture, and rest as perfect as possible for the viscus, usually suffice to stop it. In most cases, ice in small rounded pieces may be swallowed. When the hæmorrhage is copious, I have usually found a mixture containing diluted sulphuric acid and gallic acid (ten minims of the former and five grains of the latter) in water, taken every two or three hours, the best remedy. Oil of turpentine—ten to twenty minim doses—has been strongly recommended. Acetate of lead with opium, alum, and tannin, may also prove useful.

As long as rest is observed strictly, the bleeding does not often recur; and this perfect rest, obtained as I have recommended, will usually be sufficient to prevent the return of this bad symptom. In treating patients, then, by the plan of *complete rest*, we not only place them in the most favourable position for the cicatrisation of the ulcer, but we also, for the most part, fulfil our second great indication—the alleviation of the symptoms. Certain medicines are, however, useful to us in this disease, not so much as curative agents as auxiliaries to our great therapeutic agent—rest. Opium has deservedly the highest position on the list, and you will find it in this affection most valuable. Not only in allaying pain, in soothing the general irritability of the patient, but also by its action as a stimulant, and by checking the waste of the tissues, do we find it most beneficial. Mr. Skey's observations as to its efficacy in the treatment of cutaneous ulcers are equalled almost by the general praise which it receives from all authors who have written on gastric ulcer. I have usually given it in the enemata to my patients, as thus we, in addition to its constitutional action, gain its soothing effect on the rectum, and prevent that irritability of the gut which sometimes interferes much with the treatment by *complete rest*. In some of the milder forms of hæmatemesis, if you cannot altogether stop ingestion of food, you will find good effect from this drug combined with kino, as in powder of kino with opium.

Tonics are needed during the period of convalescence, to remedy the cachexia; though this symptom, for the most part, begins to disappear as

the healthy condition of the stomach is restored. You will find the milder preparations of iron and quinine the best. I usually prescribe five-grain doses of citrate of iron and quinine, in infusion of calumba. This latter is probably the most useful vegetable tonic infusion at our command. In the anæmic state, often so marked in our younger female patients, the ammonio-citrate and the potassio-tartrate of iron may be prescribed with benefit.

Bismuth, since its introduction by Odier, has enjoyed a considerable repute in the treatment of stomach-diseases. In this affection, you will often find it useful as an auxiliary to your after-treatment, allaying as it does the irritability of the stomach, and checking the pyrosis. (*Vide Dr. Budd On the Organic Diseases and Functional Disorders of the Stomach*, p. 332.)

With regard to the use of *aperients*, I must warn you that they are only necessary, as a rule, in the after part of your treatment. Occasionally they are required in the earlier stages, but at all times should be of the mildest kind. Castor oil is probably the best, and may be given in enema, in which form all purgatives are best exhibited. Mercurial preparations prescribed to this end have, as Dr. Brinton has well observed, a most injurious effect.

You will find many authors vaunting the use of nitrate of silver. Let me remind you, as I have often done before, how useless the administration of a drug must be whose composition, if not changed long before its arrival in the stomach, is converted into an insoluble chloride immediately it reaches that viscus. Its stimulant action on the ulcer itself cannot be insured till we can directly apply the unchanged nitrate. "The careful system of diet, which is usually adopted in conjunction with the remedy, is itself sufficient to account for all the benefits observed." (*Vide Dr. Brinton, op. cit.*, p. 182.)

PRURIENT EXHIBITIONS. We hope that the case heard a few days ago at the Marlborough Street Police Court will have the effect of putting an end to the dirty and prurient exhibitions which are set up in London under the pretence of affording anatomical instruction. A gentleman went into one of these places in town and found it full of "disgusting models," so disgusting that the reporter states his description of them "is unfit for publication." A creature stands at the door of this den inviting the passers-by to walk in, and almost laying hands on them to compel them, while the immediate neighbourhood is infested by men who thrust loathsome bills upon everyone they can get near. There is a part of the Strand, and thence to Temple Bar, which is a disgrace to London during the day, and at night it is hardly safe to pass along it. It is thick with the scum of the town. Sir Richard Mayne would be doing a public service by ordering more vigilance to be used in this part; and as for the detestable exhibition which pollutes the thoroughfare, if it cannot altogether be removed, surely the pavement can be kept clear of the vagabonds who are touting for the spirits, more evil than themselves, inside. Thousands of poor creatures are being driven about from hole to corner in order to make our streets respectable, while indecency is thus openly advertised and proclaimed. If the police did their duty, the nuisance could at any rate be so reduced that it should not be an insult and an offence to every one who walks by the doors. (*Pall Mall Gazette*.)

OF

HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

ROYAL PORTSMOUTH HOSPITAL.

DISLOCATION OF THE KNEE-JOINT.

Under the care of E. K. PARSON, Esq.

J. B., aged 74, a strong muscular old man, was admitted on March 2nd, with dislocation of the knee-joint. The accident occurred as follows. The patient was descending a step-ladder; his foot slipped, and, catching between the steps, the knee-joint was twisted with considerable violence; the head of the tibia was thrown outwards; the internal condyle of the femur pressed inwards against the skin, threatening momentary protrusion. There was considerable deformity, making the nature of the accident easy of recognition at a glance. Reduction was effected in the following manner. Two assistants, grasping the leg near the ankle, made extension; another steadied the femur; while the house-surgeon, passing both hands round the head of the tibia, pulled it strongly inwards. It slipped into its place with a jerk. There was some swelling afterwards; and an evaporating lotion was applied. The patient was discharged twelve days from admission, with perfect use of the joint.

As this is a rare accident, it may be of some interest to note it. The reduction of the dislocation is not easily effected. Contrary to what we read in surgical works, considerable force must be used in extension to bring the bones into their natural position.

AMPUTATION OF THE THIGH.

Under the care of H. B. NORMAN, Esq.

W. M., aged 22, was admitted March 24th last, with disease of the knee-joint of nine years' standing. Amputation of the thigh was performed two days after the patient's admission; and, as is usual in such cases where the cause of constitutional irritation is removed, his improvement was immediate; and he was discharged in thirty-eight days from admission, vastly improved in health, with the wound completely cicatrised.

The operation was of the flap kind. Silk ligature was used to tie the femoral artery; thread for the smaller vessels. The flaps were brought together with iron wire; and a piece of wet lint was applied to the wound. This is the usual and only dressing applied after amputation in this hospital; no roller is used; but the stump is placed on a carefully arranged pad or pillow, which affords an uniform support, and serves every useful purpose.

Amputation of thigh was performed by Mr. Fergusson at King's College Hospital on May 6th; and, as there are some interesting and novel points in the mode of operating, they are reported here for the consideration of the profession. The patient was a woman who had been some time afflicted with a large tumour springing from the inner condyle of the right tibia; and, as she was suffering from intense pain

and considerable constitutional disturbance, it was deemed that amputation was the only sure means of giving her relief. The operation was performed as follows. The patient being chloroformed, an assistant compressed the femoral artery as it passed out under Poupart's ligament, no tourniquet being used. Mr. Fergusson raised the diseased limb nearly at a right angle with the patient's body for about two minutes; he then transfixed the thigh directly in front of and close to the femur, about three inches from the patella, bringing the knife out obliquely downwards. He proceeded in a similar manner at the back of the thigh, making as it were two short flaps. He then divided the tissues close to the bone, while an assistant made retraction. The bone was sawn off about three inches higher than where the knife first passed in; the vessels were then secured, and the flaps brought together with silk ligatures. The wound made but one line, as in the circular operation; and very little blood was lost. Strips of wet lint were then applied to the stump, and a roller over all.

Mr. Fergusson made the following remarks. He said that, after a large experience, he thought it better, in amputation of thigh, to depend on compression of the main artery by the finger of an assistant, than to trust to a tourniquet. It might have been also observed that he raised the limb for a short time, so as to unload the vessels, as it was of importance that as little blood as possible should be lost by the patient in her weak condition. The consequence of this proceeding was satisfactory; not more than an ounce of blood was lost. There were two modes of operation for amputation of the thigh, usually styled the flap and the circular; and he was of opinion for some time that a modification of each could be used, as in the present case, with very great advantage. It may have been observed that he transfixed the limb as in the flap operation, bringing the knife out obliquely downwards; and that he divided the tissues adherent to the bone, as in the circular operation; while retraction was made by an assistant. The consequence was apparent when the flaps were brought together. We had a wound in one straight line, getting rid of the side wounds, which very often extended three inches up the stump in the ordinary flap operation. He thought that this mode of operating would be found to be a great improvement on the old methods.

VENTILATION IN FEVER. Dr. MacCormac of Belfast thus writes on this subject to the *Dublin Medical Press*. "If Dr. Kennedy will come to Belfast, I will show him hundreds, if not thousands, of persons, of both sexes too, myself inclusive, who keep their windows open all night through, in all seasons, and with every possible advantage. I kept the windows entirely out during the treatment of cholera, and with the utmost benefit. I never treat a case of fever, at whatever period of the year, without opening the window and keeping it open day and night—a degree of exposure which Dr. Henry Kennedy affirms to be impossible. Persons in fever do not commonly labour under cold and livid feet, with cool breath and pulseless wrists. The hot stage is of a certain duration. There are also hot months in the year, during which the absence of ventilation entails, if possible, yet greater evils than during the cold. I never found the least difficulty in maintaining warmth along with open windows in fever. It is a perfect matter of notoriety, that fever cases by the roadside recovered oftener and better than in hospitals with the closed windows. Dr. Kennedy says he does not see how wards are to be kept dry. To which I reply, it is simply by not wetting them."

Original Communications.

ON AZOTURIA.

By EDWARD H. SIEVEKING, M.D., Physician to
H.R.H. the Prince of Wales, and to
St. Mary's Hospital, etc.

OF late years it has become the fashion to deny the existence of such a malady as the one to which Dr. Willis gave the name of azoturia. But, if the prominence of a particular symptom may determine the nomenclature of disease, it appears to me that the term in question may readily be justified. I have often in conversation discussed the matter with medical friends, and have stated my opinions; but have avoided any publication of them, because, though satisfied in my own mind, I felt that the evidence I had to offer was not so complete as the bio-chemist of the present day demands. I may at once state that the evidence I have to offer is defective in this way: modern analysis requires that, in order to determine the real excess of urea, the urine of twenty-four hours should be collected and measured; without which proceeding it is affirmed that the absolute quantity of urea passed cannot be fixed. I have no desire to set any limits to accuracy and minuteness of analysis, and feel assured that perfect correctness can only be attained in the way indicated. At the same time, the practitioner, in dealing with cases in private practice, and especially with cases that are only seen occasionally and at long intervals, is compelled to use comparatively coarse modes of estimating; and, if his statements are made with the necessary reservation, he may hope to advance the truth, though in a less perfect manner than is in the power of those capable of adopting a more perfect method.

Although I do not doubt that many cases of azoturia occur among the poorer classes, their maladies generally assume a more tangible character; and until the out-patient system of hospitals and dispensaries is revised, it will be impossible for the physicians to devote that care to their investigation which is necessary for the present purpose. Dyspepsia or anæmia are terms that cover a multitude of diseases, which a greater refinement of diagnosis would readily reduce to some other denomination.

While admitting the imperfection of my analyses, I cannot but think that, if we find a patient habitually passing urine of a high specific gravity, averaging 1030, and not due to the presence of sugar, nor associated with albumen, and proved to contain a very large amount of urea, we are justified in terming his case one of azoturia; the more so, if on close inquiry, no tangible disease can be detected to which the accompanying symptoms are referrible.

It has been my lot to have met with numerous cases of protracted indisposition, accompanied by defective powers of assimilation, irregular digestion, debility, general and indefinable *malaise* and more or less emaciation, though this not always, in which I held the excessive waste of the nitrogenous tissues, as indicated by the increase of urea in the urine, to be an adequate explanation of all the phenomena. The diagnosis was, in part, attained *par voie d'exclusion*; but after satisfying myself of the absence of all other sources of the morbid feelings of the pa-

tient, it appeared that a persistent and palpable feature, such as the one alluded to, would justify the application of Willis's term. Dr. Prout (*On the Nature and Treatment of Stomach Diseases*, 1848, p. 94), who gives a description that in most points tallies with my own observations, distinguishes between two forms of the disease; in one of which there is diuresis; while in the other there is an excess of urea without diuresis; and he regards the affection as analogous to diabetes. He considers that he has the strongest presumptive evidence, both from observation and analogy, that, if permitted to proceed unchecked, or if injudiciously treated, it passes into diabetes or some other formidable disease, though he has no positive proof of such termination.

I have at present under observation the case of a gentleman, in whom there is an alternation of azoturia and glycosuria; though, in neither case, is there a secretion of urine justifying the term diabetes. The amount passed rarely exceeds three pints in the twenty-four hours; but, while at times the urine is almost solidified by the addition of equal parts of nitric acid, owing to the formation of nitrate of urea, at others it is found to contain a palpable amount of sugar, as confirmed by the examination of my friend, Dr. Matthiessen, the lecturer on Chemistry at St. Mary's Hospital.

I have shown elsewhere, that an excess of urea is, as was already shown by Dr. Prout, a frequent accompaniment of epilepsy—an exhaustive condition which might have been predicated *à priori*, if *à priori* reasoning were of any value in determining natural phenomena. The occurrence, however, is not uniform; in fact, it fails with sufficient frequency to have induced one writer to assert that the characteristic feature of the urine in epilepsy was an absence of urea. Dr. Parkes, in his admirable work on urine, states that he has never met with a case of genuine azoturia, though he admits the possibility of its occurrence, as he quotes a case examined by Dr. Ringer, in which a man who was not febrile, and only appeared feeble, passed no less than 1130 grains of urea in each twenty-four hours, or about three times the average secreted by an adult male. It is of such cases, and not of the coincident occurrence of an excess of urea in other diseases, as in epilepsy, that I am now speaking; and I cannot but think that, were a special series of volumetric analyses undertaken to determine the point, the view originated by Prout would receive more positive support than it yet has, and azoturia would be definitively accepted as a member of the nosological fraternity. It is possible that Golding Bird, who laid what I should regard as an undue stress upon the presence of oxalates in the urine, because they come and go like will-o'-the-wisps, often spoke of cases of azoturia when he discussed his hobby oxaluria. He admits that, in oxalic urine, the density increases with the quantity of urea, which is often present in large excess. Indeed, he continues, "I regard the presence of a greater or less excess of urea almost as characteristic of the morbid state of the urine for which I am contending, as the oxalate of lime itself." (*Urinary Deposits*, 1857, p. 241.) Without controverting Dr. Bird's statement, I may state that, in the cases of azoturia as I have observed them, this balance between oxalates and urea has not presented itself; and, in fact, I may say, that the oxalates have but rarely occurred with the excess of the latter substance.

The following is a case to which I should apply the term, azoturia.

A gentleman, aged 53, but looking much older, consulted me in January 1861. He had always been very temperate, and had enjoyed good health till after an affray with poachers ten years previously,

when he had an attack of jaundice. He recovered from this, and remained well till, four years ago, he became subject to bilious attacks accompanied by irregular action of the bowels. Three years ago, after much annoyance and mental excitement, he suffered from carbuncles on his back. Since that time he had been in bad health; suffering from a feeling of numbness in the left leg, and occasional severe attacks of diarrhoea. He complained of occasional neuralgic pains, and at times entire absence of sensation in the left foot. He walked into my room like a man debilitated by disease, but in no way resembling a paralytic. He complained of having been affected with seminal emissions. I examined him very carefully afterwards in bed, and could find no trace of loss of parallelism or loss of motor power. I could not satisfy myself, by the æsthesiometer, of any material impairment of tactile sensibility; no tenderness of the spine and no abdominal derangement were traceable; nor was there any disease of the rectum or prostate. I commenced the treatment with steel, and the application of an anodyne liniment; and ordered wine, beer, and nutritious food. The patient, being a teetotaler, was with great difficulty persuaded to take any fermented liquors. I obtained a specimen of the morning and evening urine before my next interview, when I had a consultation with a leading physician on the case. Both specimens had a specific gravity of 1035, were strongly acid, exhibited no increase of phosphates, and contained neither sugar nor albumen. There were no crystalline forms in either, and specifically no oxalates; but both specimens almost solidified on the addition of equal volumes of nitric acid, by the formation of nitrate of urea. The joint examination elicited no proof of any organic disease; and it was agreed that the case was one of azoturia. The quantity of urine never was large that was passed in the twenty-four hours; it rarely attained to three pints. I find that on one occasion I had the advantage of obtaining a volumetric analysis from Dr. Ringer; and the estimate was seven drachms and a half in the twenty-four hours—an amount considerably above what Dr. Parkes considers the average in the healthy adult. The gentleman remained under my treatment for three weeks; and improved materially under the administration of mineral acids, opiates, and tonics of various kinds. It was not till after twelve days' observation that I discovered a few oxalates in his urine. In a medical report which I gave the patient at his request, on leaving town, I stated that I regarded the azoturia as the source of debility; and that the drain caused by a persistent waste of tissue, indicated by an excess of urea is the urine, sufficiently accounted for the anomalous nerve-symptoms to which he was liable.

I saw the same gentleman again at the end of 1862, when he was passing through London after he had, without medical advice, been taking the waters of Kissingen, and thereby brought on severe diarrhoea. He was naturally weak in consequence; but the urine presented a specific gravity of 1025—lower than I had ever seen it formerly, and I have a memorandum that it contained but little urea.

There are many insidious morbid conditions for which we may find an adequate explanation in the urinary secretion, with important hints as to treatment and regime. The insidiousness of degenerative renal disease as indicated by albumen, is a point that can scarcely be too often mooted; and it is surprising how often and how long patients continue ailing and complaining of feebleness and want of power without presenting any very tangible symptoms, when an examination of the urine reveals the cause of the anæmia, the weakness, and the apnoea,

and at once suggests the proper indication. Although albuminuria is a much more frequent cause of these insidious symptoms than azoturia, still I am satisfied that there are numerous cases of chronic disease going through a weary life, for which the undue waste of the nitrogenous tissues indicated by a high specific gravity of the urine and an excessive proportion of its urea affords a satisfactory explanation.

ON SYPHILITIC ULCERATION OF THE PALPEBRAL CONJUNCTIVA.

By JOHN WINDSOR, Esq., Consulting Surgeon of the Manchester Eye Hospital.

OF the secondary symptoms of syphilis, there is one which appears to have been rarely observed by writers on this subject, or, if observed at all, to have scarcely attracted particular notice or description: I allude to an ulcerated state, evidently, from its history, of syphilitic origin, appearing on the palpebral conjunctiva, and generally involving the adjoining tarsal cartilage. It is certainly an affection, as compared with other secondary symptoms, of rather rare occurrence; and in my own practice, of now a long duration, I do not remember (excluding, perhaps, two or three instances of it in congenital syphilis) to have met with more than about seven or eight cases; and of these, two of which occurred recently, I am enabled to add a brief report. Before doing so, however, I wish to premise a few remarks.

The subject of syphilis has for a long time, but more especially at a comparatively recent period, attracted considerable attention and research, both in this country and abroad; from which, I believe, a more correct knowledge of the specific distinctions of the disease has been acquired than was previously possessed.

At the present time, the conclusion arrived at seems to be, that there are two forms of primary syphilitic ulceration. One is the soft suppurating sore, sometimes accompanied, or soon succeeded, by enlargement, and not unfrequently suppuration, of the adjoining inguinal glands, but not contaminating the system, although communicable to others, and capable of reproducing repeatedly, by inoculation, similar sores in the same or in a different individual. It may be observed that occasionally, from some inflammation being excited, a degree of hardness is produced even in this form, but still distinct from the circumscribed and generally characteristic induration of the other.

The second form is the indurated sore, sometimes called the Hunterian chancre, the character of which is, in the first place, the secretion of an adhesive material, fibrine instead of pus (which latter occurs in the other form); thus appearing at first often rather as a pimple or hard tubercle, than a pustule. With this second form there is also not unfrequently some indurated enlargement of the adjoining inguinal glands, but it is not apt to undergo a suppurative process. This second form is the one which infects the blood; enters into the patient's system, producing secondary symptoms; and, although communicable to others, is not autoinoculable, except in its earliest period, before the adhesive effusion takes place. It, as a rule, occurs only once during life; whilst the first form may occur many times.

The first form I would compare to the *porrigo* (*impetigo*) *larvalis* (Willan), which, by contact, is often conveyed from one part of a child to other parts, or to those of its nurse. The second form I would rather compare, as infecting the general constitution, and mostly occurring once only during life, to small-pox, although

differing by the virus of the latter being in a great degree speedily eliminated from the system. Like small-pox, also, it has a period of three to seven weeks, or more (according to Mr. Henry Lee), of incubation, before the characteristic circumscribed hardness appears in the original fissure, abrasion, or pimple; and we know that another period intervenes before the appearance of secondary symptoms.

It seems possible that these two forms of syphilitic ulceration may coexist in the same person, and thus be communicated simultaneously to another; and thus, probably, the appearance of a pustule, not attended by a period of incubation, may sometimes precede the development of the true incubated chancre.

The first, or soft suppurating sore, is curable without the use of mercury, and its specific character may be generally effaced by the early application of caustics. The second, or indurated infecting sore, along with its secondary constitutional symptoms, or, as not unfrequently occurs, in its congenital hereditary form, yields to the action of this valuable medicine, administered seasonably, moderately, and cautiously, according to the circumstances or peculiarities of each case. For our present more precise knowledge of syphilis, we are especially indebted to the researches, experimental and practical, of Mr. Henry Lee, as shown in his recent work on *Syphilis*; although, doubtless, there have been other able coadjutors, both domestic and foreign, in the investigation of this important subject.

With regard to the more immediate subject of this paper, it seems, as far as I know, that Mr. Lawrence was the first to give an accurate description of it, as published in his work on *Diseases of the Eye*, as also in his work on the venereal disease of that organ. It has been since mentioned in the works of Mackenzie, and also of Middlemore, on the eye; and in the manual of Wharton Jones; perhaps, also by others; but I do not see it mentioned in Travers's excellent *Synopsis*, nor in Morgan's *Lectures on the Eye*. Neither have I seen any account of it in Scarpa's or Weller's works on the diseases of the eye. It is adverted to in Desmarres's, and also in Déval's, *Traité des Maladies des Yeux*; but not in the earlier works of Demours or Desmonceaux; nor is it noticed, I think, except very slightly, by Carmichael of Dublin, or Sir Charles Bell; nor in the comprehensive work of Langston Parker (third edition) on *Syphilitic Diseases*; yet Mr. Parker notices particularly the frequent occurrence, in secondary syphilis, of inflammation and ulceration of the mucous membrane investing the nares.

Some of the first examples of the affection which I had an opportunity of seeing occurred in persons whose cases I have recorded as instances of the phagedenic form of syphilitic ulceration; and the sores appearing on the palpebral conjunctiva are noticed incidentally, as seen in a subsequent period of the progress of the disease. Indeed, at that time (1821) my attention had not been particularly directed to the subject; and the first edition of Mr. Lawrence's work, containing his remarks on it, was not published until 1833.

CASE I. I was called on May 16th, 1825, to a gentleman named R. Allen, on account of a rheumatic affection. At the same time, a hard tumour, of about the size of a pea, presented itself near the frænum penis, which gradually became more inflamed, and afterwards ulcerated; the ulceration soon extending much over the part between the prepuce and the glans, forming a very large irritable sore, with hard ulcerating edges. In this state it proceeded for a few weeks; and then, after the continued use of decoction of sarsaparilla, aperients, and

milk diet, with rest, it began to assume a healing aspect, and was nearly well, when he irritated it by exposing himself to a fresh infection; but, by persevering in the same treatment, it again presented a healthy healing appearance, under the application of poultices and mildly stimulating mercurial ointments. On August 12th, it was nearly well; and an eruption on the forehead, which had troubled him for about six weeks, had also disappeared, excepting the marks, under the same treatment. Recently, however, the disease had reappeared in the form of five or six blotches on the forehead, of a circular form, of about the size of a sixpence, or smaller, flat in the centre and elevated at their margins, all of a coppery red colour; one on the head, amongst the hair, discharged matter occasionally from under a crust; and one on his forehead was nearly in the same state. There were two or three smaller eruptions on his face, in the form of acne or ecthyma. He continued to take decoction of sarsaparilla; and a solution of hydrargyrum corrosivum sublimatum was applied.

Oct. 1st. The eruption on the head and face was nearly well. For the last fortnight he had complained of his throat, which, on inspection, looked rather red, but was not ulcerated. The sore on the inferior part of the glans, or rather on the corpus spongiosum behind it, continued open, but had a clean healthy appearance.

Nov. 12th. He called upon me. Having gone out much during wet cold weather, and also living rather irregularly, he was not so well; his throat had become ulcerated on both tonsils, and on the posterior part of the pharynx, with hoarseness and some cough. The eruption on the skin continued better; the sore on the penis about the same. His pulse was accelerated; his appetite and general health indifferent. I directed him to stay at home, and to live much on milk diet; prescribing him pills twice a day of extract of conium and rhubarb (sing. gr. ij); and decoction of sarsaparilla with dilute nitric acid after each dose; also to use frequently a gargle of oxymuriate of mercury with tincture of myrrh and rose-water.

Nov. 19th. A sore (serpiginous), which he had had on his forearm, was now healing from the centre, whilst its margin was yet rather ulcerating. The sore on the penis was healing in some parts from its edges, but in others was rather ulcerating. His throat was about the same. A very large abscess, formed in the perineum in consequence of a blow on the part, discharged freely. A few scattered spots appeared on the trunk, but were scarcely ulcerating.

Nov. 27th. He was in nearly the same state. The phagedenic or serpiginous sores were still rather extending. The tonsils and posterior part of the pharynx were almost covered with ulcers. *One also, for the last ten days, had formed under the superior palpebra of the left eye.* That on the penis was extending at the margin, although healing at its middle. That on the arm was cicatrised, but was red, hard, and elevated. There were several sores on his body, but there was scarcely any discharge from them. The sore from the blow in perineo seemed healthy, but was still large. The sores on his body were dressed with resin cerate, and those in the throat were touched once or twice a day with oxymel æruginis. The other medicines were continued.

Dec. 18th. The oxymel æruginis, with an equal quantity of water, the parts being washed immediately afterwards, seemed to have had a good effect on the sores of the throat, penis, forearm, and conjunctiva palpebræ; and all of them appeared healing, as was also slowly that of the perineum. The pulse was still frequent, and the appetite indifferent.

Dec. 28th. The sore on the penis, after being open

nine months, was now just healed. The throat and other parts were also rather better, and his general health was a little improved.

Jan. 1st, 1822. About a dozen scabbed sores existed on the back and right side of the trunk, varying in size from that of a sixpence to a shilling. I prescribed him hydrargyrum cum creta and rhubarb (sing. gr. iij) three times a day, with an antimonial demulcent mixture.

Jan. 30th. He was nearly in the same state. Another small ulcer, which had appeared under the same palpebra, but rather nearer the external canthus, was touched with the oxymercurinis.

Feb. 18th. The conjunctival lining of the superior palpebra was nearly healed, but appeared of an unequal white and red colour, and was not perfectly smooth. The throat also appeared rough and ulcerated in points. Small ulcers on the penis alternately healed and broke out again. The incrustations on the trunk were in general falling off, but some formed again. His general health seemed rather improved.

April 20th. The state of the throat, conjunctiva, penis, and perinæum was about the same; and the cutaneous incrustations continued in the same state. He had some cough, and a little œdema of the lower extremities towards night.

June 4th. The palpebral conjunctiva continued a little red and rugose, but not ulcerated; the other parts were much the same. The cutaneous scabs had in a great measure fallen off. The cough and œdema of legs were nearly gone. Pulse frequent; appetite and sleep moderate. He walked out now a little almost daily.

June 21st. The palpebral conjunctiva of the left eye was again ulcerated; that of the right one had also latterly become affected, first by a few enlarged vessels appearing, which soon increased so as to produce a dense red spot, the precursor, probably, of ulceration. Numerous scattered spots of acne or ecchyma, with a yellowish suppurating point, had appeared nearly all over the body, producing much soreness. The throat was also in the same ulcerated state as it had been occasionally before. For the last four or five weeks he had been using, by his own desire, a mild mercurial course; but during this time there had been rather an aggravation of his complaint.

July 15th. The eruption was rather worse than better, affecting the face (especially the nose, which was almost covered with scabs and ulcers), the head, back, arms, and indeed the whole surface of the body. Some of the ulcers were covered with large crusts; others were discharging, and requiring to be dressed. The throat, palpebral conjunctiva, perinæum, and penis were much in the same state as before. I desired the mercury, which had been taken lately in very minute doses, to be entirely omitted; and ordered him to take only a mild aperient pill, and the decoction with acid as before.

Oct. 30th. Since last report, he had been staying in Liverpool; and during that time had been chiefly under the care of Dr. Macartney, who prescribed for him compound decoction of sarsaparilla, with an addition of extract of sarsaparilla, three tablespoonfuls three times a day; one-eighth of a grain of bichloride of mercury three times a day; and six minims of liquor arsenicalis three times a day; also antimonial powder, with extract of conium and opium, each night; and black oxide of mercury for fumigation. He also took twice a day a pill of two-thirds of a grain of black oxide of mercury, with ten grains of compound chalk powder and a grain of opium. The warm sea-bath was tried, but it seemed rather to increase the eruption. At present he was much better. The scabs had in a great measure fallen off, leaving

the parts healed. The ulcers of the conjunctiva were healed; the penis also. The throat was better, and the perinæum was healing. His general health was improved. Pulse natural; appetite moderate.

Dec. 6th. The pills and arsenical drops had been continued; but, some diarrhoea having come on, I desired him to discontinue them for a short time. A spot of ulceration, of about the size of a split pea, had appeared on the velum pendulum palati. He was prescribed half a pint of compound decoction of sarsaparilla twice daily, and to use the gargle as before for his mouth and throat.

Feb. 20th, 1823. About three weeks since, whilst there was a very severe frost, he continued to go out daily. Calling upon him at this time, I found the throat, tonsils, uvula, and pharynx presenting a sloughy appearance. Two sores upon the front of his leg had also a nearly similar aspect. His pulse was frequent, but his appetite tolerable. I desired him to keep the house, to live pretty well, to use his gargle warm, and to apply to his leg a linseed poultice. In about a week, the throat became cleaner; the greater portion of the uvula, sloughing off, came away. The ulcers on his leg had a sloughy and ulcerating appearance. I desired the linseed poultice to be exchanged for a bread and milk one, which immediately effected a favourable change, the sores assuming a granulating state, and soon beginning to cicatrise. His general health again improved. The conjunctival sores healed; those of the penis and perinæum nearly so. His skin was pretty free from tuberculous or ecthymatous eruption, but almost covered with large cicatrices.

March 27th. He continued better as to the external complaints, these being confined to a few small clean ulcers on his legs; but he had now become decidedly the subject of ascites, with œdema of the lower extremities.

Having already related this case so much at length, I will refrain from further details, only stating that, by the means adopted, the dropsical symptoms were removed.

March 1825. After the last report, he had a return of tuberculous or acne-like eruption all over his body, with much headache and some sore-throat; but he had now for some time been in tolerable health, only he was considerably altered in his appearance by the very long duration of his illness and the numerous cicatrices on his face.

Since reading the work of Langston Parker, I am inclined to think that the disease would probably have had its course arrested by larger use of some mercurial fumigation.

Having dwelt so long on the recital of the above, as I consider, very interesting case, I will endeavour to be more brief in what has to follow.

CASE II. In October 1827, I saw a gentleman named Daniels, affected much in the same way as Allen was. He had ulcers on the palpebral conjunctiva and tarsal or ciliary margin; also an enlargement of the left testis, or what has been called syphilitic arceole. Under the use of decoct. sarzæ and liquor arsenicalis, he soon improved, and in about two months was almost well, the sores being all healed, except one on the left arm, now also healing. The testis also was much reduced in size, under the application of ol. palmæ camphor. I saw him occasionally for a while; and on April 5th, 1828, I found he had been well for some time. I should add, that he had been under good medical advice for some time before I saw him.

CASE III. September 1841. I attended a Mrs. B., affected with an eruption of rupia and the phagedænic form of secondary syphilis. The throat was ulcerated, and there was ulceration of the palpebral

conjunctiva near the ciliary margin. There was a large prominent crust in the hairy scalp, near the forehead; and a smaller one behind it. There was an ulcer on one thigh, succeeded by a few others on the foot. She had a good deal of pain, with some swelling and tenderness of the knees.

She was soon relieved by the use of anodynes and the iodide of potassium. The throat healed over very soon; and also the ulcer on the thigh, which was dressed with resin cerate and a small addition of red precipitate. The ulceration of her palpebræ continued for some time; and the crusts on the head were very slow in falling off and healing, the larger ones especially.

CASE IV. Ann Barlow, aged 23, married about fourteen months, came under my care as an out-patient of the Manchester Eye Hospital October 28th, 1847. The ciliary margin of the superior palpebra of the right eye was ulcerated away, except a small portion towards the external canthus. There was also an ulcerated state in the middle portion of the ciliary margin of the lower palpebra, which was more especially covered with a puriform fluid. The globe itself was unaffected, only it had been a little red occasionally. There was an enlarged gland, rather sore when touched, in front of the right ear; and a similar one just below the angle of the inferior maxilla on the right side. She complained of much pain, of a burning, throbbing, and lancinating kind, in the palpebræ and surrounding parts. That side of her face was hotter and redder generally than the other. About fourteen weeks previously, a small ulcer appeared under the upper eyelid. Her medical attendant at Ashton-under-Lyne applied to it stimulants and escharotics; but the ulceration extended to the tarsal margin, and had extended during the last fortnight. Pulse 96; tongue pretty clean; bowels confined; appetite indifferent; she complained of headache; the catamenia had not appeared since her eye was affected; and she thought she might be pregnant. She had had one child born at seven months—on May 3rd. It died of convulsions, when five weeks old. It had no particular eruption on the skin. About seven months after marriage, she became affected with sore places about the pudenda; and, some time before that, she had much vaginal soreness. Some months afterwards, her throat became sore and ulcerated; it was about two months in healing. Afterwards, her eye became affected; and, within the last fortnight, red hard spots had appeared on her legs; they were very sore to the touch, and apparently intermediate between nodes and erythema nodosum. There were several of them on the right leg, and a few on the left; they were not all on the periosteum. There were about three also on the left thigh, quite cutaneous. She could ascribe no cause for the complaint, except infection from her husband, who appeared to have had syphilis. Previously to her marriage, she was very healthy.

A colleague of mine, who accidentally saw the case, was, at first view of the palpebræ, impressed with the idea that it was a malignant and intractable affection; but, judging from its history and my former experience, I was inclined to entertain a more favourable opinion. I prescribed ten grains of blue pill three times a day; and with each dose two table-spoonfuls of an iodide of potassium mixture, and zinc ointment to the tarsi.

℞ Potass. iodid. ℥ij; syrup. pap. f. ʒiv; aquæ ad f. ʒxij.

Nov. 1st. The ulceration of the palpebræ looked cleaner, more kindly, and was attended with less pain.

Dec. 1st. The ulcerated parts were now nearly healed, the improvement having progressed regularly

since last report. The tarsal margins were again nearly even, being only slightly indented in one or two points. She had continued her medicines regularly. Sulphate of copper had been occasionally applied to the ciliary margin.

Jan. 10th, 1848. She continued pretty well, and scarcely any difference was observable in the two eyes.

September. She called again to express her thanks, and to show that her eyes remained well.

CASE V. July 29th, 1840. Jane Beresford, aged 21, married, came under my care as an out-patient of the Manchester Eye Hospital. She said that, about twelve months since, she became infected with syphilis by her husband. After suffering from secondary symptoms, in a few weeks she became affected with sore-throat, followed by ulcerating blotches on her legs and back, not more than two or three on the former, and one or two on the latter, all now nearly healed. Latterly the palpebræ had become affected, presenting a reddish swollen appearance, along with some ulceration of the ciliary margin, extending a little inwards upon the conjunctiva. I prescribed for her the same treatment as mentioned in the preceding case.

Aug. 3rd. The palpebræ were still reddish, and a little swollen; but the ulceration was already almost healed, and her general health was improving.

Nov. 12th. She had been for some time pretty well, and discontinued her medicines soon after last report.

CASE VI. On December 30th, 1863, I was consulted by Mr. N., a middle-aged man, unmarried, on account of an affection of his eyes and throat, which had been coming on for a week or more. The ciliary margins appeared red and somewhat swollen; and, on evertng the superior palpebræ, two small ulcers were visible on one of them, and one only on the other. Each ulcer was a little excavated, presenting a yellowish base, and was about the size of a split pea. They were all on the palpebral conjunctiva, quite within the ciliary margin, and, therefore, not observable until the palpebræ were everted. On examining the throat, a rather large yellowish ulcer was seen on the left tonsil. I prescribed him the same medicines as in the preceding cases, and a lotion for his eyes.

Jan. 3rd, 1864. The ulcers on the palpebral conjunctiva and left tonsil had lost their yellowish coating, and seemed healing.

Jan. 9th. The ulcers were now scarcely visible either on the palpebræ or tonsil. The medicines were continued.

Jan. 15th. The ulcers were now healed, and his general health was improved. He had, however, still some ulcers on his legs—a frequent, if not general, concomitant of this form of syphilis; the ulceration being often of a sloughy, phagedenic, or serpiginous character, at least in one period of its progress.

CASE VII. October 29th, 1864. I was consulted by a Mr. B., aged about 30, married, residing until recently at New York. He had an ulcer occupying the tarsal margin of the left superior palpebra, and extending somewhat within the conjunctival surface. The surrounding textures appeared reddish and thickened. He first noticed the affection about three weeks ago, and it had gradually become a little worse. He had not hitherto used any particular treatment for it. About eighteen months since, he became affected with a cutaneous eruption in large spots (ecthyma?) on his legs and shoulders, and also with ulcerated sore-throat; but these were now all healed, leaving rather large cicatrices on the skin. He said that he had gonorrhœa about the commencement of

his complaint, but was not certain as to the existence of primary sores. I prescribed for him nearly the same medicines as in the preceding cases; the blue pill being united with an equal quantity of extract of conium and mixture of iodide of potassium. The affected lid to be brushed occasionally with tepid water, and anointed afterwards with the milder mercurial ointment.

Nov. 2nd. The ulceration of the ciliary margin and adjoining palpebral conjunctiva, as well as the accompanying redness and swelling, were diminished. The cicatrices on his legs, etc., varied in size from that of a sixpence to about that of a shilling.

Nov. 7th. The external ulceration of the tarsus was now healed; that of the conjunctiva internally was contracting, and presented a healthy granulating surface. The swelling and redness of the margin had disappeared.

Nov. 19th. The ulceration was quite healed, leaving a slight, scarcely perceptible depression in the site of the lately ulcerated ciliary margin; and the cilia corresponding to that part had quite disappeared.

Reviews and Notices.

REPORT ON THE CHEAP WINES FROM FRANCE, ITALY, AUSTRIA, GREECE, AND HUNGARY, ETC.
By ROBERT DRUITT, M.R.C.P., etc. Pp. 179.
London: 1865.

THE writer advocates the largely increased use of wine in diet and in medicine, and the use of greater variety. His is not a formal treatise on wine; but he takes the various cheap wines actually on sale in London at the present moment, and describes their qualities and uses. First, he discusses the difference between pure wine and fortified wine, observing that the English differ from every other civilised people on the face of the earth by their predilection for wine which has been dosed with about 20 per cent. of proof spirit. He shows that common spirit is more or less contaminated with fusel oil and other irritating substances, and is made out of the cheapest and commonest grain; and that this common spirit is largely exported to Portugal, and returns in the shape of port wine! He shows that pure wine, of natural strength and unfortified, has about 20 per cent. of natural spirit, derived from the fermentation of its saccharine element. He teaches us how to judge of wine, laying especial stress on the *body* of wine—*i. e.*, the totality of its sapid and aromatic ingredients, as contradistinguished from mere alcoholic strength. A mixture of spirit and water, he says, however strong, has no body. The question of acidity is also treated of, and a table is given with new determinations of the acidity of twenty-four kinds of wine. The headaches, heartburn, gout, etc., which follow the use of wine, he attributes to the wine being imperfectly fermented, or to the admixture with it of ardent spirits; and, let the wine only be pure, and there is no fear in drinking of it plentifully. Taking half-a-crown per bottle as a definition of cheapness, he gives a description of more than a hundred samples of cheap wine of all sorts which he has purchased and drank in London within the last two or three years; beginning with the Bordeaux and Burgundy; then taking the less known Greek, Hungarian, Austrian, and Italian

wines, of which he details the names, prices, taste, alcoholic strength, etc. Amongst the Hungarian and Austrian, he describes *all*, whether cheap or dear. There are also remarks on cider, mead, champagne and sparkling wines, and on cheap port and sherry, etc. The whole is interspersed with constant eulogies of that mode of philosophising which the writer calls "empirical", and which consists in arguing from the results of experience, and not from *a priori* considerations. Some space is devoted to an examination of hypotheses on which certain wines have been recommended by well known chemists and physicians, as, for example, Liebig. He and some of his disciples have asserted that good wine is "rich in phosphorus"; and have asserted of some wines, that they are good because rich in phosphorus, which is a very different thing. Our readers must often have noticed a wine advertisement in which the words "NO LIFE WITHOUT PHOSPHORUS" appeared in staring letters. It seems to give the writer a peculiar satisfaction to tear these hypotheses to rags and tatters, and to deride all systems of medicine and diet which do not rest upon experience.

The subject is naturally an attractive one even to teetotallers, and our author has certainly treated it in a practical and attractive manner. The British consumer of wine will derive both pleasure and profit from its perusal; but that he will be seduced from his strong and old-fashioned glass of port and sherry to the lighter draughts of Rhenish and Austrian, etc., produce, we will not venture to prophesy. Nevertheless, the author deserves our thanks for throwing his stone at the system of brandying natural wines and poisoning them with bad spirits.

A MANUAL OF THE DOMESTIC PRACTICE OF MEDICINE. By W. B. KESTEVEN, F.R.C.S. Pp. 339. London: 1865.

"It is not," says the author, "the intention of this Manual to supersede the office of the professional attendant." But many persons are themselves obliged to practise medicine, because they cannot procure the benefits of medical skill; and it is for the benefit of such that this book is written. Mr. KESTEVEN says that he has reason to know that the first edition of his Manual has been of service both at home and in the colonies. We have no doubt it has been so; but then, unfortunately, books of this kind are apt to be a source of error to the well-intentioned. A few distinct practical rules, comprehensible to ordinary non-professional understandings, are no doubt very serviceable to all persons, as well to those who can as to those who cannot obtain professional assistance; but works which enter too minutely into the subject are likely to be the source of mischief in the hands of the good-natured busybodies who generally undertake the duties of doctor in village and outlying districts, where doctors' aid is not readily procured. How, for example, can my Lady Bountiful, even with the help of this manual, make a diagnosis of "Brain, Inflammation of; Acute Water on the Brain; Acute Hydrocephalus"? Is it safe to tell that good lady that, in cases of this kind, she must give "an adult ten grains of calomel" and a senna purge; and, after action of the bowels, "calomel in doses of two grains every four or six hours" until the gums become inflamed; and also to tell her that, "when this

disease occurs in infants or children, the same line of treatment must be adopted, but the doses very much reduced"? The example we here give illustrates what seems to us the error to be avoided in books of this nature. They attempt too much. Those to whom they are addressed will, we may be very sure, think themselves equal to the occasion of any sickness described in it, and will operate accordingly; and no doubt, therefore, erroneously and very much to the injury of the patient. Works, therefore, on domestic medicine should, in our opinion, contain only matter of the most elementary character. To attempt therein a description of symptoms and the treatment of all diseases is, we fear, infallibly to lead the public into error, and into the doing of mischief either to themselves or to others.

ON THE METHOD OF THE STUDY OF MIND; an Introductory Chapter to a Physiology and Pathology of the Mind. By H. MAUDSLEY, M.D. London: 1865.

Dr. MAUDSLEY is a thoughtful writer, and has well studied the special subject of which he treats; and has, therefore, a good right to unfold his views on this very difficult subject.

THE STUDY OF SCIENCE, AND ITS UNDUE NEGLECT AS A BRANCH OF EDUCATION. Delivered (in part) as a Lecture at the Royal Institution of South Wales. By GEORGE PADLEY, M.D., Physician to the Swansea Infirmary. Pamphlet. Swansea: 1865.

THIS is a very sensible lecture, showing in well set terms the advantages of scientific studies as an ordinary part of education.

Progress of Medical Science.

MEDICINE.

POISONING BY ATROPIA: RECOVERY. Emilie M., aged 25, had for some time been using, by direction of an ophthalmic surgeon (Dr Förster of Breslau), an application of atropia to the eye. On March 6th, she procured from an apothecary a bottle of the preparation, containing one grain of sulphate of atropia in two drachms of water; and, at about half-past one o'clock on the same day, having had a quarrel with her mother, she drank the whole—at least, the bottle was found by the mother to be empty. Soon after taking the poison, she asked for milk, of which she drank nearly a pint; and, in half an hour, she had entirely lost consciousness and had occasional twitches. At three o'clock Dr. Körner saw her. She was lying in bed on the left side, entirely unconscious and incapable of being aroused by loud calling or by pinching the most sensitive parts of the skin. At intervals of two or three minutes there were convulsive movements, of short duration, in the face and limbs, the arms being moved forward on the chest. The skin was warm everywhere; the face was undoubtedly red; the eyes were closed. Both pupils were so much dilated that the iris could not be distinguished, and were quite insensible to light. The pulse was 130, very small, and compressible; the breathing was 16-18, stertorous. A solution of four grains of sulphate of copper in four ounces of water was ordered to be given in half-ounce doses every ten

minutes as an emetic. The first dose was administered with some difficulty, on account of the firm closure of the teeth. It was followed in five minutes by violent and copious vomiting of a greenish white milky fluid, mixed with much granular matter. Ice was applied to the head, and an enema of cold water and vinegar was given; this produced a motion in a quarter of an hour. Strong coffee was also given in teaspoonful doses. At a quarter before five, Dr. Cohn, the assistant of Dr. Förster (who had been sent for), saw the patient. She now lay with her face downwards, and it was with great difficulty that several persons could make her lie on her back. Consciousness and sensation were still entirely lost; the convulsions continued; no delirium was observed. The pulse was 140, very small. After she had taken five doses of the emetic mixture, she again vomited, the ejected matter being similar in quantity and character to that already mentioned. At five minutes before 5 p.m., half a grain of acetate of morphia in water was injected about half an inch above the exit of the right supraorbital nerve. In five minutes the pulse had sunk to 100; the countenance began to assume a lively red colour, and to become very hot; and the extremities were cold. At ten minutes past five, the patient was more easily kept lying on her back than before. The pulse was 120, but somewhat fuller; the respirations 15, still laboured, but not more stertorous. The convulsive movements continued; and there was a peculiar perpetual vibration of nearly all the muscular fibres, which could be especially felt in the masseter and pectoral muscles. The face was very warm; the hands cold. On being loudly called to, the patient shrank and opened her eyes, but was quite unconscious; she felt sharp pinching slightly. She had much difficulty in swallowing the coffee which was put by spoonfuls into her mouth. The left pupil seemed already somewhat smaller than the right. A little more than eight ounces of urine was drawn off by a catheter and retained for examination; and about the same quantity escaped into the bed. In addition to the ice to the head and the coffee, carbonate of ammonia was now ordered to be given every hour in ten grain doses. The hands were well wrapped in cloths wrung out of hot vinegar. At a quarter past six the patient for the first time answered a question. The answer was rational; but when she attempted to speak spontaneously, her speech was unconnected. At half-past six she was able to recognise the persons around her. She now talked much, and had rapidly alternating paroxysms of laughter and crying. At ten minutes before seven, a small piece of Calabar bean paper was laid on the lower conjunctival sac of the right eye. The pulse was 120; the breathing quiet and normal; the convulsions recurred less frequently. The medicines were continued. At 9 o'clock p.m., the patient was perfectly conscious, gave correct answers to questions, and complained only of weight in the head and difficulty in swallowing. Convulsive twitchings still occurred, but was very slight. The pupil of the right eye was decidedly wider than that of the left. The patient slept tolerably well through the night, and was out of bed at nine the next morning. She felt cheerful, but had some sensation of weight in the head and trouble in swallowing. Slight twitchings occasionally occurred in the feet, rendering her gait unsteady. The pulse was 60; the right pupil was $3\frac{1}{2}$, the left $2\frac{1}{2}$ lines in diameter; the pulse 60. The patient now confessed to having drank the entire bottle of atropia solution. At 7 p.m., the pulse was 80; her condition in other respects was the same. Three days after she had taken the poison, she still complained of difficulty in swallowing; the convulsive twitchings had entirely ceased; the head was free;

the pulse 80; the right pupil 3, and the left 2 lines in diameter. She was now convalescent. The urine was yellow, of specific gravity 1008, and free from albumen and sugar. A small quantity was concentrated by evaporation, and a few drops placed in the right eyes of three rabbits, with the effect, in each case, of producing a remarkable enlargement of the right pupil. (*Berliner Klin. Wochenschr.*, 17 April, 1865.)

URÆMIC CONVULSIONS. Dr. D. R. Haldane lays down and supports the following propositions. 1. In the present state of our knowledge, we seem justified in believing that the retention of urea is the chief cause of uræmic convulsions; though the effect of this agent is probably aided by individual peculiarities, and by deficient nutrition and consequent irritability of the brain, the result of the hydræmic condition of the blood. 2. It seems probable that the mass of the blood may be increased when deficiency of the urine is not compensated for by augmentation of other secretions, or by the occurrence of dropsy, and that this condition predisposes to apoplectic symptoms. 3. In cases where symptoms of cerebral congestion are present, especially where well marked contraction of the pupil exists, bloodletting is likely to do good. 4. In cases where symptoms of cerebral congestion are absent or all masked, and where dilatation of the pupil exists, bloodletting is likely to be injurious. 5. Chloroform is valuable as a palliative, especially in cases of puerperal convulsions; but when symptoms of cerebral congestion are present, it should not alone be depended on. (*Edinburgh Medical Journal*, April 1865.)

THE THERAPEUTICAL USES OF OX-GALL. Professor Wolff wishes to direct the attention of the medical public to a renewed trial of ox-gall, so that it may again effect the purposes for which it was formerly recommended. The ox-gall acts as a tonic, laxative, and nervine. As a tonic it is especially useful in dyspeptic cases dependent on atony of the gastro-intestinal canal; as a laxative when a powerful stimulation of the intestine is at the same time required, and in cases of deficient and morbid secretion of bile with attendant constipation. In such cases ox-gall is more useful than any other medicine recommended for the same conditions, and a patient who was treated by Dr. Wolff for symptoms of cirrhosis of the liver, jaundiced skin, obstinate constipation, and increasing emaciation, was completely cured by the use of this agent. Dr. Wolff also found this remedy very beneficial in two cases of spasm of the stomach in an especially severe form. In order to produce a laxative effect he ordered a tablespoonful of a solution of from four to six drachms of inspissated ox-gall in six ounces of aromatic fluid, to be taken four times a day; but to produce a tonic effect smaller doses are sufficient. (*Brit. and For. Med.-Chir. Review*.)

SURGERY.

EXTENSIVE INJURY OF THE LEGS BY MACHINERY: AMPUTATION: RECOVERY. August W., aged 17, was admitted into the Charité Hospital at Berlin on March 14th, 1864. On the morning of that day, he had been injured by the iron work of a threshing machine. The patient was a very weakly youth, of small size and strength and weak in intellect. On his admission, there was found to be considerable deformity of the left knee. The tibia was broken close below the joint, and the lower fragment was displaced backwards and upwards; and an angular projection end-

ing in a sharp point could be felt behind the joint. When the leg was fully extended, this part formed a sharp projecting swelling, which disappeared when the joint was bent. Moderate but decided crepitation was perceived during these movements. The upper fragment of the bone formed a small projection anteriorly. The external malleolus and the lower end of the fibula were also broken on the left side; there was, however, no displacement of the fragments, but some crepitation and abnormal mobility. The joints of the knee and foot appeared to be uninjured. The right thigh was broken close above the knee. The upper fragment projected somewhat forwards; the lower, although very small, had undergone partial rotation on its axis, so that the internal condyle was directed somewhat forwards, and the external condyle backwards. There was distinct but slight crepitation, and slight abnormal mobility. It could not be ascertained whether there was a fracture between the condyles; the knee-joint was apparently unhurt. There were some contusions and slight bruises on the face and other parts. Chloroform having been given, the displacements of the left leg were reduced, and the limb was put up in a plaster of Paris bandage, over which a bladder of ice was applied. The right thigh was laid on a double inclined plane, and ice was applied to it also; and, after some days, a plaster of Paris bandage was used. The progress of the case was tedious, in spite of the greatest care; and it was only at the end of April that a tolerably good union of the fractured parts appeared to have taken place. At this time there set in painful swelling over the end of the fibula and external malleolus; this was in vain treated with antiphlogistics, and at last burst and discharged a thin pus. Examination with a probe detected separation and necrosis of the fibula. In May the joints of the left knee and foot became diseased; and, as the patient's constitution was thereby seriously affected, the left thigh was amputated at the lower third on May 30th, by the circular incision. On examination of the removed limb, the following appearances were found. 1. There was a removal of the epiphysis of the upper end of the tibia, and an attempt had been made at firm union. The upper fragment was dislocated forwards, so that the two fragments did not lie in apposition; the free parts presented some new formation of bone. There was no necrosis. 2. Both epiphyses of the fibula were displaced. The surfaces were tolerably smooth. The upper epiphysis was necrosed on the outer side, the lower one entirely. 3. The joint of the left foot was destroyed, and there was commencing suppurative in the knee-joint. The amputation wound healed slowly, but without any untoward symptoms. In the meantime, the fracture of the right thigh became united; the fragments, however, not having regained their normal position. The patient was discharged, able to use the limb well. (*Berliner Klin. Wochenschr.*, 10 May, 1865.)

DISLOCATION OF THE HIP-JOINT INTO THE SCIATIC NOTCH: REDUCTION AFTER FIVE WEEKS. On August 7th, 1864, Dr. Zimmer of Fulda was called by a woman to prescribe an embrocation for her brother. On inquiry, he found that, five weeks previously, the man had been thrown from a waggon of hay and had thereby dislocated the hip-joint. He was treated during four weeks by cold applications and embrocations; but, from the description given by the woman, Dr. Zimmer concluded that reduction had not been effected, although he had been under the care of two medical men. The next day, he saw the patient. The right foot was strongly inverted, the buttock turned to the right and outwards, and the thigh shortened by at least six centimètres. The patient

was entirely unable to raise the thigh. On examination, the head of the bone was found in the sciatic notch. On the 9th, Dr. Zimmer, with two assistants, attempted to reduce the limb. The patient was placed under the influence of chloroform, and the joint was moved in various directions as it had become nearly fixed. An assistant then fixed the pelvis with his hands; another knelt at the side of the dislocated bone with his right arm in the popliteal space and his left embracing the limb at the same part and making extension. This manoeuvre was unsuccessful. Dr. Zimmer then bent the dislocated limb to a right angle and performed adduction, so that the knee approached the hip of the other side; this was attended with a crackling sound, as if some bands had been torn through. The dislocated limb was then rolled outwards, and at the same time an assistant produced strong extension; wherein the head of the bone returned audibly into its normal position. The foot and buttock now resumed their proper direction. The patient's recovery was rapid; and he was well able to walk a long distance, with some support, on August 29th. (*Berliner Klin. Wochenschr.*, 6 May, 1865.)

MIDWIFERY AND DISEASES OF WOMEN.

LIGATURE OF THE PEDICLE IN OVARIOTOMY. A discussion took place lately at the Pathological Society, relative to the use of silver wire as a ligature for the pedicle in ovarian operations. The silver wire is left on the pedicle, as recommended by Dr. Marion Sims, and excellent results follow. The ligature buries itself in the pedicle, but produces temporary pressure sufficient to arrest the hemorrhage. When, however, it has buried itself in the pedicle, the pressure is diminished, and so enough vitality left in the stump to enable it to adhere to the peritoneal surface, and to prevent its sloughing. Dr. Marion Sims had observed, when operating with silver wire on a nœvus on the face, that the wire, which at first completely strangled the nœvus, had on the next day buried itself in the skin which had healed over it; and that it no longer completely obstructed the circulation. He therefore recommended its use in the removal of ovarian tumours. It was stated that the silk suture was also used in a similar way by Dr. Tyler Smith, who returned and left it in the abdomen attached to the pedicle; and had found no bad consequences result.

PUERPERAL FEVER. Dr. D. Miller, of Chicago, as chairman of the Committee on Puerperal Fever, has presented a report upon this affection. With the most modern pathologists it is considered due to a new element not found in ordinary inflammation, which renders its nature essentially different from peritonitis, phlebitis, metritis, etc. The new element, we are led to believe, is a poison in the blood, producing a septic influence there—and through this medium producing changes sometimes in the tissues of important organs. That the disease is truly zymotic. Its history observes the laws of all poisons. 1. It is a uniform disease; the description given of it an hundred years ago, describes the disease of to-day equally well. It selects a tissue for its seat, viz., the serous membranes and tissues analogous to them. 3. The definite action is in the blood; the quantity of fibrine is increased, its quality is deteriorated. 4. The action of the poison is modified by the quantity introduced into the circulation. When it is in excess the patient may die suddenly without leaving any local manifestations of its presence. When the poisoning is in less quantity, its course is less rapid,

and is followed by local changes. Without attempting to trace this poison to its source, or detail its mode of propagation, he concludes that: 1. It may originate within the system, from the decomposition of organic matter; 2. It may be introduced from without, by exposure to diseases characterised by ichoræmia; or, 3. It may be communicated by the attendant, who is the vehicle of transportation from a distant case. Dr. Miller arranges the treatment under three propositions; 1. Neutralise the *materies morbi* in the system, in the uterus, and in the vagina. 2. Eliminate the disintegrating and effete materials from the system. 3. Support the vital forces of the system. He believes the first can be fulfilled by *chlorine* and *bromine* as injections into the vagina and uterus; while the second indication is carried out by such articles as are known to arrest the septic influence of the poison already circulating with the blood; such as the mineral acids, chlorine salts, the bromides and sulphides. The third object is accomplished in the usual manner by nutritious food and judicious use of alcoholic preparations. (*Phil. Med. Journal.*)

ANATOMY, PHYSIOLOGY, & PATHOLOGY.

CYSTICERCUS IN THE CAPSULE OF THE LENS. At the meeting of the Berlin Medical Society on February 8th, Dr. Von Gräfe mentioned a case in which, on an operation being performed for cataract, a cysticercus cellulose was found within the capsule of the lens. This is the first instance in which the cysticercus has been found in this situation. (*Berliner Med. Wochen.*, 27 März, 1865.)

THE PRÆPATELLAR BURSE. Dr. S. H. Scheiber of Bukarest has published the results of examinations made by himself and Dr. Quinquerez on one hundred bodies, with regard to the presence and anatomical relations of the synovial bursa in front of the patella. He finds the following results. 1. The bursa lying in front of the patella, between this bone and the integument of the knee, are either (a) situated superficially or subcutaneously between the skin and the fascia lata; (b) between the fascia lata and the tendon of the extensor quadriceps; or (c) between the last named tendon and the patella. 2. Of these three bursæ, one, two, or all three may be present in the same individual. 3. They are to be found at all ages, from 13 to 82. 4. In 100 subjects examined, 22 presented no præpatellar bursa; in 15 there was a bursa on each side only; in 63 on both sides. 5. In 10 cases all three kinds were met with; but one subject only had the three bursæ on each side. 6. The proportion of their occurrence on the right and left sides is nearly the same. 7. The presence or absence of the præpatellar bursa is of nearly the same frequency in both sexes. 8. These bursæ were mostly found in men aged from 40 to 50, and in women from 20 to 30. 9. In 13 cases there was a communication between the two bursæ; those so connected being always the superficial and middle sacs. (*Wiener Medizin. Wochenschr.*, 15 May, 1865.)

THE TURKISH BATH. We learn that the promoter of the Turkish bath at Geneva, Mr. David Urquhart, formerly a member of the English parliament, after having passed the winter at Geneva, has quitted us to establish himself on Mount Prarion (near St. Gervais). Mr. Urquhart is building, 6,000 feet above the level of the sea, a Turkish bath, to try its efficacy for the cure of cretinism. (*Journal de Genève*, May 16th, 1865.)

British Medical Journal.

SATURDAY, JUNE 3RD, 1865.

THE PUBLIC ESTIMATE OF MEDICAL SCIENCE.

ALTHOUGH the medical profession was but sparingly included in the hospitality lately afforded by the Lord Mayor to the notables of the scientific world, and though no notice was taken of them in the programme, we cannot but congratulate our readers on the occasion.

A banquet given to the President and Council of the Royal Society, as the representatives of science, was a fitting compliment, paid at an appropriate time. It is the function of the Royal Society to gather in all contributions towards further discovery of the laws of Nature, whether communicated by professional men or by amateur philosophers, it sifts these contributions, and judges their merits; and it is becoming, as it ought to be, more and more the practical authority of the State for the due application of the knowledge thus accredited. As an instance of prudent deference to the best authority, we may observe that the Government, awakened to the difficulties and perils attending the large introduction of iron into shipbuilding, tardily convinced that many losses of property and life are to be attributed to a consequent deviation of the compass, and finding also that, in consequence of the large amount of iron, Professor Barlow's system of correction has become inapplicable, have referred to the Royal Society, and that Society has furnished valuable assistance. And when it is remembered that the safety, not only of the navy, but of the mercantile marine, is compromised by this deviation, as well as probably by other causes which come within the province of scientific investigation, we must all acknowledge the importance of the body of learned men who form the recognised organ of philosophical discovery for the benefit of the nation.

We must, however, contend that there is another large class of philosophers who are equally labouring for the public good—the medical profession; and it is not without a certain sense of injustice that we observe so little account to have been taken of them in the recent honour paid to science.

The City functionaries are probably not aware of the intimate connexion between the Royal Society and the Royal College of Physicians at the first formation of the former. The nucleus of the Royal Society was formed in Gresham College, in the days when the Royal College of Physicians was a City corporation, under a separate Royal Charter; and a large proportion of those who attended the meetings

whence the Society emanated were the leading physicians of the day.

It would be superfluous to contend that medical philosophy has the widest bearing on the good of society, and that it includes all branches of natural science; the fact, therefore, that it is forgotten, suggests some significant reflections. It almost seems as if the scientific pursuits of medical men and the profession itself are declining in general estimation; and, should this be true, does it not become us to regard it as a call to set our house in order, and to inquire whence is the falling off in its condition?

Can the fault lie with the heads of the profession? Are they making no advance in medical and natural philosophy; forgetting true science in the race for practice; seeking a reputation which bears no fruit but the emolument—a mere fleeting popularity, which leaves no traces of original thought, and bequeaths no fund of discoveries for the benefit of succeeding generations? And further, should there really be this debasement in the aims of men whose predecessors strove to throw new light upon disease, laboured with noble philanthropy to afford relief, and pushed their discoveries into every branch of natural science; as Harvey, revealing the circulation of the blood; Baillie, demonstrating morbid change; and Young, developing the undulatory theory of light. How has this been brought about? Is it to be looked for partly in the democratic spirit which has invaded all professions, discouraging preliminary mental training, equalising education in all the branches, which tends not so much to raise the useful workers to higher efficiency, as to obliterate the class from which deep study, new views, keen apt opinions were to be looked for? or must we seek the deteriorating influence without the pale? Is it to be found in that materialistic tendency which affords no encouragement but to professions which minister to the accumulation of wealth and the invention of new luxuries? or is it in that waywardness and love of quackeries and silly novelties—that want of faith in knowledge as opposed to ignorance—which pervade the general public, which have crushed out too much of the energy which once made our profession famous?

POOR-LAW MEDICAL INSPECTORS.

A REPORT of the proceedings of a deputation which waited on Mr. Villiers at the Poor-law Offices on the 29th ultimo, is given at another page. The main object of the deputation was to ask the Poor-law Board to take into consideration the propriety of appointing medical inspectors under the Poor-law, for the purpose of visiting, investigating, and reporting upon the treatment of sick paupers. The deputation was very courteously received by Mr.

Villiers; but not much hope was held out by him for the appointing of such Commissioners; although the necessity for their appointment was clearly enough made out, and must be, indeed, apparent to every medical man.

Mr. Villiers said, the thing most needed at present was that greater powers should be given to the Poor-law Board, whose best efforts were often paralysed through the effectual opposition of Boards of Guardians. At present, the Poor-law Board issue their orders and recommendations to the Boards of Guardians; but, in many instances, they have no power at all to enforce the carrying out of those orders. Boards of Guardians, in fact, constantly set them at defiance. The Poor-law Board have even tried to enforce their orders through courts of law; but even then they have also failed.

Now, it seems to us, that the answer to Mr. Villiers should be this: Nothing more plainly shows the necessity for the appointment of Medical Poor-law Inspectors than this very statement. The orders set at nought by the Boards of Guardians, in the main, are orders affecting sanitary arrangements. Now, it is clear that, if the Poor-law Board could issue reports, on the high authority of Medical Inspectors, showing the absolute necessity for the carrying out of the orders issued by the Board, Parliament would at once give the Board the powers necessary for the purpose. At present, the Poor-law Board have not any such authoritative documents to lay before Parliament, and Parliament, therefore, does not give them the powers required.

The only objection stated by Mr. Villiers against the appointment of Medical Inspectors was that the country would object to the expense. But if this is all that can be urged against the proposal, there is evidently nothing to be said against it. It is not necessary for us to argue to medical men, that no class of persons can be so well fitted as medical men to superintend the hospitals, etc., of the sick paupers of the country. Why, have we not again and again had the proofs of it demonstrated to us—first, in facts which have shown the disgraceful treatment of sick paupers; and secondly, in the other fact that when inquiries have been instituted into these disgraceful disclosures, the Poor-law Inspector is obliged to call in some non-official medical man to assist him? Who can doubt, if medical Inspectors were appointed, that their well experienced eyes would enable them, at this moment and in all parts of the country, to detect abuses in the treatment of the sick which have naturally escaped the eye of the non-medical Inspector? In Mr. Villiers's own statement, therefore, that Boards of Guardians defy the Poor-law Board, we find the very strongest argument in favour of the appointment of Poor-law Medical Inspectors. We sincerely trust that this question will not be allowed to drop. We verily believe

that such appointments would be the first step to the doing of some effectual justice to the sick; and would inevitably tend to the amelioration of the Poor-law medical officers' present cruel position.

Since the above lines were written, we read, to our surprise, in the *Times* of the 1st inst., that

"The President of the Poor-law Board has appointed Edward Smith, M.D., author of *Practical Dietary for Families, Schools, and Labouring Classes*, and also of a Report on the Dietary of Lancashire Operatives and Low-fed Populations, and other works affecting the health and well-being of the poor, as Inspector of Poor-law."

We most sincerely congratulate the President on his good sense in doing this plain act of justice. We trust the appointment is a permanent one. It can, however, only be regarded as an instalment of the proper thing; for it is manifest that one medical inspector is quite unequal to cope with the work which ought to be done.

SOME remarks lately made in this JOURNAL, respecting the uses and abuses of beef-tea as an article of diet in our hospitals, have, we hear, already found an echo in one of our large London hospitals. Our remarks have, in fact, led to an inquiry there into the cost and quantity of the beef used for the purpose of making beef-tea, and of its value as a nutriment. Some very striking facts have already been elicited. We believe it is true that the beef used for making beef-tea in the hospital referred to costs something over £1,400 *per annum*; that about 50,000 pounds of beef—*i.e.* about 1,000 pounds a week—are used in its manufacture; and that, in fact, the beef-tea of each patient costs about one-half of the whole sum expended on his diet. The *bouilli*—that is, the solid material from which the beef-tea is made—is, of course, all thrown away, or partially wasted. The fat is skimmed off, and probably also goes into the hog-tub; and the muscular fibre, which forms the great bulk of the meat, passes into the same receptacle. Thus, in fact, the very greatest portion of the meat is absolutely wasted. We leave our readers to decide how much solid matter there is contained in a pint of beef-tea. But small it must be; and assuredly it is all the representative of a pound of flesh which finds its way into the stomach of the patient. If physiologists tell us truly, the whole of the muscular fibre of meat is capable of being dissolved and absorbed in its passage through the digestive organs. Why, then, should the enormous bulk of muscular fibre—nutritive matter—left after the manufacture of beef-tea, be thrown away into the pig-bucket? If, for example, we suppose that a pint of beef-tea contains one ounce of solid materials derived from the sixteen ounces of meat from which it is extracted, then the fifteen ounces of flesh are thrown away; so that, of the

50,000 pounds of meat used at the hospital in question for making beef-tea, upwards of 45,000 pounds are thrown away. Besides this, all the fat is carefully removed from the meat, and carefully skimmed from the beef-tea, and, no doubt, in great part lost as an article of nutriment. Hence, it appears that each patient, who has a pint of beef-tea *per diem*, consumes $6\frac{1}{2}d.$ worth of meat; whilst the meat in his ordinary diet costs only $2\frac{1}{2}d.$ We sincerely hope that the attention of our hospital medical officers will be called to this question in hospital economics; for it is certain, when we consider the immense consumption of beef-tea throughout the country, that it is one of serious importance. Without at all touching the question of the value of beef-tea as an article of sick-diet, we may very reasonably affirm that the rejection of the meat from which the beef-tea is made is pure waste of highly nutritive flesh-forming matter. The rejected matter consists wholly of fibrous and albuminous tissues, every particle of which is capable of being dissolved and absorbed into the system. And especially ought attention to be called to this subject, at a time when meat has become an exceedingly expensive article of food.

SIR CHARLES LOCOCK has issued his address to the electors of the Isle of Wight. He offers himself as a moderate conservative candidate. We must express a hope that he will receive the earnest support of the medical profession in the island. His presence in the House would be a very great boon to the profession at large. Sir Charles Locock has always shown himself to be an earnest supporter of the best interests of the profession; and would, we are satisfied, gladly give his aid, were he in Parliament, to the promotion of its welfare. One of the greatest misfortunes to medicine is, as we have all so often lamented, that we have no proper spokesman in the House of Commons. Here there is assuredly an occasion for us to lay hold upon. Sir Charles Locock, by his high position, would be naturally regarded as an authoritative exponent of medicine in the House; and we may be very sure, from his well known business habits, that he would always be ready energetically to support our interests there.

CAPTAIN GROSVENOR, one of the candidates for the representation of Westminster in Parliament, and Mr. Hughes, a candidate for Lambeth, are both of them, we believe, staunch homœopaths. The latter gentleman, as our readers may remember, lately held a prominent position as defender of that creed at the annual dinner of the Homœopathic Hospital. Our own idea is, that, independently of all professional antipathy to the spreaders of that fallacy, no man who believes in it can be possessed of that plain matter-of-fact sense and judgment which should be required of a legislator. A man who is a quack in

one thing is, in our opinion, likely to be a quack in all things; that is, he is possessed of an intelligence which takes contracted views of things. He may be good and clever, and even a genius; but he is wanting in bottom and soundness and common sense.

THE remarks made by the *Wiener Med. Woch.* to the effect that the Government at St. Petersburg would not allow the foreign physicians who visited that capital to study with their own eyes the epidemic then raging, seem confirmed by the silence of our own Board of Health. Dr. Whitley was, as our readers will remember, many weeks ago, despatched in hot haste to St. Petersburg; but nothing in the way of information upon the subject of his special visit there has as yet found its way, either directly or indirectly, into print. The Vienna journal says, that the foreign doctors have been received by the Russian doctors with open arms and extreme politeness; that they have been *fêted* and champagne'd; but have been carefully admitted only into those hospitals and localities where no epidemic fever existed. This might have been expected. Publicity is not the order of the day in Russia.

MR. SPENCER WELLS objects to the operation of incision of the mouth and neck of the womb, as performed by Dr. Marion Sims. In his opinion, the use of the speculum is neither necessary nor desirable in the performance of the operation. "The operation can be much better done with a proper instrument in a second or two by the touch alone, than it can by a complex process of speculum, assistant, hook, scissors, knife, and plugs, as advised by Dr. Sims." Further, he says that there is no necessity to do more than cut through the mucous membrane and the innermost layer of muscular fibres. Mr. Wells holds it "to be not only unnecessary, but dangerous and injurious, to cut into the thick middle layer of muscular fibres." Mr. Wells says he has seen two fatal cases of periuterine abscess after free incision in the practice of others. He is confident that very "free incisions are as unnecessary as they are dangerous."

Dr. Simas, of La Miséricorde at Lisbon, gives the following as the results of 216 cases of hereditary syphilis observed by him between January 1858 and February last. Of these, in 27 cases the disease appeared during the first month, in 49 cases during the second, in 56 cases during the third, in 30 cases during the fourth, in 14 cases during the fifth, in 16 during the sixth, in 7 during the seventh, in 2 during the eighth, in 7 during the ninth, in 4 during the eleventh, in 1 during the thirteenth, in 1 during the fourteenth, and in 2 during the eighteenth. These statistics show that the disease may appear at a much later date than is usually supposed.

INSPECTION OF WORKHOUSE HOSPITALS.

On Tuesday last, a deputation from the Workhouse Visiting Society had an interview with the Right Hon. C. P. Villiers, M.P., President of the Poor-law Board, on the subject of the constant inspection of workhouse hospitals by medical men. The deputation was introduced by the Earl of Devon; and was accompanied by C. Buxton, Esq., M.P., E. Warner, Esq., M.P., G. Lyall, Esq., M.P., A. Smith, Esq., M.P., Sir J. K. Shuttleworth, Bart., Dr. Watson, Dr. Burrows, Dr. Goodfellow, Dr. Sieveking, Dr. Markham, and Dr. Stallard.

The Earl of DEVON, whilst not committing himself to the particular recommendation of the deputation, thought that the question ought to be ventilated; and believed the Poor-law Board anxious to assist in any improvement which might be really necessary.

Mr. BUXTON, M.P., said that there could be no doubt that improvement in workhouse hospitals was urgently required. The deputation believed that the appointment of medical inspectors would secure for the sick poor proper attention, advice, medicines, and other comforts. The many evils of the present system would be removed by degrees; the nursing would improve; and all might be done at a moderate expense.

THE PRESIDENT OF THE POOR-LAW BOARD inquired as to the particular defects which, in the opinion of the Visiting Society, rendered necessary the appointment of medical commissioners.

Dr. STALLARD said that the following defects had been observed.

1. That, compared with other hospitals, the medical staff is insufficient and underpaid.
2. That the united service of advice and medicines is not calculated to secure the best of either that can be obtained.
3. That the medical officers are subject to no medical inspection or control, so that the public have no guarantee that the duties are well performed.
4. That the construction of workhouse hospitals is generally defective; the wards being small, ill-ventilated, over-crowded, and unprovided with the furniture and comforts supplied at other hospitals.
5. That the nursing is most inefficient, the paupers being morally and physically unfit for the duties too often imposed upon them.

The Society, therefore, urged the appointment of two physicians and one surgeon as additional commissioners, to organise and inspect the administration of workhouse hospitals, and to advise the Poor-law Board in all sanitary and medical questions.

Mr. LYALL, M.P., stated that a new infirmary had been built for the Reigate Union some years ago; that the plans had been approved of by the Poor-law Board; but, not having been submitted to medical inspection, they have been found inefficient in many respects. He thought that medical inspectors should be employed to supervise the construction of workhouse hospitals and the details of their management.

Dr. GOODFELLOW said that no one could be satisfied with the present state of the workhouse hospitals. The medical treatment of lunatics and criminals was far better than that of the poor. The qualification for the office of union surgeon was lower than that for the gaol or lunatic asylum; and the salaries were in many cases such as to prevent the best class of medical men holding the appointment. If the election of surgeon could not be taken out of

the hands of the Guardians, he would recommend payment *pro rata*, according to a scale to be fixed upon by the Poor-law Board.

Mr. WARNER, M.P., stated that it was clear that there were many subjects upon which medical inspectors could alone decide; as, for instance, the dietary of the sick, which ought to be regulated by medical authority. They were alone gauges as to the adequacy of the hospital accommodation, the character of the nursing, the quality of the drugs supplied, and many other matters equally important. In his opinion, the inspection must be persistent and at short intervals.

Dr. SIEVEKING stated that, at least in one particular, the Poor-law Board had signally failed; it was in the matter of nursing. Guardians had not regarded a circular of the Board issued some years ago. He believed that the Board would be greatly strengthened by the appointment of eminent medical men as additional commissioners. They would act as *amici curiæ*, and assist in carrying out the improvements required. The persons so appointed must not be expected to work in a desultory manner; but must give their whole time and energies to the duty before them. A mere knowledge of medicine or surgery would not suffice, without special acquaintance with the workhouse hospitals.

Mr. VILLIERS observed that the Poor-law Board had undoubtedly effected great improvements, and he was anxious to receive any new suggestions. He agreed as to the propriety of at least occasional inspections by physicians of eminence; but the main difficulty he had to contend with was the existence of local acts, which enabled the guardians to resist the authority of the Poor-law Board. He hoped to bring in a Bill for remedying this defect; and he would give the question of medical inspection his serious attention.

The Earl of DEVON having thanked Mr. Villiers for his courtesy and attention, the deputation withdrew.

LAST HOURS OF ABRAHAM LINCOLN.

Mr. C. S. Taft, Acting Assistant-Surgeon, United States army, furnishes the following account of the progress of the case of President Lincoln, and of the *post mortem* examination.

While sitting in an orchestra chair at Ford's Theatre, on the 14th inst., about 10.30 P.M., I heard the sharp report of a pistol in the direction of the State box, and turning my head in that direction, saw a wild-looking man jump from the box to the stage, heard him shout "*Sic semper tyrannis*," as he brandished a glittering knife in his right hand for an instant, and dart across the stage from sight. A few moments of utterly indescribable confusion followed, amid which I heard a call for a surgeon. I leaped upon the stage, and was instantly lifted by a dozen hands up to the President's box, a distance of twelve feet from the stage.

When I entered the box, the President was lying upon the floor. The respiration was inaudible and scarcely perceptible, and he was totally insensible. Assistant-Surgeon Charles A. Leale, United States Volunteers, was in the box, and had caused the coat and vest to be cut off, in searching for the wound. The wound in the head was soon found, but at that time there was no oozing from it. The President was removed to a house opposite, and laid upon a bed in fifteen minutes from the time the shot was fired. The finger being used as a probe, the ball was found to have

passed beyond the reach of the finger into the brain. A teaspoonful of diluted brandy was swallowed with much difficulty; a half-teaspoonful administered ten minutes afterwards, was retained in the throat, without any effort being made to swallow it. The respiration now became laboured; pulse 44, feeble; eyes entirely closed; the left pupil much contracted, the right widely dilated; total insensibility to light in both.

Surgeon-General Barnes and K. Stone, M.D., the family physician, arrived. The left upper eyelid was swollen and dark from effused blood; this was observed a few minutes after his removal from the theatre. About thirty minutes after he was placed upon the bed, discoloration from effusion began in the internal canthus of the right eye, which became rapidly discoloured and swollen with great protrusion of the eye.

About 11.30 P.M., twitching of the facial muscles of the left side set in and continued some fifteen or twenty minutes, and the mouth was drawn slightly to the same side. Sinapisms over the entire anterior surface of the body were ordered, together with artificial heat to the extremities.

The wound began to ooze very soon after the patient was placed upon the bed, and continued to discharge blood and brain-tissue until 5.30 A.M., when it ceased entirely; the head, in the meantime, being supported in such a position as to facilitate the discharge.

Colonel Crane, surgeon, had charge of the head during a great part of the time. While the wound was discharging freely, the respiration was easy; but the moment the discharge was arrested from any cause, it became at once laboured. It was also remarkable to observe the great difference in the character of the pulse whenever the orifice of the wound was freed from coagulum, and discharged freely; thus relieving, in a measure, the compression. This fact will account for the fluctuations in the pulse.

About 2 A.M., an ordinary silver probe was introduced into the wound by the Surgeon-General. It met an obstruction about three inches from the external orifice, which was decided to be the plug of bone driven in from the skull and lodged in the track of the ball. The probe passed by this obstruction, but was too short to follow the track the whole length. A long Nélaton probe was then procured and passed into the track of the wound for a distance of two inches beyond the plug of bone, when the ball was distinctly felt; passing beyond this, the fragments of the orbital plate of the left orbit were felt. The ball made no mark upon the porcelain tip, and was afterwards found to be of exceedingly hard lead. No further attempt was made to explore the wound.

After the cessation of the bleeding from the wound, the respiration was stertorous up to the last breath, which was drawn at twenty-one minutes and fifty-five seconds past seven; the heart did not cease to beat until twenty-two minutes and ten seconds past seven. My hand was upon the heart, and my eye on the watch of the Surgeon-General, who was standing by my side, with his finger on the carotid.

The decubitus during the whole time was dorsal, and the position on the bed diagonal, the length of the bedstead not admitting of any other position.

The respiration during the last thirty minutes was characterised by occasional intermissions, no respiration being made for nearly a minute; but by a convulsive effort air would gain admission to the lungs, when regular, though stertorous, respiration would go on for some seconds, to be followed by another period of perfect repose.

At these times the death-like stillness and suspense

were thrilling. The cabinet ministers, and others surrounding the death-bed, watching, with suspended breath, the last feeble inspiration, and as the unbroken quiet would seem to prove that life had fled, turn their eyes to their watches; then as the struggling life within would force another fluttering respiration, heave deep sighs of relief, and fix their eyes once more upon the face of the dying chief.

The wonderful vitality exhibited by the late President, was one of the most interesting and remarkable circumstances connected with the case. Mr. Lincoln lived from 10.30 P.M., until 7.22 A.M.

About 1 P.M., spasmodic contractions of the muscles came on, causing pronation of the forearms; the pectoral muscles seemed to be fixed, the breath was held during the spasm, and a sudden and forcible expiration immediately succeeded it. At about the same time both pupils became wildly dilated, and remained so until death.

During the night Drs. Hall, May, Liebermann, and nearly all the leading men of the profession in the city, tendered their services.

Autopsy, Five Hours After Death. The calvaria was removed, the brain exposed, and sliced down to the track of the ball, which was plainly indicated by a line of coagulated blood, extending from the external wound in the occipital bone, obliquely across from the left to right through the brain to the anterior lobe of the cerebrum, immediately behind the right orbit. The surface of the right hemisphere was covered with coagulated blood. After removing the brain from the cranium, the ball dropped from its lodgment in the anterior lobe. A small piece of the ball, evidently cut off in its passage through the occipital bone, was previously taken out of the track of the ball, about four inches from the external wound. The hole made through the occipital bone was as cleanly cut as if done with a punch.

The point of entrance was one inch to the left of the longitudinal sinus, and opening into the lateral sinus. The ball was flattened, convex on both sides, and evidently moulded by hand in a Derringer pistol-mould, as indicated by the ridged surface left by the nippers in clipping off the neck.

The orbital plates of both orbits were the seats of comminuted fracture, the fragments being forced inward, and the dura mater covering them remaining uninjured. The double fracture was decided to have been caused by *contrecoup*. The plug of bone driven in from the occipital bone, was found in the track of the ball, about three inches from the external wound, proving the correctness of the opinion advanced by the Surgeon-General and Dr. Stone as to its nature, at the exploration of the wound before death.

The ball and fragments, together with the fragments of the orbital plates and plug from the occipital bone, were placed in the possession of Dr. Stone, the family physician, who marked and delivered them, pursuant to instructions, to the Secretary of State, who sealed them up with his private seal. The Nélaton probe used was also marked by me, and sealed up in like manner. (*Phil. Med. Reporter.*)

MEDICAL LOGIC. The nomadic tribes who inhabit the steppes of Russia are said to be completely exempt from pulmonary consumption. They also indulge in *Kumis*—an intoxicating liquid made by fermenting mare's milk. Here are two facts for a medical logician, Dr. Schnepf, who argues from them that *Kumis* is prophylactic against consumption. But mare's milk is not easy to get; the Doctor therefore contents himself with asses' milk—from which he prepares an intoxicating drink called *galazyme*, with which, he says, he treats most successfully all catarrhal affections and consumptions in general.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D.Cantab.

President-elect—S. J. JEAFFRESON, M.B.Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S.Ed., Professor of Clinical Surgery in the University of Edinburgh.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
SOUTH MIDLAND. [Annual.]	George Hotel, Northampton.	Wednesday, June 7, 2 P.M.
BIRMINGHAM AND MID- LAND COUNTIES. [Annual.]	Hen and Chickens Hotel, New Street, Birmingham.	Friday, June 10th, 3.30 P.M.
LANCASH. & CHESHIRE. [Annual.]	Royal Institution, Manchester.	Wednesday, June 21.
NORTHERN. [Annual.]	Library, Newcastle- upon-Tyne Infirmary.	Wed., June 23, 10.30 A.M.
METROPOL. COUNTIES. [Annual.]	Crystal Palace, Sydenham.	Tuesday, July 4th, 3 P.M.

SOUTH MIDLAND BRANCH.

THE annual meeting of the South Midland Branch will be held at the George Hotel, Northampton, on Wednesday, June 7th, at 2 P.M.; GEORGE ASHDOWN, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, as soon as possible; or not later than the 23rd instant, to Dr. Bryan, Northampton.

JOHN M. BRYAN, M.D. } *Hon. Secs.*
G. P. GOLDSMITH. }

Northampton, May 15th, 1865.

LANCASHIRE AND CHESHIRE BRANCH.

THE Annual Meeting of the Lancashire and Cheshire Branch will be held on Wednesday, June 21st, in the Royal Institution, Mosley Street, Manchester; THOS. TURNER, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Honorary Secretary, without delay.

WM. ROBERTS, M.D., *Hon. Secretary*.

69, Mosley Street, Manchester.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 25th, at 10.30 A.M.; D. B. WHITE, M.D., President.

The Council of Management hope that gentlemen will prepare papers and cases, and forward the titles of the same to Dr. Philipson not later than June 17th. Dinner at 6 P.M.

G. H. PHILIPSON, M.B., *Hon. Secretary*.

Reports of Societies.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 20TH, 1865.

J. C. LANGMORE, M.B., President, in the Chair.

Medullary Cancer. Dr. ROYSTON exhibited a specimen of medullary cancer of the upper part of the right femur. The patient was a widow, aged 48 years, who had ricked her thigh whilst walking in the park in July 1862. Besides the disease in the right femur, there was a corresponding cancerous affection in the last lumbar vertebrae and in the sacrum. A small scirrhus tumour had existed in the left breast for the last five or six years. After death, both thigh-bones were found to be fractured at the junction of the upper and middle thirds. The left thigh-bone had been broken in moving the body after death.

Mr. SEDGWICK remarked that there had been some difference of opinion respecting the diagnosis of the disease in this case. He had seen the patient several times during life; and as there was family history of cancer, a sister having previously died of scirrhus of the breast, and as the patient herself also had a scirrhus tumour in her left breast, he had come to the conclusion that she was suffering from secondary cancer in the femur. He was glad to find that the examination after death had confirmed his diagnosis of the case.

Dr. BOYD MUSHET referred to a case of cancer which had come under his observation, in which fracture of both thigh-bones had occurred during life.

The Etiology of Pulmonary Apoplexy. By W. BOYD MUSHET, M.B. The author had hitherto associated the causation of pulmonary apoplexy with an impaired condition of the valvular apparatus on the left side of the heart. Whilst, however, he was engaged in arranging his optological records, he encountered two cases of the affection which directly militated against this view. He was fully impressed that these, from their paucity, were insufficient to support any practical or scientific position; but he thought that they fairly entitled the subject to reconsideration and more special scrutiny.

In Case I, a man, aged 34, long the subject of bronchitis and dilatation of the pulmonary tubes, death occurred after an aggravated attack, in which urgent dyspnoea was the most prominent symptom. During its progress, there was not any hæmoptysis. After death, nodular effusions of coagulated blood were detected in the lungs, and there was unusual patency of the tricuspid orifice. In Case II, a woman of 75 years of age, there were symptoms chiefly referable to the stomach, with ejection of dark coagulated blood a few days previous to the fatal issue. On examination, circumscribed hæmorrhagic effusions were presented in the pulmonary substance; and in this case also, the right auriculo-ventricular orifice was dilated. In neither instance, was there any trace of tubercular deposit in the lung.

Dr. Mushet proceeded to comment on the assertion of Andral, that pulmonary apoplexy was first described by Laennec; and stated, that Hohnbaum previously drew attention to it, and Haller also, sixty years before, in his *Opuscula Pathologica* (obs. 14, hist. i et ii), which were quoted. He next alluded to the meaning attached to the term "peripneumonia" by the older writers, as Boerhaave, Etzmüller, Willis, Sydenham, Sauvages, and Cullen. In referring to the etiology of (so-called) apoplexy of the lung, he

quoted Dr. Townsend, Laennec, Watson, Burrows, Walshe, Sieveking, and Fuller; and adverted to the omission of the disease from the recent works of Dr. W. Aitken and Dr. MacLachlan. He spoke of the occurrence of the attack at any age; and glanced at its connexion with tubercle and ordinary hæmoptysis.

Considering the discrepancy of views in reference to the proximate origin of pulmonary apoplexy, he ventured to observe that, in the cases he had adduced, the only common lesion was enlargement of the tricuspid orifice. Without endeavouring to establish a physiological explanation of the influence of this condition—if it exerted any—on the production of effusion of blood into the lung, he merely mentioned the pathological facts; adding that Bertin, Chomel, Bouillaud, and other French investigators, ascribed the affection to hypertrophous disease of the right heart—a change which ultimately entails dilatation and tricuspid incompetency.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, MAY 5TH, 1865.

G. POLLOCK, Esq., President, in the Chair.

ON THE PROGRESS OF THE HYPODERMIC TREATMENT. BY CHARLES HUNTER, ESQ.

THE author wished, in historically reviewing the subject, to show how extended in practice this treatment of disease had become of late years. The treatment of local affections by subcutaneous injection dated as far back as 1843,* when Dr. Alexander Wood proposed it in Edinburgh for neuralgia. Mr. Rynd of Dublin seems independently to have originated the same idea in 1844. For fifteen years—viz., from 1843 to 1858—these injections were only employed with narcotics for pain, and injected locally.

The author wished the difference between “the hypodermic treatment of disease” and “the narcotic injection of Wood” to be understood by the Society. The plans differed theoretically and practically. The method of Wood consists in localising the injection to the neuralgic site; and it was always theoretically considered beneficial through the localisation. The author’s method, proposed in 1858, differed theoretically and practically. He did not consider it necessary to inject the narcotic locally to cure neuralgia. He believed that the great effect gained was rather due to the mode of the medicinal introduction—the injection of the loose cellular tissue of the body. Six years ago he read the result of his experiments upon animals, showing how much more quickly and effectually the symptoms of the alkaloids injected were made manifest upon those parts of the system which they more especially influenced, than when introduced into the stomach. Practically, the author rarely injected the tender spot or neuralgic site (thought so essential by Dr. Wood), not deeming it necessary, and thinking it also more painful for the patient, and apt to engender local irritations if locally repeated. Cases of *tic douloureux* and of *sciatica* were given; in which the cure was effected by the distant injection—namely, into the arm. The cases have now remained permanent some years.

Thus, upon the theory of general rapid absorption, the door was thrown open for the treatment of diseases beyond the reach of local injection. The first and most important cases that Mr. HUNTER thus treated were cerebral affections. From the effects observed upon some well marked cases of mania and

delirium tremens, the author deduced that, by the introduction of narcotics into the cellular tissue of the body, we have a mode of attacking and subduing cerebral excitability more rapid, more certain, and more sure in action, than by stomachic doses.” (*Med. Times and Gaz.*, 1859.)

Mr. Hunter had had well marked instances, in which this conclusion had been verified in the treatment of cerebral affections—the cases chiefly being insomnia; melancholia; mania; puerperal mania; delirium; delirium *à potu*; delirium tremens; chorea; hysteria; etc. In all these diseases, the full beneficial effect of the alkaloid, whether morphia, codeia, or any other, had been obtained, without producing the constipation, the deranged tongue, the anorexia, the sickness, etc., which so often follow the stomachic administration. Sickness by the hypodermic dose was quite the exception, and had usually occurred from the injection of too large a dose.

The special advantages of the treatment in delirium tremens were—1, that the effect of the alkaloid could be at once enforced, although the patient refused to swallow; or 2, the stomach to absorb or digest, if he would swallow; and 3, that restraint, and the consequent cerebral congestion, were avoided.

In *spinal affections*, this treatment was indicated to remove pain; to arrest excessive, and to increase diminished, muscular action. The insomnia was an induced evil in these cases, but was not the one requiring the first attention.

In painful *spasmodic affections*, the spasm could often be relieved in a few minutes; as in retention of urine and in colic, etc. In tetanus, which disease the author was the first to treat by this plan, the hypodermic injection might both palliate and cure. Morphia would give sleep and ease the pain without really arresting the spasms; but atropia, woorari, and other agents, had relieved or cured patients in the hands of Vella, Briquet, Courty, Bernard, Follin, Spencer Wells, Benoit, Fournier, etc.

To arrest increased vascular action and inflammation, the author pointed out the value of hypodermic injections. He drew attention to the different effect produced upon the pulse with different alkaloids. These effects begun almost the instant the alkaloid was injected. Morphia would bring down a quick pulse to the normal standard, or below it, in ten or fifteen minutes; atropine almost invariably increased the pulse twenty to forty pulsations a minute in the same space of time.

To the value of this treatment for inflammations of the eye, of which the author gave an instance (*Medical Times and Gazette*, 1859), Dr. A. von Gräfe has amply testified (*Brit. and For. Med.-Chir. Review*, 1864.)

In peritonitis, the object with which calomel and opium are often long repeated, was gained at once by a full morphia injection; and so with other serous inflammations.

Of the use of this plan in the various forms of *uterine pain*, more especially of *dysmenorrhœa*, for which the author has used it with great advantage, Dr. Henry Bennet has testified in the *Lancet* (1864.)

In *fever and ague*, it had been shown by Drs. McCrall, Moore, Devigne, and others, that the same advantages attended the injection of quinine, as the author had originally shown to attend the injection of anodynes, narcotics, and nerve-tonics—namely, the greater rapidity of effect; an equal effect with a smaller injected dose than when given by the stomach, and the avoidance of the *desagréments* which sometimes attend stomachic doses.

Mr. Hunter objected to the way these medical men injected the quinine; namely, with a common syringe

* The subcutaneous injection of nœvi, hemorrhoids, etc., with caustics, dates a few years further back.

and a lancet to divide the skin! He exhibited various syringes; and showed the disadvantages and dangers that might arise from using a syringe not regulated carefully with a screw piston.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 9TH, 1865.

JAMES ALDERSON, M.D., F.R.S., President, in the Chair.

ON THE SURGICAL TREATMENT OF CERTAIN CASES OF ACUTE INFLAMMATION OF THE VEINS.

BY HENRY LEE, ESQ., F.R.C.S.

THE author stated that in Mr. Arnott's admirable paper on "Inflammation of the Veins", published in the fifteenth volume of the *Medico-Chirurgical Transactions*, he had drawn the inference that the dangerous consequences of phlebitis bear no direct relation to the extent of the vein which is inflamed. He had there proved by an excellent collection of cases, and by his observations on those cases, that death in cases of phlebitis does not take place from the inflammation extending to the heart, but from the entrance of some morbid product into the general circulation (pp. 44 and 61). In a paper by Mr. LEE, published in the thirty-fifth volume of the Society's *Transactions*, he had endeavoured to show that the material which obstructs the cavities of veins in cases of phlebitis is derived from the blood itself, and is not in the early stages of the disease a secretion from the lining membrane of the vessels; that the veins become extensively inflamed only in cases where coagula have previously formed; and that the purulent-looking fluid often found in the cavities of inflamed veins is derived from the changes which under the circumstances take place in the fibrine of the blood. The distinction which he wished to establish between the process by means of which fibrine is deposited from the blood, and that by which lymph is secreted from the lining membrane of a vein, was of primary importance, not only with regard to the pathology of this class of diseases, but also with regard to their surgical treatment; for it must be obvious that if the material which occupies the cavities of the vessels in cases of phlebitis were secreted by the inner coats of the veins, it would adhere firmly to that membrane, and would be found lining equally the whole circumference. It would not be displaced by the force of the circulation, nor by any other mechanical means likely to be employed. Moreover, the morbid process would extend by continuity of action, and would not be arrested by any surgical interference. If, on the other hand, the material found in the veins were derived from the blood, it might be expected to adhere slightly only to the walls of the vessels, to be attached to one part only of those walls, and to be removed easily by any mechanical force. It would be deposited in uncertain quantity and at irregular intervals, leaving portions of the lining membrane between those intervals free from deposit, and of its natural appearance. The deposit would often, as had actually occurred in some of the cases related by Mr. Arnott, terminate abruptly at the entrance of a fresh vessel; the reason of this abrupt termination being, as it appeared to Mr. Lee, the greater velocity and force of the circulation in the common trunk than in that which is partially obstructed.

Now the appearances actually observed on *post mortem* examinations in cases of phlebitis, all belonged to the latter and not to the former class; and the conclusion necessarily followed that the disease

extends, as far as its severer symptoms are concerned, not by continuity of action in the lining membrane of the vessels, but by means of their contents, often in a more or less perfectly coagulated state. If that were the true course of the fatal symptoms in phlebitis, it appeared surprising that more attempts had not been made to arrest the progress of the disease by surgical treatment. Such attempts, however, had not been entirely wanting. Hunter remarked that when inflammation takes place beyond the orifice (of a vein), so as to alarm the surgeon, he should immediately make a compress upon the vein at the inflamed part, to make the two sides adhere together; or, if suppuration have taken place, then the compress must be put upon that part of the vein just above the suppuration. (*Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge*, p. 29.) Now, as lymph was not effused in the early stages of phlebitis from the lining membrane as a secretion from its inner surface, the adhesion produced by Hunter's method of treatment could be formed by coagulum of blood only. This would not, under ordinary circumstances, become organised; it would adhere to one side only of the vessel, and it would constantly be liable to become displaced. Such a bond of union, although it might for a time prevent the morbid contents of a vein from entering the general circulation, could scarcely be looked upon as affording a permanent bond of union between the sides of the vessel.

In cases where the affected vein is seated superficially, a much more certain and effectual way of closing its canal and of barring the entrance of its contents from the general circulation might be adopted. This method, which when properly performed, Mr. H. Lee believed to be free from danger, was adopted in three out of four of the following cases. The fourth case was given as an illustration of Mr. Hunter's method of treatment. It would, the author thought, be obvious that, although Mr. Hunter's method might perhaps have been successfully adopted in the first case, it could not have been used with any reasonable chance of success in the second and third.

Four cases were then read in which, in severe cases of phlebitis, the current of blood was artificially arrested between the inflamed vein and the centre of the circulation. In one instance a pad was placed over the upper extremity of the basilic vein, and retained in its position by a bandage. In two cases a needle was passed under a healthy and unaffected portion of the vein, and pressure was made by means of a figure-of-S ligature; and in one case the vein above the seat of the inflammation was divided subcutaneously, the two divided extremities being secured by acupressure. Of these different plans of effecting the same object, Mr. Lee preferred decidedly the latter. In any future similar case it was that to which he should have recourse. By the operation of subcutaneous section a permanent union was effected, because that union took place between the opposed portions of cellular tissue on the outside of the vessel. Such a union was vascular, and therefore not liable to be broken down. By it no suppuration need be excited, and the needles used for the purpose of acupressure might be removed at the expiration of two, three, or four days, when the union would be complete. Union could not be ensured within the same period by the pressure of a needle placed under the vein. If the needle be removed at that time, the current of blood would be liable to be re-established through the vein; if it be left, suppuration might be excited on the outside of the vessel; this might lead to the coagulation of the blood both above and below the part where the vessel was compressed, and the coagula

thus formed might undergo the very changes which produced the serious symptoms for which the operation was undertaken. In one of the recorded cases this appeared in some measure actually to have happened, for although the current of blood through the vein was arrested, yet suppurative took place both above and below the needle last introduced. In another case, on the contrary, where the vein was divided, no trace of inflammation extended beyond the divided part. In both these cases the products of the diseased actions were expelled from the interior of the veins by the process of suppuration; but had the flow of blood through the vessels been allowed to continue, some of these same morbid products would have been carried in the course of the circulation, and would have produced their effects in other and distant organs.

Correspondence.

THE PHARMACOPŒIA OF 1788.

LETTER FROM THOMAS MARTIN, ESQ.

SIR,—As there has been of late a good deal of discussion respecting the last edition of the *Pharmacopœia*, our friends of the Association may have no objection to be informed of some particulars respecting the preparation and compilation of the edition of 1788, which I am able to supply.

At that time Sir George Baker was President of the College of Physicians. He and the rector of the parish of Pulborough, where I was born, and where my father was a general practitioner, were contemporaries at the university, and were intimate friends. Visiting at the Pulborough Rectory, my father had opportunities of seeing Sir George, who gave my father a copy of the new edition before it was issued to the profession and the public.

Sir George Baker, with the great Dr. Heberden and other heads of the College, were men of prodigious learning, so as to be very eminent at the universities and in the world of letters, as well as able physicians; but, as respected pharmaceutical knowledge, they felt conscious of their own deficiencies, and, knowing Dr. Fordyce's superior knowledge as a pharmaceutical as well as scientific chemist, they very wisely made him a Fellow of the College, of which he was previously a Licentiate only, and induced him to take charge of the new edition of the *Pharmacopœia*. The result was manifested in a reform of the nomenclature, as intended to denote the chief ingredient in each formula; and the formulae were much simplified in their composition. In fact, the codex became a perfect pattern of pharmaceutical reform.

In the accomplishment of this task, Dr. Fordyce called to his aid various sources of information, and was assisted by able men in that department; and, as he afterwards told me, he made various experiments on his own person as to the effects of *medicines*—not drugs, observe. I have already said that dyers and druggists deal in *drugs*: we deal in the *materia medica*.

I know nothing as to the cost or expense of bringing out this edition of 1788; but I dare say that it was very moderate. It was highly approved by the profession; and Dr. Powell published a translation of it, in an octavo volume.

I would now ask why the new medicines of inestimable value, adopted since the time I have mentioned, could not be comprised in a new codex with-

out so much controversy, and at a moderate expense. Previously to the time indicated, physicians' prescriptions were apt to be complicated; and their component parts were not always in accordance with each other; and I have no doubt that the new *Pharmacopœia* led to a simplification of prescription.

In the early part of my professional career, it happened that I came into contact and correspondence with Dr. Baillie, of whom highly honourable mention is made in Sir Benjamin Brodie's *Autobiography*, as being preeminent for his knowledge of morbid anatomy, his pathology, diagnosis, and treatment of disease. He highly approved of the *Pharmacopœia* of 1788, and was remarkable for the simplicity as well as efficacy of his prescriptions. Dr. Baillie's superiority in the treatment of disease became so manifest to all the world, that he was quite overdone with business; and he is said to have exclaimed, "What an unfortunate man I am! Everybody must have Baillie! No one can die without Baillie!" As he left his house to step into his carriage, at twelve o'clock, he would observe to persons desirous of seeing him, "I can see no more patients at home to-day." He was often waylaid, and his carriage stopped in the street. He was obliged to adopt several restrictions as to his practice. He would not go into the country, nor east of Temple Bar, nor up to Islington. In the City he was not wanted, as there was Dr. Babington, equally esteemed as a physician, and beloved for his virtues and excellent qualities. At the West End, the Sir Felix Fascinate of the day yielded to the superiority of Dr. Baillie, who worked the whole of every day and the half of every night. In his correspondence with myself, he never answered a letter by return of post, but invariably the next day. He could not afford to allow his correspondence to fall into arrear. When London went out of town, Dr. Baillie allowed himself a little repose in Gloucestershire. Such a case of the pre-eminence of one individual in the metropolis can never happen again. There are now many equally gifted, and with equal professional talents and attainments.

The same in the country. When I was young, the stars of the first magnitude out of town were, Hey of Leeds, Kerr of Northampton, Rigby of Norwich, and perhaps Cheston of Gloucester. Now there are hundreds of country practitioners equal to any emergency, medical or surgical.

These few recollections of an old practitioner may not be unacceptable to the readers of our JOURNAL.

I am, etc., THOMAS MARTIN.

Reigate, May 20th, 1865.

MINERAL ACIDS IN FEVER.

LETTER FROM F. C. HOWARD, ESQ.

SIR,—As Mr. Steele thinks that additional testimony to the value of mineral acids in typhus fever is needed, after that of such men as Murchison, Chambers, Richardson, etc., I beg to say that, for my part, I am quite satisfied that no other plan of treatment in fever will bear any comparison with it. During a period of thirty years, I have had a great many cases under my care, and have tried various plans of management; but the death-rate under the acid treatment has wonderfully improved; and of 120 cases of low fever recently treated after Dr. Chambers's plan, not a single patient who took the acid died. Wine was used, but not largely. The acid was felt to be, both by patients and by myself, of greater value than even wine or brandy. If the acid were omitted, and the case left to proceed under wine alone, an aggravation of symptoms invariably

resulted; whereas, the loss of the wine during the use of the acid seemed to be less, if at all, felt.

My experience, then, would seem to corroborate the opinion of Dr. Murchison, who considers the acid treatment superior to any other in fever, and also that of Dr. Chambers, who tells us in his Lectures, that during several years he has never lost a case of fever in which the acid had been exhibited for thirty-six hours.

As to the *rationale* of its action, Dr. Richardson's hypothesis, as founded on facts, seems to me sufficiently satisfactory; but who would cast aside bark in ague, or acids in purpura and scurvy, because they were used empirically?

If Mr. Steele would kindly put the cases of fever which he may meet with during the next few months, under the acid treatment, and give us the result, I am sure that his testimony would be valued as that of an observer unbiassed in its favour; but I would beg of him to use the acids according to the plan of Dr. Chambers, whose success in the treatment of fever is so well known.

I am, sir, etc.,

F. C. HOWARD.

Linton, May 25th, 1865.

LETTER FROM PERCY LESLIE, ESQ.

SIR,—Drs. Murchison and Steele, in their late communications on continued fever, speak of it, and certain theories connected with the nature and treatment of the same, as might at first sight lead one to suppose that these were not equally true of nine-tenths of all other diseases. For, after removing the cause, our operations are mostly confined to aiding nature in the combat against disease: first, by preventing everything that would hinder, and secondly, by promoting everything that would assist, a restoration of that dynamical equilibrium we call health. In other words, we look upon the body as a self-adjusting machine and treat it accordingly—equally so in all its ailments, fevers included. True, there are a few antidotes and specifics put providentially into our hands, which enable us to say of some complaints that a cure is effected. To these it is always our ambition to add; and from time to time it will be permitted us to do so, when fevers, from their having for the most part a specific origin, will, without doubt, have a better chance of being introduced into that category, than the vast variety of disease produced by more ordinary and universal operations of nature.

Dr. Murchison mentions Mr. Steele's paper to have for its object, "to show that not only is there no specific for fever, but that, as Dr. Corrigan has observed, in the present state of our knowledge, there can be no specific for this disorder." This means, either that our present state of knowledge gives us no specific for fever, which may be true; or else, that our present knowledge of the nature of fever precludes the possibility of such being discovered; but such a statement does not by any means prove that the wisdom gestating in the womb of the future should be equally debarred from making so desirable a discovery.

I am, etc.,

PERCY LESLIE.

Eastbourne, May 30th, 1865.

THE FEVER EPIDEMIC IN ST. PETERSBURG. The *Russian Correspondence* of May 9th says:—"The number of sick, which had considerably diminished in April, has again increased during the second Easter week. This arises principally from the affluence of the workmen in the building trade, who began to arrive about this period. Notwithstanding the recrudescence there is no want of room in the hospital."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on May 11th.

Bell, Anthony, Newcastle-on-Tyne
Broughton, Robert David, Ruyton, near Shrewsbury
Buggen, Richard, Tenterden, Kent
Cremolini, John, Bilston, Staffordshire
Fawcitt, Thomas Joseph, Newcastle-on-Tyne
Harrison, Henry Edward, Great Ormond Street
Powne, Benjamin Lamb, Billingham, Lincolnshire
Pratt, Thomas Gray, March, Cambridgeshire
Ruttledge, Edward Butler, Ingatstone, Essex
Shepard, William Lively, Gray's Inn Road
Shoolbraid, David, Duff Town, Banffshire
Spilsbury, Thomas Hamilton, Sierra Leone
Thomas, Oliver Dillon, Pontypool

Admitted on May 23rd—

Aveling, Charles Taylor, Shacklwell
Boulton, Edmund Farrington, Bath
Cass, William Cunningham, Cowes, Isle of Wight
Conry, Thomas, Dublin
Dawson, William Baines, Brentwood
Dunn, John Roberts, Warbleton, Sussex
Fennell, Theodore, Rain Hill, Lancashire
Hawett, William, Wigan, Lancashire
Hughes, John Pearson, Llandover, South Wales
Lyle, Henry Bowden, Ashburton, Devon
Martin, William Young, Little Hulton, Lancashire
Milward, James, Bristol
Nearne, Thomas Albert, Hungerford, Berks
Owen, David Charles Lloyd, Smethwick, Birmingham
Percy, George, Dublin
Roper, Robert Gear, City Road
Spooner, Charles Henry, Newington, Surrey
Whiting, James David Charles, Upper Ebury Street
Worthington, James Copland, Lowestoft
Yeats, George, Aberdeen

Admitted on May 24th—

Lethbridge, Charles Frederick, Torquay, Devon
Noel, Vincent Edmund, Devonport
Powell, John, Chichester
Reeves, Henry Albert, Newbury, Berkshire
Tilton, John Edward, Stonehouse, Gloucester
Walls, Albert William, Bayswater

At the same meeting of the Court—

Mitchell, John Frederick, H.M.S. *Lizard*, Sheerness, passed his examination for Naval Surgeon, his diploma of membership being dated March 14th, 1866.

APOTHECARIES' HALL. On May 25th, 1865, the following Licentiates were admitted:—

Elliot, David, Newcastle-on-Tyne
Hickman, Richard Nurhall, Seaton, near Salisbury
Ward, Frederic Henry, Finchley Road, Walworth
Wilby, John Burdett, Leicester

BIRTH.

WILLIAMS. On May 25th, at 13, Newhall Street, Birmingham, the wife of *T. Watkins Williams, Esq., General Secretary of the British Medical Association, of a daughter.

DEATH OF MR. WATERTON. The papers announce the death of the well-known traveller and naturalist, Mr. Waterton, in his eighty-third year.

MR. THOMAS MARTIN. Our respected associate, Mr. Thomas Martin, on the 24th ult. presided at the annual meeting of a society in Surrey founded by Mr. Martin himself fifty-three years ago!

DEATH UNDER CHLOROFORM. A lad, aged 13 years, died on the 19th of May, at the Ophthalmic Hospital, Bloomfield Street, City, from syncope, while under the influence of chloroform.

SOCIAL SCIENCE ASSOCIATION. The ninth annual meeting of the National Association for the Promotion of Social Science will be held at Sheffield from the 4th to the 11th of October next.

NON-COMBATANTS (?). Dr. Ungar, a surgeon in the Austro-Mexican army, lately died in the hospital at Vera Cruz, of wounds received in combat with guerillas. The Belgian papers, amongst the number of killed of a Belgian regiment in the Mexican army, give the name of Surgeon Lejeune.

THE RATE OF MORTALITY last week was 22 per 1,000 in London, 24 in Edinburgh, and 20 in Dublin; 29 in Liverpool, 29 in Manchester, 20 in Salford, 18 in Birmingham, 27 in Leeds, 22 in Bristol, 19 in Hull, and 29 in Glasgow. The rate in Vienna was 42 per 1,000 during the week ending the 13th ult.

THE ALKALI ACT. The first Report of Dr. Angus Smith, the chief inspector under this Act, has been lately presented to Parliament. Lord Derby, in commenting on it, congratulated himself on the perfect success of the measure, and paid a deserved compliment to Dr. Smith.

THE ARMY AND NAVY MEDICAL OFFICERS. In consequence of a requisition signed by upwards of twenty Fellows, the President of the Royal College of Physicians of London has called an extra-ordinary general meeting of the College for the 5th inst., for the purpose of reconsidering the question of the army and navy medical officers.

THE ORDER OF THE BATH. The Queen has appointed Surgeon-Major William Munro, M.D., 93rd Regiment, and Surgeon-Major Henry Bruges Buckle, 1st Punjaub Regiment of Infantry, to be Ordinary Members of the Military Division of the Third Class, or Companions of the Most Honourable Order of the Bath.

CARRIAGE ACCIDENTS. The following fatal carriage accidents were registered during the past week in London. A widow, aged 80 years, was run over by a van in the Farringdon Road. A corkenter, aged 72 years, was run over by a cart. A gardener, aged 73 years, was run over by a vehicle. A labourer, aged 25 years, was run over by a cart in the Dover Road. A carter, aged 34 years, was run over by a wagon at New Cross.

THE ROYAL SOCIETY OF ENGLAND. Only fifteen candidates can be elected annually. Of these, only three are ever put in for chemistry, and three for astronomy; whilst medicine and natural history also occasionally have three fellowships given to them. This year chemistry and geology have each only one fellowship; natural history has three; astronomy three; medicine and engineering have each two; mathematics, literature, and Arctic discovery have each one. In all there are 675 Fellows.

GREENWICH HOSPITAL. In a discussion in the House of Commons on Tuesday last, Sir John Pakington said that he was informed that it was intended to place this magnificent establishment on the footing of Haslar or Netley, and convert it into a mere hospital in the ordinary sense of the word. He wished to know why the engineers and surgeons of the navy had been excluded from the list of those who were to receive pensions. Mr. Hennessy said that the Commissioners in their report stated that there was one branch of the establishment in which no reformation was required—the medical branch. He would ask, therefore, how it was that medical officers in the navy were excluded from participation in good service pensions. Mr. Childers replied, that the honourable member for King's County had truly stated that the doctors had been favourably reported upon by the Commissioners, and the Admiralty were not going to take away any part of their employment. On the contrary, they would probably be more fully occupied than at present.

APOTHECARIES' HALL. The next "examination in arts" will be held on the last Friday and Saturday in September. The subjects will be the same as at the April examination, except that, in Latin, Virgil's *Æneid*, Book VI, will be substituted for *Caesar De Bello Civili*, Books I and II. The examination for the society's annual prizes for proficiency in the knowledge of botany (systematic, descriptive, and physiological) will be held on the second Wednesday in August. The examinations for the prizes in materia medica and pharmaceutical chemistry will be held on the third Wednesday and following Friday in October.

MEDICAL CANDIDATES FOR CORONERSHIPS. Mr. Wilson, the medical candidate for the coronership of Leeds, has been defeated by Mr. Emsley an attorney. The causes of Mr. Wilson's failure we know not; but we trust that the lukewarmness of his medical brethren is not accountable for it. Mr. Carr, whom we announced as a candidate for the coronership of South Northumberland, has retired from the contest, and left it in the hands of the lawyers. We regret to hear that in this case medical gentlemen were actively engaged canvassing in behalf of the lawyer as against their own medical brother. *Sic semper! alas!*

A HOMŒOPATHIC CHALLENGE. Mr. Clifton, a homœopathic practitioner, has addressed a proposal to the governors of the Northampton Infirmary. "As the expenditure of the Northampton Infirmary," he says, "exceeds its income by the annual amount of £200, I will guarantee to provide that sum annually, on the condition, that the governors will appropriate the fourteen beds in the Convalescent Hospital, or an equal number in the Infirmary, for the reception of medical cases, to be treated homœopathically; and for such cases, I will undertake to provide the necessary medicines, and a dispenser, free of cost to the institution." He asks this, 1. As a matter of justice to those governors who adopt homœopathy, and to the poor who prefer being treated according to that system; 2. Because homœopathy has been proved to be much more successful than the older system; and 3. That cases considered incurable by allopathy may have the benefit of trying homœopathy and *vice versa*. During the past year several cases pronounced incurable have left the Infirmary, and have been cured at the homœopathic dispensary."

TOO MANY LECTURES. On the defects of the modern method of study, Sir Benjamin Brodie held strong opinions, which may be summed up in the statement that students now-a-days are made to attend too many lectures. He used to congratulate himself on the fact that his professional education belonged to the past and not to present times; that, in short, he lived under a system which permitted him to educate himself. He got the greatest benefit in the way of instruction from a diligent attendance in the dissecting-room and in the wards of the hospital; and he glories in the remembrance that he did not attend "one-fourth of the number of lectures which the unfortunate students are now required to listen to under the direction of the constituted authorities." He points out that he was not alone in his dislike of lectures. Abernethy used to complain that Brodie's distinguished contemporary, Mr. Lawrence, now the chief surgeon at St. Bartholomew's, would not attend his lectures. "I can easily conceive," adds Sir Benjamin, "that if I had been compelled to sit on the benches of a theatre four or five hours daily, or tempted to compete for prizes as students are, and to get crammed for various examinations, my position in life afterwards would have been very different from what it has been in reality."

CORONER'S INQUESTS. Dr. Lankester, the coroner for Central Middlesex, has sent in a second annual report from August 1st, 1863, to July 31st, 1864. It appears that there were held in his district 1,271 inquests in the year, making 191 inquests more in the last than in the former year. This increase is due to the increase of population, and the increased vigilance of the summoning officers. One of the most noticeable features in the returns, says Dr. Lankester, is the increase of inquests under the head of accidental deaths, which amount to the large number of 70 cases. He attributes the increase of accidental deaths to the increased traffic in the streets of London; and to the enormous development of building industry in the centre of London. The increase of verdicts under the head of suicide and homicide is not greater than may be accounted for by the increase of population. The diminution of verdicts of "death from unknown causes, may be accounted for by juries more frequently returning verdicts of "wilful murder" in the case of newly born children found dead in the streets. A table gives the number of inquests held in hospitals, prisons, and lunatic asylums in the central district of Middlesex. This table shows that while the number of inquests held in St. Mary's Middlesex, and University College Hospitals have been nearly the same, there has been a large increase at the Royal Free. The Great Northern, which during the previous year had been removed from King's Cross to the Caledonian Road, Islington, and received no in-patients, has reopened its doors, and gives for the past year five cases. The increase of cases in the prisons is remarkable. In these places an inquest is held on every death, from whatever cause. The inquiries in workhouses are, perhaps, fewer in proportion to their inhabitants than in asylums; and this may be accounted for by the fact that no notice of death occurring in workhouses is required to be given to the coroner. As the coroner's inquiry is, no doubt, a great protection to those who die in prisons and lunatic asylums, Dr. Lankester thinks it a question well worthy of consideration, in view of the helpless condition of the great majority of the inhabitants of workhouses, as to whether the coroner's inquest should not be held in all cases on persons dying in workhouses, or, at least, that all certificates of death should be referred to the coroner. There is one class of accidents which presents a decrease; and that is the class which occurs on railways. The difference between the number of deaths from suicide in the two years is so slight as to indicate on the whole that the causes which lead to this disastrous occurrence have been the same in the two years. The methods of self-destruction employed have differed very considerably in the two years. Thus, in the years 1862-3 there were 19 cases of poisoning, while in 1863-4 there were but nine. There was but one instance of poisoning by opium in the latter year, against four in the previous year, and two cases of poisoning by oxalic acid in the second year against five in the first year. The only poison employed in the second year which was not used in the first is corrosive sublimate, while strychnine, sulphuric acid, prussic acid, and potash which were answerable for six deaths in the first year do not appear in the list of the second. Our legislation was at one time ferocious with regard to the destruction of human life. A reaction took place, which has placed us in our present position, in which upwards of 150 dead children are annually found in the streets of London. It is not too much to suppose that where one child is found another is successfully hidden for ever. In cases where the mothers have been discovered their ages have averaged about 20 years; as it is not to be supposed the same woman commits this crime a

second time, and as the expectancy of a woman's life at 20 is 40 years, this would give the large number of 12,000 women living in London alone who have thus secretly destroyed their offspring." In conclusion, the coroner draws attention to the general want in London of better and more convenient houses for the dead, those attached to workhouses and for parochial use being generally inconvenient and deficient in light, ventilation, and the requisites for making *post mortem* examinations. He thinks it would be most desirable to erect deadhouses in every parish, so that the poor who have but little room in their residences might be able to deposit their dead until the time has arrived for the corpse to be buried, thus avoiding the production of disease, and the tendency to demoralisation produced by the presence of the living and the dead in the same room.

ALCOHOL. Dr. Munroe, F.L.S., lately gave a lecture to the Hull Band of Hope Union. Numerous chemical experiments were performed by the lecturer to show that alcohol was not assimilated in the tissues, and could not, therefore, afford the slightest nourishment, being eliminated as alcohol just the same as it entered. He did not wish his paper to partake of the character of a teetotal lecture, but rather that of a scientific inquiry into the mode of action of alcohol when introduced into the tissues of the body. The all-important question to be answered was, What was alcohol? Was it food, or poison, or medicine, or a luxury? The researches of physiology and modern medical science proved that perfect health could only be preserved by total abstinence from all intoxicating drinks; because alcohol, for the time being, had the peculiar power of disarranging the natural functions of the body, and producing a morbid condition of the tissues with which it came in contact. Every writer on the subject of toxicology had classified alcohol as a narcotico-irritant poison. Having traced the career of alcohol from the mouth and stomach, and found that it was not nutritious, nor yet even friendly to the functions of digestion or nutrition, the lecturer drew attention to the microscopic appearances of the blood, showing how speedily elements of diet, medicinal substances, and poisons were found in the liquor sanguinis, and how the corpuscles of the blood became affected by these various agents, especially by alcoholic drinks. Alcohol deteriorated the liquor sanguinis, and also stimulated the blood-vessels to an unnatural contraction, which induced their premature death. The colouring matter was dissolved out of them, and the pale discs lost their vitality, whence less oxygen could be absorbed, and less carbon carried out. Particular reference was made to a very frequent cause of disease from the habitual presence of alcohol in the circulating medium; viz., fatty degeneration. Three-quarters of the chronic illnesses medical men had to treat were occasioned, Dr. Chambers said, by this disease; arising, no doubt, from the universal practice of daily stimulation. The lecturer referred to the effects of alcohol on the cerebrum, showing that the brain was more liable to disease from alcohol from the fact that alcohol selected that organ on which to spend its chief action. Lallemand and Perrin proved that alcohol produced in all persons an intoxication which was marked by a progressive series of functional disturbances and alterations, the intensity of which corresponded with the quantity of alcohol taken. The lecturer had come to the conclusion—1. That where the body was free from disease, and the brain in a healthy condition, the psychical or moral portion would have full power to keep in check or overbalance the passions for evil; 2. That when the brain had become poisoned with alcohol, which, by a peculiar

elective affinity, selected certain special ganglia of the brain, whose functions it deranged, the resisting power of the will for the time being became impaired or weakened, and the man became powerless against the temptations which beset him; 3. That if the brain were continually under the influence of alcohol, the power of the will became lost, and the patient relapsed into a confirmed dipsomaniac—a pitiable spectacle of drunken insanity.

GREENWICH HOSPITAL. A writer in the *Times* makes the following remarks:—The Seamen's Hospital Society have decided to abandon their floating hospital, the *Dreadnought*, and have purchased from the Greenwich Hospital Commissioners, for £5,500, a site adjacent to Greenwich Hospital, and are about to spend the greater part of forty-four years' savings and benefactions, at least £60,000, in erecting, within a stonethrow of the ancient and now half-vacant Greenwich Hospital, a new hospital to hold three hundred beds. This Seamen's Hospital Society, which has purchased a site, and is about to build at the very doors of Greenwich Hospital, was instituted in 1821, and incorporated by Act of Parliament in 1833. It is a hospital where the wounded are healed and the sick are cured. It is open to every comer. It is aided by Royalty and by our principal shipowners, and has for forty-four years been most popular. The legacies and donations given to it amount to more than £100,000. The Admiralty provides it with a ship. It seems to be a model of economy. But the Seamen's Hospital Society could not relieve all the cases of distress occurring in that class. Nine of the London hospitals relieved in 1863, three hundred and ninety-one sailors as in-patients. If the four other general hospitals were included in this return, we should have to add about one hundred and fifty more. It is stated by the officers of the Floating Hospital that sailors now prefer to be cured on shore. On shore they find ampler space and increased comfort, and "they have had enough of ship", they say at sea. Is it necessary to say more on behalf of the claim of the Seamen's Hospital Society, to occupy a portion of Greenwich Hospital. The present Infirmary of Greenwich Hospital contains room for nearly three hundred beds. In King Charles's and King William's quarters, which form the two western divisions of the main building, there is room for about five hundred and fifty more beds. Why should not the eastern moiety of the Hospital, composed of Queen Anne's and Queen Mary's quarters, be assigned at once to the use of the Seamen's Hospital Society, for the benefit of the mercantile marine? The report of the visiting surgeon to the society, framed with exclusive reference to the contemplated scheme of a new hospital to be built on shore, contains the following passage:—"A hospital establishment consisting of isolated buildings at some distance apart from each other, in a quiet, airy situation, would represent perhaps the best type of hospital; but it is clear that a hospital erected in such a situation would for most purposes be next to useless, and would be enormously costly." Greenwich Hospital is built precisely on this principle of isolation; it is quiet, and very airy; it is composed of five entirely separate portions; two, if not three, of these piles of building will soon be absolutely vacant. They can be had without cost; let us try their utility.

BOOKS RECEIVED.

1. The Why and the Wherefore of Cattle Diseases. By William Reid. Edinburgh and London: 1865.
2. Selection of Documents and Autograph Letters in testimony of the Cures effected by the Electro-Chemical Bath of J. F. I. Caplin, M.D. Translated from the French Edition. With an Appendix. London: 1865.

OPERATION DAYS AT THE HOSPITALS.

MONDAY......Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TUESDAY.....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.

WEDNESDAY....St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.

THURSDAY.....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.

FRIDAY......Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

SATURDAY.....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."—Epidemiological Society, 8 P.M. Deputy Inspector-General Smart, M.D., R.N., "On the Dengue (Break-bone Fever of Hot Climates—the Scarlatina Rheumatica of Dr. Copland)."—Entomological.

TUESDAY. Anthropological Society of London, 8 P.M.

WEDNESDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."—Obstetrical Society of London, 7 P.M. Council Meeting. 8 P.M., Adjourned Discussion on Dr. Barnes's paper on Dysmenorrhœa due from a Peculiar Form of Cervix; also, a Supplement to the same, by Dr. Barnes. Case of Extruterine Fœtation, by Dr. J. Braxton Hicks. Cases of Hydatidiform Degeneration of Placenta with Albuminuria, by Dr. B. Woodman.—Geological.

FRIDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."—Astronomical.—Royal Institute.

TO CORRESPONDENTS.

* * All letters and communications for the JOURNAL, to be addressed to the Editor, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

A CORRESPONDENT reminds us that the gentleman alluded to in the JOURNAL of May 20th, in connection with Hospital Conveyances for the Sick, is not Mr., but Sir Macdonald Stephenson, the well known engineer.

NUMBER IV OF THE ARCHIVES OF DENTISTRY, edited by Mr. E. Truman, contains a paper by Mr. Bate on Filling Teeth with Gold. Mr. Truman continues his series on Mechanical Dentistry in England. Dr. Richardson has a Chapter on the Teeth and Mouth in Idiots. There is also an interesting account of the Replantation and Transplantation of Teeth, translated from the German of Dr. Mitscherlich.

FEES FOR VACCINATION.—It would appear from the following directions, issued some years ago by the Poor-Law Board, that medical men can claim fees for re-vaccinations; in fact, for all successful cases of vaccination. The Assistant Secretary writes:

"The Poor-Law Board direct me to state that, in accordance with the contracts entered into by the guardians in pursuance of the statute 16 and 17 Vict., cap. 100, the public vaccinators are entitled to be paid for the successful vaccination of any person resident in the union whose name is entered in the register provided by the guardians, in accordance with the contract. There is no limitation as to age, nor is it material that the persons had been previously successfully vaccinated."

An Address

DELIVERED AT THE

DISTRIBUTION OF PRIZES AT ST. MARY'S
HOSPITAL MEDICAL SCHOOL.

On Monday, May 29th, 1865.

BY

RICHARD OWEN, D.C.L., F.R.S.,
ETC.

I HAVE been honoured by the request, through the Dean of your School of Medicine, to deliver to the successful competitors the prizes which they have gained by excellence and proficiency in the studies of this school; and here, at the outset, I am led to note the sound judgment which has governed the definition of the field of competition. With a few exceptions, prizes are not awarded for single courses; but classes are grouped in accordance with the curriculum laid down for students of the first and subsequent years; the object being to ensure the general proficiency of the students of each year in their respective subjects of study. I am happy in being permitted to take part in an assemblage and on an occasion that have for their essential cause and condition the increase and diffusion of knowledge. I am favoured in being the instrument of manifesting the satisfaction which the teachers of science in this school feel in the success which proficiency testifies to their endeavours to impart such science. I am glad also to meet fellow-learners of every grade, whose main aim and labour profess to be to gain those steps in science which may lead them to a height whence, in their turn, perhaps, they may discern the signs by which our view of the field of knowledge may be expanded.

In every race, one wins, or a few gain prizes; but every competitor has earned in the course what far transcends in value the mark of some small relative superiority. In the training or preparation for mere physical excellence, the muscular fibre is strung, the capacity of respiration developed, the vigour of circulation increased, the whole bodily health improved; the organism is a better organism, can do greater things, can receive higher enjoyments. But these perfections subside with the cessation of the exercises that educed them. Yours has been a competition of a higher kind; not of the powers of the animal, but of those of the man; not of the body, but of the mind; and the gain in the training and very act of competition must have been proportionate. Moreover, in the friendly endeavours to excel in which you have been engaged, you have done more for your own advantage and that of mankind than merely improve the working of your own intellects. The very exercises by which the acquisitiveness of ideas, retentivity of facts and principles, power of comparison of grounds for this or that conclusion—in short, any of the faculties of apprehending truth, have been improved or educed; have left you in possession—permanent possession, let us hope—of the elements of anatomy, physiology, chemistry, zoology, botany, and other definite kinds or sums of natural science, which go to endow you with the faculty of compre-

hending the nature of injuries and symptoms of disease, and of applying that power in behoof of your suffering fellow-men.

Now, the lowest amount of this intellectual wealth which may have been gained and garnered by the student is to him a prize far exceeding in value the signs and tokens of honour which I have had this day to distribute. Let not, then, any of the so-called "unsuccessful" repine or feel discontent at the issue of the competitions. He has gained a better possession, in whatever measure he may have mastered the sciences which he has had the opportunity of learning; he has succeeded in a far higher matter, if his conscience tells him he has done his best, and has neither wantonly nor wilfully thrown away his opportunities. As our great poet sings:

"Fame is no plant that grows on mortal soil,
Nor in the glittering foil set off to the world, nor in broad
rumour lies;
But lives and spreads aloft in those pure eyes and perfect witness
of th' all-judging Jove:
As he pronounces, lastly, on each deed,
Of so much praise in heaven expect thy meed."

But, to descend from these heights to things of less empyreal concern: let me congratulate you on your being students of St. Mary's Hospital and School of Medicine, and show cause of congratulation by reference to the opportunities, arrangements, and conditions which it affords for a sound and thorough scientific and practical medical education.

[The chief characteristics of these were then defined and commented on.]

It is sometimes asked, Is medicine a science? This question, like many others, is hardly reasonable or fair, the two terms being so unequal in degrees of complexity. So far as medicine knows the cause and condition of a curable disease, and the one infallible cure, to that extent it is "science". If medicine has mastered the nature of a specific malady, if there be a specific malady, and has discovered the specific remedy, if there be such a thing as a specific, it may claim to be a science. I leave to the experienced practitioner to determine what may be the proportion of the field of observation and practice commonly called "medical science" which is in the above defined condition; and what the proportion of that field in which the cultivators differ in their views as to the cause, the nature, and the remedy of disease.

Your excellent professor of chemistry will tell you that, having a special aim in view, he adds a certain reagent to a given solution or mixture, knowing that it will produce such desired result; viz., a certain infallible decomposition and recombination. The prevision and its fulfilment prove that he possesses a science. But, were other chemists to affirm that a different reagent would produce the same result, or that the solution, if left to itself, would produce it by spontaneous decomposition or recombination; and if there were really grounds for such affirmations or diverse views of the case,—you would then conclude that chemistry had not reached the scientific stage, and would hardly expect it to enjoy public confidence.

In fact, we see at the present day that the public confide not so much in medicine as a science as in the particular practitioner. It is characteristic also of the present phase in the growth of medicine, that the public are liable to be deluded and led astray by its shams; and not until medicine becomes a science can such simulacra be expected to vanish, and quacks and quackery to become extinct. Time was when disasters were deemed, in the literal sense of the term, to be the effect of malign influence of stars. Two or three centuries ago, the horoscope was cast, and believed to indicate the future destinies of the heir, by the same classes as now accept, in like faith,

the infinitesimal globule. The astrologer then had leave to move in the same social scale, and to sit at the same tables, as now the homeopathist. Astronomy had not risen to its full development as a science. It is interesting, indeed, to consider how a public, ignorant of and careless about the grounds and proofs of an established science, does in time come to believe in and trust it, to the exclusion of its simulacra, and the utter deposition and extinction of the quack professors of the same. I believe the public gain this faith by what the true science effects, and what it predicts.

By means of the data of astronomy, the seas are navigated, and remote parts of the earth reached with marvellous exactitude. Astronomy foretells phenomena to the day, hour, minute, even second of time: the interval—it may be years—after the prediction passes; and at the very hour, and fractional part of the hour, the event foretold comes off.

The palæontologist, from a fossil fragment, infers that such a form of animal, strange, it may be, or gigantic, has existed in such an island; and commits himself a prophetic sketch of the same. Other parts are afterwards found; at length, perhaps, the entire skeleton. The public knows nothing of the laws of correlation by which the prevision of a form of life long passed away, and never seen by human eye, was gained; but it is struck by the fulfilment, and accepts or believes in the science.

Medicine is occasionally called upon to prophesy in public: the rank of the patient requires a bulletin. Reference to some of these series of predictions and the actual results may partly account for the degree in which medicine still halts, as a science, in public estimation. And so it comes to pass that the question continues to be asked, "Is medicine a science?"

The great question for you, however, is—Can medicine become a science? From every analogy of the progress of human intellectual endeavours to raise, by observation and experiment, a body of facts and phenomena to the status of true science, the reply to the latter question would be emphatically, Yes!

Anatomy, physiology, pathology, or a knowledge of deterioration of structures, to the minutest degree in which the microscope can show such changes for the worse, in the fluids and elementary tissues of organs; chemistry, especially organic; the nature and powers of medicines—in short, all those bodies of doctrine worthy of the name of science, and which bear upon the problem of life, must be cultivated—if possible mastered—as the indispensable basis on which a lasting superstructure of a true science of medicine can be raised. Medicine can only become science by and through the subservient bodies of doctrine that have become science—the unknown must be reached by the known.

In every age, the individual who has effected most to raise medicine and surgery to the rank of sciences, has been the practitioner who was most distinguished for his knowledge of science.

John Hunter, besides being the greatest surgeon of his time, was the best physiologist, the greatest comparative anatomist, and, what was then little if at all known to his compatriots, he held the most advanced views of zoological classification, and was the most experienced palæontologist.

In considering the obstacles that impede the progress of medicine to the scientific status, I have been led to regard in that light, among other opposing influences, "fees" and "examinations".

Taking poor human nature as it is, I suppose that, if the palæontologist were to receive his *honorarium* for every fossil he gave an opinion on, the number of

mistaken determinations would be enormously increased. Were the chemist to make his analysis with a view to the fee, he would be diverted and led far astray from the track of discovery. If the zoologist might claim and receive pecuniary reward for every new insect, shell, or worm, he might characterise the number of "nominal species" would be vastly on the increase. Nature will not be bribed to reveal her secrets; hardly will she, and rarely, reveal them under the torture of vivisectional experiment. She demands the full and entire devotion of her suitor, in long years of subservient observance; and only to such single-minded worshippers of truth will she whisper a particle of it.

The physician who, in our day, has, perhaps, done most towards rendering medicine a science, is Rokitsansky, through the very great proportion of his time devoted to the study of eleemosynary cases.

The same condition of advancement exists in the relations between the patients in hospitals and the medical officers. But for the entire range of maladies, in the various classes of society, one is disposed, in reference to the advance of medical science, to indulge in the Utopian desire of the devotion of some one adequately gifted in mental power and material wealth to the study of disease, exclusively with a scientific aim; able to select his cases; not necessarily diverted from a given and promising line of observation by the calls of remunerative practice.

Thus, in the same malady affecting different individuals under similar conditions of age, sex, temperament, or constitution, the effects might be compared, of the customary or accepted remedies in one case, of the remedies of an opposite kind—conditions of practice which in some instances now divide the medical mind—and of the withholding all medicines: just as the chemist, in quest of discovery alone, perseveres in the pursuance of the analyses of a particular class of compounds, his faculty of insight being sharpened in relation to them, by exclusive study and progressive familiarity with their specialities.

In reference to the second of the obstacles which it has occurred to me to specify, I do not mean "examinations" in the abstract; but the kind and conditions of those tests which more immediately affect the sciences—as taught, e.g., in a school of medicine like St. Mary's—and the ultimate aim which the teachers have in view.

Examinations differ widely, in the work and qualifications of the examiners, in the views and motives of aspirants to the office, in the main end and aim of the test itself. In regard to the latter, the difference is such that it may be expressed by saying that some examinations are conducted to find how much, and others how little, a man knows. In the first category, those examined are ranked in the order of their acquirements; in the second, all alike receive a diploma, signifying qualification. And, as the weakest link in a chain gives the strength of the whole, so the scantiest measure of knowledge that enables the candidate to pass, becomes that of the amount sought for by the examiners, and at the same time a test of their own qualifications for the office, and of the responsibility and trouble which they undertake in its performance.

To exemplify the first kind of examinations, I would refer to the well-known arrangements at our old universities, in principle so pure, so effective in arrangements, as to gain for him in whom the highest amount of knowledge has been found the unhesitating applause of the less successful, which is echoed, without the slightest misgiving, by the country at large.

In the composition of the examining body, old experience is combined with young vigour, soundest knowledge of settled principles, with minds fresh from the latest discoveries and amended views of science. The senior wrangler of one year may be associated with his teachers as an examiner in the next.

The machinery is effective without being cumbersome. There is no inducement to make it so. Four is the usual number of examiners. The administrative authorities of the university, responsible for the well working of the examination, impressed also by its supreme importance, have no other notion than to make it work well. They do not propose to themselves any personal advantage, in purse or dignity, by taking part in the work. They simply elect the best men for it. These, likewise, are moved by considerations far higher than the emoluments of the office; and, indeed, there are none. Such fee as may be offered and received simply nullifies the sense of obligation, on the part of the authorities, for the time and labour devoted by the examiners to the duties confided to them.

The annual lists of the results of the B.A. examinations at Oxford and Cambridge exemplify the operation of this system of examination, in discovering the relative amounts of knowledge in the candidates. The teachers of the required subjects are stimulated thereby to impart the newest discoveries, and to set intelligibly before their pupils the latest phase of their respective sciences. "Examinations" of this nature are helps, not hindrances, to science.

A board of examiners composed exclusively of old teachers or practitioners, and to whose diploma or pass-certificate the bulk of medical students look as a main aim of their metropolitan studies, becomes an influential element in the consideration of the way in which, *e.g.*, anatomical and physiological science is to be presented by the teacher to his class. I believe that I do not err in supposing that, if the examinations in human anatomy and physiology by the board granting the diploma were conducted by a combination of young cultivators of those sciences with the experienced practitioner for the surgical department; that if one or more men of justly merited public repute for their advancement of anatomy and physiology, and in the vigour of their intellectual work of imparting and expanding those sciences, were placed on the board or "court" of examiners—teachers would be stimulated to prepare their pupils to be tested in relation to more advanced conditions of those sciences, than there is any call for under the present state of the "pass-examinations".

The obstacles to such improvement in the examining board may be exemplified in the conditions of its existence at the Royal College of Surgeons of England. The administrative authorities of that College are concerned, both in purse and dignity, in themselves performing the work of examination. In purse, by the way and degree in which they remunerate themselves for such work; in dignity, because no member of the Council is eligible to the offices of vice-president and president of the College until he has been an examiner. As such, his remuneration being in the ratio of the number of persons examined, must now be of material importance.* Accordingly, the Council, twenty-four in number, elect out of their

own body ten to be examiners, reserving to themselves the testing in all the required sciences and subjects, save midwifery, dentistry, and classics.

I note this, therefore, as one of the impediments to the progress of medicine and surgery as sciences: an evil which will be abated in proportion as those to whom the profession confide administrative power may approach in singleness of purpose and motive to the administrative bodies of our universities, in regard to the business of examination for degrees and diplomas.

The Royal Society of Arts has recently given an example which the Royal College of Surgeons would do well to follow. On undertaking responsibilities connected with examinations of candidates, the Council of the Royal Society of Arts at once passed the self-denying ordinance that no member of the Council should be eligible to the post of examiner. Yet the Council always includes men well qualified for the office, but not every man so qualified, and seldom those who are best qualified.

[Professor Owen finally congratulated the students on the choice of their profession; comparing medicine with law, and with divinity as distinguished from religion; pointing out in this comparison the advantages of medicine in the opportunities it gave of acquiring and advancing knowledge of the various forms of the power of the Creator, in the greater freedom allowed in the use of the intellectual instrument, in the exclusively beneficent application of medical science, and the freedom from any calls of its professors to punish or persecute their fellow men.]

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH. At a meeting of this Society held on May 20th, Dr. Druitt in the chair, Mr. Haynes Walton read a paper on "The Contagious Affections of the Eye." He said that by the term used he expressed the communication of ocular disease from one individual to another; and he considered that, while the direct effect of contagion on the eye appeared only in conjunctival affections, more injury and loss of sight was produced from this cause than from any other diseases of the organ. He referred to the prevalence of catarrhal ophthalmia in the Central London District Schools; and recommended the following measures to be employed in all such instances. Absolute separation of the diseased persons from the healthy; classification, if severer cases occurred among the diseased; the institution of a rigid convalescent system of probation, to prevent relapsing cases from doing mischief; a morning and evening inspection of the whole establishment, so that there might be the most timely removal of diseased individuals; the strictest attention to the withdrawal of any known or supposed exciting cause of the diseases; and the adoption of the highest hygienic measures among those under surgical treatment. He then went on to speak of infantile purulent ophthalmia; and, after alluding to its frequent origin from the contact of leucorrhœal discharge and sometimes from gonorrhœal matter or other sources, he strongly advocated the necessity of early treatment of the eyes of infants thus affected. They should be cleansed early and frequently; and remedies, when required, should be applied without delay. He concluded with some remarks on granular conjunctiva, speaking of it as a frequent source of contagion, even when, from the absence of purulent secretion, it might be supposed that no danger of contamination existed. After the reading of the paper, a discussion followed, which was shared in by the President, Dr. Mapother of Dublin, Mr. Liddell, and Dr. Rendle.

* In the year 1817, the Council determined by bye-law, sect. xxii, that "Every member of the Court of Examiners, who shall be present at the opening of any stated Court of Examiners, shall be entitled to half-a-guinea; every member, who shall be present at the adjournment thereof, shall also be entitled to half-a-guinea. And, for every examination for the diploma, the examiners, who shall have been present from the commencement until the termination thereof, shall be entitled to the division of nine guineas, whether the person examined be approved or referred."

HOSPITAL PRACTICE:

METROPOLITAN AND PROVINCIAL.

BIRMINGHAM GENERAL HOSPITAL.

TREPHINING FOR THE RELIEF OF EPILEPTIFORM
ATTACKS, OCCURRING AFTER INJURY
TO THE HEAD.

By JAMES RUSSELL, M.D., Physician to the
Hospital.

THE case which has suggested the following remarks, and will be detailed presently, was under the joint care of my colleague, Mr. Bolton, and myself; it was one in which fits, in all respects resembling true epilepsy, came on five years after a blow inflicted upon the head with a pointed instrument. At the time of the patient's admission into the hospital, the fits were increasing in frequency, and the mind was rapidly deteriorating; trephining was therefore performed as a last resource. A bunch of short spicula, represented in fig. 2 of the

Fig. 1.—External view; shewing depression of skull.

Fig. 2.—Internal view; shewing spicula.

accompanying sketch, for which I am indebted to my friend, Mr. C. J. Bracey, projected from the interior of the skull. The patient died of acute meningitis.

I have examined the records of as many cases of a similar description as were accessible to me, with reference especially to the success of operative proceedings; first, as regards immediate recovery from trephining; secondly, as respects the removal of the disease for the relief of which the operation was undertaken; and I propose to state the result in the course of this paper.

Convulsive movement of different degrees of severity, and involving various extent of the body, are among the nervous phenomena liable to ensue after injuries to the head, happening sometimes among the primary, sometimes among the secondary consequences; being either the direct effect of the injury, or occurring at various periods afterwards. Of this latter class of cases of convulsions, a certain proportion result from inflammatory change; but many, constituting the group to which this paper has special reference, are the result of a perverted state of innervation, gradually engendered as a more or less remote result of the injury experienced, or induced, as in my present case, by continued irritation operating upon the membranes or upon the superficial tissue of the brain. In what I have further to say upon the subject, I desire to be understood as excluding altogether the convulsions which may attend inflammation or active cerebral disease induced by the injury.

The convulsive attacks after injury to the head

may be general and severe, affecting the entire body; or, as is more generally the case, they may be comparatively slight and partial, consisting merely of convulsive twitches, affecting, it may be, the upper limbs alone; or, again, they may present that peculiar sequence of phenomena, and that purely paroxysmal character which we usually associate with the idea of epilepsy. This latter class of convulsions, the epileptiform, viewed symptomatically, stands distinguished from the former by the union of sudden insensibility with the convulsion, implying thereby that an additional set of nerves is involved in the convulsive effort; viz., the vaso-motor nerves supplied to the blood-vessels of the brain.

It is stated, however, by some excellent observers, that in this form of paroxysmal convulsion, when occasioned by injury to the cranium or by disease connected with the brain itself, coma is often entirely absent. Such has been the case in some of the instances which will be referred to in the following remarks; but in the majority, it is either announced directly, or is left to be inferred, that consciousness was lost. It need hardly be added, that no specific pathological difference can at present be established by the presence or absence of coma, nor between the class of epileptiform convulsions and other forms; though it is important for our present subject to add, that the convulsive attacks with which I am at present concerned as requiring the operation of the trephine, generally approach more or less exactly to the type of true epilepsy.

In my present case, from the small size of the spicula which projected from the skull, it is probable that the irritation which caused the fits was applied directly to the membranes—at least, without wounding the substance of the brain. In this particular, the case resembles many others on record, in which the cause of the nervous phenomena seems to have operated primarily on the membranes, and consisted merely of thickening and roughening of a portion of the cranium, the membranes being alone involved in the direct irritation which resulted; but in many other examples the matter of the convulsions itself suffers irritation through the entrance into the substance of the brain of spicula after injury, or through the presence of outgrowths from the inner surface of the skull indenting the cerebral tissue; or, again, in a small number of cases, by a recent or ancient coagulum lying upon the surface of the hemispheres.

An interesting observation by Dr. Marshall Hall (*Med.-Chir. Trans.* xxiv, 122) illustrates those cases of convulsions in which the membranes alone are primarily concerned. He says: "In one important experiment.... I found that, although every kind of irritation, puncture, laceration, etc., of the cerebrum and cerebellum was entirely inoperative, yet laceration or pinching of the dura mater immediately induced peculiar spasmodic movements of the eyeballs, the eyelids, the head, etc." Dr. Hall refers the phenomena to the trifacial nerve, which, "as in the recurrent of Arnold, is well known to impart branches to the dura mater, and which may do so to the other membranes within the cranium." This liability of the membranes to take on morbid action of a purely nervous character affords a parallel to the well known tendency of the same tissues to assume inflammatory action when involved in any injury, thereby constituting an important source of danger in compound or depressed fractures of the skull. Thus, in speaking of the danger of inflammation after injuries to the head involving the brain and its membranes, Mr. Bryant (*Guy's Hospital Reports*, 1859, p. 49) pointedly observes "how powerfully nature resents any scratch or injury to the dura mater."

As regards the production of convulsions by direct

injury to the substance of the brain itself, it is most probable that, in a large proportion of instances, including all those in which the injury is inflicted upon the hemispheric lobes, the mechanism by which the movements are effected involves precisely the same principle as in the case of the membranes. It would appear that the convulsive centres, the portions of the brain which, when irritated, *directly* give rise to convulsive action, are quite separate from the hemispheric portion, and are probably connected with the mesocephale and the medulla oblongata. Such appears to be the opinion of Schröder van der Kolk, founded upon his own observations and upon those of Pfleger, in a passage to be quoted presently; and to the same effect is a remark by Kussmaul and Tenner, quoted by Dr. H. Jones (*Functional Nervous Disorders*, p. 56), that in cerebral anæmia epileptic convulsions only manifest themselves in man, when, together with the cerebrum, some or all parts of the encephalic mass lying behind the thalami optici are suddenly deprived of blood to a sufficient amount. Hence, when convulsive movements result from irritation applied to the hemispheres of the cerebrum, the convulsions are produced by reflex action; the irritation being conveyed by the white substance to the convulsive centres.

Thus, Dr. Todd (*Lumleian Lectures*, 1849) observes that "it is not the office of these fibres (of the cerebral hemispheres) to propagate the nervous force to muscles, but to other nervous centres. Their function is to establish communications between the great sheet of vesicular or grey matter which covers the convolutions of the brain, and the corpora striata, optic thalami, and mesocephale; so that changes in any of these centres may be propagated from any one to any other or to all the rest." Hence, he concludes, that "we must not deny to these lobes (the hemispheres) a certain power of exciting motion, either directly or indirectly through their influence, upon other ganglia of the brain." He then relates certain experiments of his own, which confirm the conclusion formed by other observers, that convulsive action is produced *directly* only by irritating those portions of the cerebral mass seated at the base, which I have already named; viz., the medulla oblongata, the mesocephale, and the corpora quadrigemina.

One observation made by Dr. Todd in this connection is nearly related to the subject of this paper; that the power possessed by the hemispheres of the brain to excite convulsions through reflex action is most manifest when the lesion of the brain is superficial—i.e., when it affects the grey matter of the convolutions. This statement is brought into still closer connection with the nervous derangement produced by injuries to the skull, by the result of Dr. Bright's experience in epileptiform disease (*Med. Rep.* ii, part ii), which is to the effect that cases of epilepsy connected immediately with organic changes in the brain, more frequently depend on disease affecting the surface than on such as is deeply seated; and, subsequently, in summing up his cases of epileptiform diseases, he observes that, of eleven cases in which there was evidence of a direct morbid condition of the brain or its membranes, or of the skull, in none had the organic disease extended into the medullary substance, and in most it had penetrated little deeper than the membranes themselves.

Fits of convulsions, in all respects resembling a fit of epilepsy, may occur during the process of reaction after concussion; but those which happen among the primary consequences of injury to the skull, are regarded by Sir B. Brodie (*Med.-Chir. Trans.*, vol. xiv, p. 367; and Cooper's *Surg. Dict.*) as probably dependent upon direct injury to the sub-

stance of the brain, and not upon compression merely. Sir B. Brodie states that, whenever he has noticed these convulsions as attendant upon depression of the skull or upon extravasated blood, and has afterwards had an opportunity of ascertaining the exact nature of the injury, the pressure has always been found complicated with wound or laceration of the substance of the brain.

This observation of Sir B. Brodie, which is echoed by other authors, receives an interesting illustration from a group of seven cases by Mr. Banner, surgeon to the Liverpool Northern Hospital, related in an able paper contained in the ninth volume of the *Transactions* of our Association. In all the seven cases there was laceration of the substance of the brain. The laceration was extensive in five; but was confined to the substance of the hemispheres in all. In one only were the central ganglia, the corpora striata, or thalami, involved. Convulsive movement was present in all the cases; but the convulsions were violent in one only. They are generally described as convulsive twitchings of the limbs, and occurred in paroxysms, reminding one very much of fits of the milder forms of epilepsy *minus* the coma.

A case which appears to have attracted considerable attention at the time, as it occurred in the person of Lord Brougham's nephew, and was copied into the *Medical Gazette*, vol. x, p. 797—a case of extensive injury to the skull—proves that in a certain peculiar conformation of brain the convulsive action may be most violent; but it has also drawn from Mr. Guthrie the observation that the case is exceptional in this particular, as manifesting convulsive action so general and so violent among the early consequences of this particular injury. It is related in this case that Mr. Crampton had scarcely touched with the forceps a large fragment of bone bedded in the brain, than the whole body was shaken with violent convulsive movements; Mr. Crampton then tried merely to cleanse the wound; but scarcely had three drops of water fallen on the raw surface, than the patient cried out in a voice more expressive of terror than of pain, complaining that the sensation was dreadful. As a consequence, all attempts to extract the bone were abandoned, and the wound was not so much as washed for twenty-two days. Perfect recovery resulted. The great wound healed in two months; but small spicules were discharged for a year. The patient was seen in perfect health six or eight years afterwards.

Convulsive action, however, is far from being a necessary attendant upon laceration of the cerebral hemispheres; and this fact affords confirmation to the opinion expressed by Dr. Todd. How wide, indeed, is the interval between the extreme degrees of sensitiveness to irritation on the part of the brain, is well shewn by a case under the care of Mr. Birkett, quoted by Mr. Bryant in the paper in *Guy's Hospital Reports* already referred to. The patient, a woman, lost seven square inches of skull in consequence of injury, without presenting any serious symptoms during the course of her protracted cure.

From the observations just made, it appears that epileptiform fits produced by injury to the head fall under the category of reflex irritation together with the numerous cases of so-called symptomatic epilepsy resulting from irritation seated in some part of the limbs or trunk; and have a special analogy to the instances in which a foreign body irritating a nerve, a cicatrix producing a like effect, or a tumour situated upon a nervous trunk, proves the exciting cause of the fits. It would also appear that much the same may be said, with certain limitations, of the other forms of convulsions which occur after laceration of

the brain. There are, however, certain specialities connected with a large number of those epileptiform attacks more particularly referred to in this communication, which impart to them a distinctive peculiarity. They often do not occur until a certain interval of days, even of months, has elapsed from the receipt of the injury (in the case which has suggested the present remarks five years had intervened); but when once established, they generally continue to recur, in separate paroxysms, perhaps through the whole remainder of the patient's life—it may be even after the cause of the irritation has been taken away by operation. The convulsive movements are also more severe and general than is often the case under the other circumstances; and, in course of time, they may be attended by deterioration of the health of the brain. The irritation by which the convulsions are excited in such cases appears often unequal to produce an immediate effect; but, being permanent in its operation, exerts a reflex influence upon the nervous centres, by which, in process of time, some nutritive change is effected in those centres, disposing them at last to take on disordered action. Hence the tendency in the disease to permanence; and hence we may perceive a source of uncertainty as to the final success of the operation of trephining—an uncertainty which becomes greater in proportion to the length of the period of incubation of the fits, in proportion also to the duration of the subsequent disease. Of course, the same remarks apply equally to the epilepsy which is occasioned by organic disease of the brain.

I may note, in passing, that if these remarks be founded on fact, they exclude the cases of what have been termed centric epilepsy from constituting a distinct class, and associate them closely with those in which the irritation starts from some other region of the body. In truth, it would appear that centric epilepsy, if existing at all as a distinct form of disease, should rather refer to those numerous cases of the malady, chiefly observed in young persons, in which the attacks develop themselves without apparent cause, in consequence of congenital tendency or of nutritive changes effected in the nervous centres, either in the few first years of life or at the period of puberty. They also suggest certain difficulties as to recent suggestions on the subject of the application of the term epilepsy, to which I may take a future opportunity of referring.

Among the cases of epileptiform disease induced by injury to the head, there are, however, not a few which differ somewhat from the class of which my present case is a type, but, from the interest which attaches to them, require separate notice. I refer to those cases in which the consequences of the injury are limited entirely to changes in the tissue of the skull, without any depression or fracture having occurred. The records of cases in which trephining has been performed for the relief of nervous disorder, afford many instances in which the lesion of the bone has consisted in change of structure gradually induced; such alteration of structure being still connected with the nervous symptoms, by the success which has attended the operation. Thus, the following alterations may be noted as having been present under such circumstances: extensive osteitis, with great thickening of the bone and the presence of points or granulations on its inner surface; more or less thickening and induration of the bone, without any outgrowth; exfoliation of the bone, confined to the outer table, or penetrating through its entire thickness; complete perforation of the three tables by openings of different diameters, probably from previously existing caries, the surrounding portion of bone being healthy, or thickened, spongy, and

vascular; disease of the nature of caries confined to the inner table of the skull.

An interesting case of this character is detailed in the *London Medical and Physical Journal*, 1855, p. 103, in which urgent nervous symptoms, including hemiplegia, and followed by paroxysms of epileptiform convulsions, presented themselves after a blow with a fist, severe pain remaining in the part. From the moment the circle of bone was removed by the trephine, the paroxysms of convulsion became considerably mitigated, and ceased altogether in the course of a few hours. The hemiplegia was removed in a month. The trephined portion of skull was found to be very thick.

A similar case is quoted by Mr. Guthrie (*Injuries to the Head*, 1842, p. 80). A more remarkable example is afforded by a case reported in the *Medical Gazette*, vol. xvii, p. 221, probably of syphilitic origin. Severe fixed pain, and subsequently epileptic convulsions, occurred. Both were temporarily relieved by incisions made over the affected part; and, also, by entire removal of a portion of the covering integument, and by seton; each measure being employed separately; but they returned in every instance. Temporary hemiplegia then occurred; and, finally, the increasing urgency of the symptoms, especially of the convulsions, rendered trephining necessary. A considerable portion of greatly hypertrophied bone, more than twice the normal thickness, was removed with perfect relief to the symptoms.

Natural analogy carries us on from these cases to others, in which the bone is spared, and the morbid action excited by the injury is limited to the perosteum; and from these, again, the transition is not difficult to other cases of a singular character, many of which have been reported, wherein the change, whatever it was, seems to have been entirely confined to the integuments of a particular part of the scalp, the seat of the blow which originated the disease. The existence of an abnormal condition in this particular spot is evidenced by severe persistent pain, and sometimes by extreme sensitiveness—touching the part causing exquisite pain, and often paroxysms of serious disorder, especially of insensibility or convulsion; or, again, by a well marked aura starting from the same place. In some cases, the abnormality has also been declared by alteration of external appearance.

Dr. Abercrombie has specially drawn attention to these cases in the appendix to Part I of his well known work, under the title of Certain Affections of the Pericranium, founding his remarks more immediately upon reports by Sir E. Home and Mr. Cramp-ton. In many cases, the symptoms were removed by free incision through the affected part, and the encouragement of free suppuration; in some, by keeping the wound open by the insertion of issue-peas. Other cases of a similar kind are mentioned by John Bell (*Surgery*, vol. ii, p. 303). In many of these cases, the disease lay manifestly in the pericranium, which had been inflamed and become thickened; and in some the bone was finally involved; but in others it appears to have consisted in some change either of nutrition or of innervation, remarkably limited to a particular portion of the cranial integument.

In one instance quoted from Pouteau by Dr. Abercrombie, intense headache, often causing insensibility, persisted in the spot for sixteen years; the integuments being slightly red and a little swollen, and the hair in the affected part being coarse and standing out like bristles. Complete success followed incision. In the *Medical Gazette* (vol. xxxiii, p. 379) is detailed a case in which insensibility and convulsion ensued almost immediately on the receipt of a blow of no great severity. The symptoms, which

were violent, remitted in a few days, but returned in eight months. Free incision through the tender spot, the wound being kept open with peas, effected complete cure.

More recently (*Medical Times and Gazette*, 1862, ii, p. 43), Mr. Downie has related a somewhat similar case, convulsive fits setting in six months after a fall which produced concussion. Here the reflex irritation appeared to be propagated through the branches of the fifth pair. The symptoms were removed by local medication.

The analogy which exists between these cases and others in which the irritation starts from a remote part of the body or limbs, is completed by an example in the *Dictionnaire des Sciences Médicales, Epilepsie*, p. 518, in which epileptic fits repeatedly ceased after a cicatrix on the scalp had been opened by caustic, but returned as often as it was permitted to heal.

There can be little doubt that, in many cases of this description, a highly abnormal condition of the nervous system generally, or of the nerves of the particular part, had existed previously. This is to be inferred from the extremely slight cause stated by Dr. Abercrombie to be able sometimes to produce such serious consequences; as, *e. g.*, the fall of a small piece of plaster upon the head. But there is reason also to believe that, in some instances, the diseased action had extended from the superficial parts to the membranes of the brain. Thus, in a case by Mr. Crampton (*Dublin Hospital Reports*, i, 343), considerable thickening of the pericranium, resulting from a blow received six months previously, was accompanied by severe local pain, wasting paralysis of one arm with rigidity, feebleness of both lower extremities, indistinct speech, and epileptiform attacks. On operating, the bone beneath was found carious, and the dura mater was very vascular and rather thickened; it sloughed in the course of the cure. Perfect recovery was effected in a fortnight, even of the paralytic symptoms.

It is necessary that I should add, for the complete elucidation of this part of my subject, that epileptiform attacks are by no means the only symptoms which may result, independently of the effects usually referred to compression of the brain, from the injuries or other affections which have formed the subject of the preceding remarks, as will have been observed in some of the cases already quoted, particularly in the last. Thus not only severe fixed pain, but hemiplegia, apoplecticiform attacks, vertigo, defective vision, incoherence, delirium, mania, have been mentioned by authors, and especially by Mr. Guthrie, as occurring after injury to the cranium; and, in the instance of the convulsive affections themselves, other symptoms are often superadded, such as mental excitement, muscular paralysis, impairment of special sense. In many such cases, we obtain clear evidence of a reflex origin of the symptoms, by their being removed through the same agency which relieves the convulsions when they are present.

Thus Sir A. Cooper (*Lectures*, i, 309) mentions a patient who became quite insane and hemiplegic after injury to the head. A depressed portion of bone was removed by the trephine; the insanity was much relieved on the following day; the hemiplegia was gone in a fortnight. A still more striking illustration is afforded by Mr. Guthrie (page 84), in which a heavy blow on the head was followed by fixed pain in the part struck, and by impaired power in the opposite arm, ending, in eleven months, in complete left hemiplegia, and in impairment of vision, hearing, and memory. The patient was trephined; the bone was quite healthy; and nothing occurred in con-

nexion with the operation which could promise an alteration in the condition of the patient, except free bleeding from the vessels of the diploe. Nevertheless, she raised the previously paralysed arm several inches an hour after the operation; and sensation had returned to it. The paralysis and the affection of the senses had quite gone in three days.*

[To be continued.]

Original Communications.

ON VITAL FORCES:

THEIR PHYSIOLOGICAL AND PATHOLOGICAL APPLICATIONS.

By JAMES RHODES, Esq., Glossop.

In a previous paper, inserted in the *BRITISH MEDICAL JOURNAL* for February 4th, 1865, I ventured to bring forward certain views on the origin of nerve or vital forces. Since then I have read with pleasure the opinions of Dr. Richardson, which he kindly pointed out in the number of this *JOURNAL* for February 25th, 1865. Our opinions are to some extent alike; yet, as we proceed, it will appear that some difference exists.

Physiologists have, with a few exceptions, hitherto considered the nerve-centres to be the true origin whence the forces or energies of the system are derived. I beg to direct attention to Dr. Richardson's "Physics of Disease" for January 7th, 1865, and to what I have already stated; and consider it necessary to introduce a few more facts which will help to convince any who cling to the old creed of the truth of our opinions.

In addition to the experiment of Grove before quoted, I think the following facts, which I here introduce, will prove the unity of forces. If we take three equal pieces of zinc, we may obtain light and heat from one piece; heat alone from the second piece; and electricity, with some heat, from the third piece. Again, the different forces thus produced from the same equivalent pieces of zinc, acted upon by oxidation, would, if collected, be equivalent one with the other; neither more nor less.

I submit that the process is alike in all three instances, and produced by oxidation. A piece of sheet-zinc will give out a bright light when burnt in a current of oxygen, or in a bright fire by blowing it; another piece, acted upon by dilute sulphuric acid, will give out considerable heat; whereas, when another piece is acted upon by diluted sulphuric acid, and connected with a copper plate or carburetted iron bar with its nitric acid bath, each of these provided with copper wires, and connected, in fact, to make a battery,—the force in this case is converted into electricity, which can be again disposed of at pleasure into simple motion, heat, and light, by varying the conditions.

With these important facts before us, we are prepared to understand the vital processes. These facts, by comparison, indicate strongly that afferent nerve-force is not generated from heat, any more than electricity is generated from heat; but that it is generated from that which, under other conditions, would generate heat.

Although the exact conditions for the generation of nerve-force in the living apparatus are not present

* My present case may be adduced as a further example; hemiplegia occurred in the course of the meningeal inflammation, the corpus striatum and thalamus being found perfectly healthy after death by microscopic examination.

as in a galvanic battery, still we have what amounts to the same thing—the same results by oxidation. By experiment we produce, from the same source, heat and electricity, just as heat and nerve-force are generated in the capillaries of the system and brain. Ganglionic nerve-fibre, and cells, accompany these minute vessels; and the oxidation of the carbon and hydrogen of fatty matters, and of albumen into fibrine, effected in contact with the walls of these vessels and the nerve-fibres, eliminates this nerve-force, to be conducted to the nerve-centres and ganglia.

Let us return to C. Bernard's experiment showing the "calorific" effect of section of the sympathetic. He considered the increased temperature to be owing to some specific action effected by the nerve when divided; but how produced he has not stated. Is it supposed that heat issues from the divided nerve? If so, the heat would be greatest at the divided part; but it is not so; the temperature of the limb is uniformly increased.

I do not intend to follow this force to the seat of volition or consciousness, or to enter upon the subject of paralysis; yet the remarks here presented seem to offer an explanation of some of the phenomena in lesions of the nerve-centres. I may be excused the suggestion, that when any of this force or energy is required in involuntary acts of the system—as, for instance, vaso-motor function, the action of the heart, etc.—the nerve-force is simply conveyed to the ganglia, and, without any change being effected there, returns by efferent nerve-fibre to these parts, to produce motor effects. From the free communication which takes place in ganglia and nerve-centres between the nerve-fibres and cells, we may readily understand how the "sympathy" of one part with another is effected through increase or decrease of current and conducting power of nerve. Dr. L. Beale thus speaks upon this subject; and, as his opinion closely approaches Dr. Richardson's and mine, a brief allusion will be given.

"It may now be nearly regarded as proven that the nerve-fibres do not terminate in the parts to which they are distributed, but, after travelling from some particular centre to an extremity, then take a backward course, and finally arrive at the point from which they started. Admitting this view, we then have another fact in support of the hypothesis that nerve-force, as it is called, is nothing more than electricity acting under peculiar conditions. Dr. Beale, though he by no means claims for this doctrine an universal assent, still conceives it to be at least probable. In speaking of the two sets of cells, *caudate* and *rounded*, which are connected with the nervous filaments, he attributes to the latter the power of originating currents, while the other is concerned more particularly with the distribution of these, and of secondary currents induced by them, in very many different directions. A current, originating in a *ganglion-cell*, would possibly give rise to many induced currents as it traversed a *caudate nerve-cell*. It seems probable that nerve-currents, emanating from the rounded ganglion-cells, may be constantly traversing the innumerable circuits in every part of the nervous system; and that nervous actions are due to a disturbance, perhaps a variation in the intensity of the currents, which must irremediably result from the slightest change occurring in any part of the nerve-fibre, as well as from any physical or chemical alteration taking place in the nerve-centres, or in any of the peripheral nervous organs."

How Dr. Beale accounts for the origin of nerve-force from the rounded ganglionic cells themselves, I cannot see. It cannot originate of itself; nor can the cells generate force; this alone must come from

something which has previously existed as motion or force in some form or other, and thus become appropriated through nerve-ganglia, cells, and fibre, for the requirements of the system. Dr. Richardson conceived the idea of the origin of the energies of the system from the oxidation of carbon, etc., acting upon nerve-fibre, wherever found. We agree together so far as the origination of nerve-energies in the capillaries by oxidation; and it is here our views differ. M. C. Bernard has given one experiment which proves that nerve-force is not generated at the peripheral extremity of sensitive nerves of the cerebro-spinal system, but rather that the nerves of this system receive their force or energy from the sympathetic nerve-cells at their periphery.

"Having opened the spinal canal in dogs, he divided, as they left the chord, all the origins of the sacro-lumbar plexus (sometimes on one side, and then the other), which supplies sensation and motion to the hinder extremity. The limb became completely paralysed, but no calorification or vascularisation was observed; the temperature on this side often, indeed, diminishing. When only the posterior and anterior roots were divided, corresponding abolition of sensation or of motion occurred; but in neither case were there any vascular or caloric effects in the limb. In a dog, in which complete paralysis of the left hind leg was produced by division of the origins of the sacro-lumbar plexus, the *sciatic nerve* (and thus the sympathetic) was afterwards divided. Vascular and caloric phenomena immediately followed; the temperature of the limb steadily rising until it was from 11° to 15° Fahr. higher than that of the opposite one, and so continued until the death of the animal the next day."

It is obvious from this experiment that, if nerve-force originated at the periphery of the nerves of the cerebro-spinal system, we should have "calorific" effects when these nerves are divided at their roots since the current to the centres would be arrested, and, instead of a nerve-current, increased heat would be generated in the limb, as occurs when the sympathetic is divided. Therefore we can readily understand how nerve-force generated by oxidation in the capillaries takes two courses; one—the chief—along the sympathetic nerve-fibre to ganglia, and thence to nerve-centres; the other through a connexion with ganglionic cells with the peripheral extremities of sensitive nerves—all nerves of sense—in such amount as is necessary to supply these with their special functions. It therefore follows that increased temperature of the limb in this experiment does not take place as where the sympathetic is divided; for the nerve-force, which is prevented passing along the divided sensitive nerve, will pass along the undivided sympathetic nerve-fibre, together with the rest.

It is not necessary to discuss the question whether nerve-energy is generated at the peripheral extremity of motor nerves, since these receive their energy from the nerve-centres. In addition to what I have stated in the BRITISH MEDICAL JOURNAL for February 4th, I beg to refer to three cases of embolism of the arteria centralis retinae, recorded in the *Ophthalmic Review*. At page 113, Dr. Liebreich says he has met with eight cases of this affection, and gives notes of an interesting case of loss of vision by this means. Two cases will be found at pages 163 and 196. The loss of vision comes on suddenly, and there accompanies them dilatation of the left ventricle, with diastolic *bruit*. Von Gräfe gave the first detailed account of these cases; and, a year and a half after the attack, the patient died; and, on a *post mortem* examination, the diagnosis was fully confirmed by finding occlusion of artery. The evidence afforded by these examples of suspended and de-

stroyed function of vision proves indisputably the immediate necessity of the arterial blood supplied to an organ for the performance of its functional activity, be it in the eye or any other part. Here we see blindness coming on; and, if we consider the loss of sensation in a limb when the main artery is ligatured, the two cases are seen to be strictly parallel in result; viz., loss of function or sensation. This effect is not the result of suspended nutrition of the nerve by cutting off the supply of its nutritive fluid, as is proved by the instantaneous effect. It is alone the suspended oxidation which supplies all organic, and, through these, sensitive nerves, at their periphery, with nerve-force. Thus, when heat, light, sound, or any mechanical stimulus, is received by an afferent nerve, force is necessary to convey it to the nervous centre.

Dr. Richardson denies, although I believe, that when "an impression is made upon the skin, eye, ear, etc., this is conveyed in a current to the brain;" he holds "that the impression disturbs the balance of nerve-fluid throughout its universality." Although the picture of an object falling upon the retina is not conveyed along the optic nerve, yet the excitant or stimulus—light—acts upon the different parts of nerve-expanse, and the impression of the picture made upon the retina is conveyed to the brain, and there produces the same pleasurable sensation—in fact, a picture or sensation of one in the brain, just as we perceive pictures in our dreams, of all colours and vividness, when the eyes are closed in sleep, and no impression upon the retina is received.

I have attempted to give an idea how all forces are correlated both in the animate and inanimate world; and the contemplation of the subject inspires one with wonder and reverence—with the simplicity and magnificence of creation. However inclined, the subject is too vast to dwell upon longer. We will endeavour to apply our knowledge of this subject to the phenomena of diseased action in the human system; and, however imperfectly this may be accomplished, my efforts may serve as indications for others more able to effect. As yet there is one matter which has not been alluded to, and which is concerned in the circulation of blood in the capillaries; viz., endosmosis, etc.

"In endosmosis, when one current exceeds the other, the difference is called the endosmotic equivalent; and what is observed out of the body, the same does take place within it. When, for instance, liquids are poured into the intestinal tube, and absorbed by its villousities, no exchange whatever is observed from the villousities, owing to the more rapid current in these. This difference between the phenomena which take place in living animals, and those observed in organic matter, is due to the rapid motion of the fluids contained in the absorbent vessels; the torrent of circulation carries off the liquids which bathe this outer surface, without restoring an equivalent, according to the ordinary laws of endosmosis, because, in the normal state, the flow of blood is continuous. But, if we arrest its progress by placing a ligature on the vessels, the results obtained are strictly similar to those obtained in the endosmometer; the exosmotic current is then produced as usual (albumen and the salts of the blood crude), the fluids being placed in a state of rest. If the motion of the blood be somewhat arrested, by obstruction from pressure or tumefaction (as in inflammation), the endosmotic action is modified, and effusion will take place. When it is accelerated locally, the absorption continues with still greater activity than before. The activity of this function entirely depends, therefore, upon the rate at which the blood passes through the capillaries."

The absorption of the nutritive fluids in the stomach and intestines, and of oxygen in the air-cells of the lungs, is produced chiefly by the motion and free current of blood through the capillaries of these parts. This is called the *endosmotic current*; and from this known fact of the action of fluids in motion, we may suppose the motion of blood along the capillaries and veins produces the absorption of most of the fluids in the body and extremities. We observe the opposite effect, however, when the current of blood in capillaries is greatly arrested; as in inflammations we have *exosmosis*, owing to the expanded state of the capillaries, and the *arrested* or *lessened* circulation through them. Hence we have solidification of lung in pneumonia, exudation of tough mucus in bronchitis, fibrinous membrane in croup, diarrhoea in enteritis, plastic fibrine in peritonitis and pleuritis, etc. These effusions are increased by too depressing treatment and abstinence from food, especially late on in the disease. M. Bernard has shown that, when the sympathetic in the neck is divided, and the animal well fed, all goes on well, except the increased heat and vascularisation; but, when it is poorly fed, purulent formations are the result in the parts supplied by the nerve on that side. M. Cl. Bernard says: "When the cervico-cephalic branch of the sympathetic has been cut, the conjunctiva, the pituitary membranes, and other mucous surfaces, enter at once into suppuration, when the animal is momentarily deprived of food; so, when the splanchnic nerves are divided, the internal organs of the chest and abdomen suffer in like manner." This result will be owing to weakened action of the heart and defective nutrition; hence diminished endosmosis of oxygen in the lungs from weakened blood-current; and, from the same cause, the formation and deposition of pus will be increased. In cases where this tendency was remote, under favourable conditions, as by lowering the heart's action or depressing treatment, this result would be fulfilled.

We will here consider the leading phenomena of inflammatory action. On what do the heat, redness, and swelling of inflammation depend? There can be no doubt that the organic nerve of a part inflamed has received some lesion, either by mechanical injury, or by depraved nutrition of the nerve affecting its conducting powers to and from its centre or ganglion. In fevers and idiopathic inflammations, it is very probable the whole of the organic system has been undergoing some changes prior to the advent of the disease or the unequivocal symptoms, and which being influenced by meteorological and other influences, the body has been prepared for any further cause which we are inclined to attribute as the sole cause of the disease. Here we perceive three conditions, which, by their presence or absence, preserve health or produce diseased action: 1. Healthy and well prepared material or blood; 2. Proper oxygenation (producing heat and nerve-force), and the due conducting or healthy condition of organic nerves; 3. The free and full action of the heart. The first of these general causes comprehends to some extent those causes which lead to defective nutrition of nerve; viz., good digestion of food, pure air and exercise, with buoyancy of spirit or mind. The effects are the same as occur when the sympathetic has been divided in the neck; viz., dilatation of the vessels, heat, excited sensibility, redness and effusion of various kinds, according to the part or organ affected. In the second condition, the transmission of nerve-force being stopped along the organic nerves, we have increased sensibility, partly owing to the excitant or irritant nature of effused products, but chiefly to the increased temperature of the part inflamed. It has before been shown that this

increased heat is wasted nerve-force, so to speak; or what ought and would be nerve-force, if the nerves possessed their healthy conducting quality. Hence the absence of vaso-motor power, and an expanded state of capillaries. The effusion which ensues in a superficial inflammation is analogous to that in all organs: the phenomena which are presented in all depend upon their peculiar functions, and their disturbance. The capillaries most pressed upon by the tumefaction pour out their contents, or exosmosis takes place; others of these, nearer the surface, will be more expanded than natural; hence absorption by the greater current of circulation through these capillaries, or endosmosis. These changes, progressing, lead to the absorption of tissues and the discharge of abscesses.

In passing, it may not be amiss to allude to alcohol. How does it act? It is apparent that saccharine, fatty, and probably alcoholic matters, produce nerve-force as well as heat; whilst albuminous matters supply the structures by which the body is moved—viz., the muscles and connective tissues. Alcohol may act in the *healthy body* upon the inner surface of the heart and capillaries and the nerves of sense as an excitant only, and the chief amount taken into the system be carried away without undergoing combustion; and thus, after serving this end only, will leave the system enfeebled to the extent to which it has called forth its powers. But what concerns the profession to know is, what are its effects in the enfeebled states of the body, or in low states of disease, as in typhoid fevers, etc. It will act here also as an excitant; but I am persuaded that it does more than this; that it is oxidised, since it does not intoxicate even when given in large quantities, but rouses up the energies of life. The mind resumes its wonted calmness and power, when properly administered, to a much greater extent than can be accounted for by its excitant effect; yet the excitant effect in these cases will be greatly diminished here, since the sensibility and power of the system are greatly reduced; hence the marked effect in these cases is from oxidation. And no smell of alcohol is perceived in the breath and urine of such. It would be desirable to examine the tissues of the body and brain where it has been largely given in these low states of body, to settle this vexed question.

M. Cl. Bernard has shown that, after section of the sympathetic nerve, the blood contains a larger amount of fibrine than usual, and is more easily coagulated, as in ordinary inflammation. This teaches us that, after the relief of congestion of a part or organ by local or general depletion, we may in many cases prevent the too great effusion of fibrine by the cautious use of alcohol; for it is evident that the oxidation of alcohol will, so far as it becomes oxidised, prevent the oxidation of albumen into fibrine; for that which will unite with alcohol would otherwise unite with albuminous matters. Again, alcohol will, according to Dr. L. Beale, produce an excitant or contracting effect upon the capillaries, and thus reduce effusions by keeping down tension. The good effects of alcohol, however, are seen in low cases of fever, and inflammations attending these, in which no fibrine is effused, and also where little of fibrine exists in the blood of these cases. Here we perceive the mind rouses up from lethargy; or, if rambling, it becomes calm and conscious; the pulse becomes full and steady; and a marked improvement takes place, from the heat and nerve-force which it is capable of giving to the system by oxidation. By its excitant action upon the heart, the blood will flow through the capillaries of the lungs with more vigour, and thus produce (by endosmotic current) a greater amount of

oxygen. It may not be amiss to point out the heat capable of being produced by the heart's action.

The amount of mechanical work performed by the heart has been computed by the Rev. Samuel Haughton, M.D., etc., to be equal to 124 foot-tons per day. A near approximation of this may be arrived at by considering the height to which the column of blood is sent from the aorta, and its weight. From the above, we may consider the left ventricle expends force equal to 100 foot-tons per day, at least. This, reduced to pounds, is 224,000 foot-pounds, which, divided by 772, the mechanical equivalent for heat (for 772 foot-pounds equal the amount of heat necessary to raise one pound of water 1° Fahr.), there will be produced about 289° as the quotient—an amount of heat which, divided by 145, the average weight in pounds of a man's body, will give the actual amount of heat which is capable of being produced by the arrest of mechanical force of 100 foot-tons per day; viz., 2° Fahr. for each pound of matter which constitutes the body. When we come to consider this amount divided over the space of twenty-four hours, we shall see how inappreciable this would be at any one of the twenty-four hours; for the heat generated by this means would be inapplicable to us. But we are not certain that all this force is converted into heat. Part is, no doubt, converted into frictional electricity, if we may use the term; owing to the heterogeneous nature of the blood and the coats of the vessels. Friction of homogeneous bodies produces heat alone; of heterogeneous bodies, heat and electricity.

The application of the facts here contained, and their relations in diseased actions, are almost universal. One symptom observable in mechanical injury of the spinal cord is great elevation of temperature in one or both of the lower extremities, owing to injury of the sympathetic, and the arrest of nerve-force to the centres; and hence the same effects as when this nerve is divided in experiments. As Dr. Brown-Séquard has lately said in a lecture, "the circulation in these cases is not more rapid, but fuller and (more energetic)?", than in the corresponding limb. Hence the heated condition of the blood and limb could not be greater than in the other or healthy limb; for, although the arteries may be more expanded on the injured side, from the deficient power of vaso-motor nerves which cause contraction of these vessels, there cannot be more—probably less—of the heart's force arrested and converted into heat.

It will be evident that "determination of blood" to a locality or organ cannot exist, but that it depends upon lesion, disease, or malnutrition of the vaso-motor nerves, which allows the capillaries to become congested and inflammation to result. The importance of this question and of allied conditions known to exist in the phthisical constitution, will enable us to understand the deposition of tubercle in the lungs, etc., and heat in the axillary region.

NOTES ON HERNIA.

By JOHN THOMPSON, M.D., F.R.C.S., Bideford.

[Concluded from page 371.]

THE necessity for care in the after-treatment of cases of herniotomy is amply shown by clinical observation. After bringing the edges of the wound together, and retaining them in apposition by sutures and plaster, a difficulty may arise in keeping the intestine quietly reduced. Where a hernia has had for its immediate cause some violent but temporary muscular effort, the call for which passed at the time, there will be no further unnatural compression of the

viscera after the operation; but, in case the hernia has been produced by severe muscular efforts concerned in coughing or micturition, arising from disease in the system, the circumstances of the case are materially altered, and it will require corresponding increase of attention.

A compress of lint is usually laid over the course of the hernia, and supported by a bandage made to describe the figure of eight in its gyrations over the thigh and pelvis. To such, it is presumed, no exception can be taken. The suggestion is, however, offered, that this simple process should be performed with just the same studied discretion that marks the execution of the cutting operation. Protrusion of the intestine is no imaginary danger; it occurs frequently under favouring circumstances, sometimes merely disturbing the process of healing; but it may be far more serious, and peril the life of the patient.

I was many years ago called to an old woman with strangulated femoral hernia, produced by the coughing of bronchitis, from which she was suffering. Her usual medical attendant met me in consultation; and, reduction being found impracticable, he performed herniotomy in a very neat manner, and to the complete relief of the patient. After this operation, he brought the edges of the wound together with sutures and a few strips of plaster, and supported the whole by a compress of lint and a bandage. On parting, he requested me, as my residence was nearer to the patient than his own, to pay her a visit in case of any urgent necessity; and to this I cordially assented. Two days after, I was sent for in haste; and, on my arrival, they informed me that the patient's bowels were coming out on her thigh; and, indeed, this was about the truth. There was, in fact, a protrusion of intestine which in mass represented the size of a man's fist; it had been forced out between the ligatures, and found its way under the lint and bandage to the surface. Every coughing increased the protrusion, which projected readily through the conical wound, but met with insurmountable obstruction to its return. I was obliged at once to remove the dressings and sutures, and then had no difficulty in replacing the bowels; but the poor patient, who had before been apparently doing well, experienced such a shock that life was as it were snuffed out, and she died in a few hours.

This accident, it may be said, might have been prevented by inserting more sutures, and keeping the parts more firmly supported by the lint and bandage; and probably this is true; but there is a consideration concerned also in the matter of a tight compress.

Some time after this untoward case, I was called to a man with strangulated femoral hernia, produced, as in the former case, by coughing. Here I was the operator. After dividing the stricture and returning the intestine, I inserted a goodly number of sutures, and placed strips of plaster between them as supports; and finished the appliance with two compresses of lint, crossed over the wound, and kept in position by a bandage. This answered very well in preventing protrusion; but, instead of the wound healing nicely, sloughing of the hernial sac took place; and, though the man made a good recovery, it was protracted.

Mr. Erichsen mentions that he has twice witnessed sloughing of the sac, in both instances the patients doing well. He does not suggest the cause of the sloughing, nor will I take the liberty of doing so with his patients; but I have always strongly suspected that, in the instance of my patient, the rather firm compress bore some causative relation to the sloughing sac. Since then, instead of using lint as compress, I have taken a round wad of raw cotton

and placed it along the course of the wound, and bandaged it over. The cotton guards the canal even better than the lint; and, being far more soft and elastic, exercises efficient pressure, with less risk to the infirm tissues surrounding the hernial passage.

Mr. James of Exeter has suggested that the patient should lie on the side opposite to that which has been cut; and the advice appears to be very sensible. This position of the patient would certainly cause the bowels to fall somewhat to the sound side, and moderate tension on the side of the wound.

It has seemed to me correct practice to close the wound completely for the first few days, the period of union by adhesion; and not to allow a communication between the abdominal cavity and the atmosphere. The discharge coming from the wound during the first four days is probably fluid draining from the abdominal cavity, and which there is no necessity for evacuating by the wound, as peritoneal absorption would be quite sufficient for its removal.

Herniotomy sometimes serves as a tapping to the abdomen; and the quantity of fluid gushing out when stricture and sac are both divided may be, as I have known, very considerable. In such cases, effusion has arisen in the abdominal cavity as the result of congestion, or most probably peritoneal inflammation; but that a drain should be left between the abdominal cavity and the surface seems to me even then contrary to modern views of practice, where tapping is resorted to for idiopathic dropsy.

It is most important that the bandage should not be made to compress the abdomen, because it would thus favour protrusion, or might occasion pain, and increase the tendency to peritonitis. But if its course, after passing round the thigh, is along the truss line of the pelvis, it will be just in place, and the patient will feel no inconvenience.

I had occasion, some time since, to operate for femoral hernia on a woman who had passed the middle period of life, and where strangulation had existed six days. After the operation, a friend of mine who was present undertook, at my request, to apply the bandage; and I left it to him. Two hours after the operation, we returned to see our patient, and found her in great distress. She had vomiting of feculent matter, like as before the operation; and said she was in an agony of pain. I was led at once to examine the bandage, and found that it was around the abdomen, above the crest of the ilium, and made unnecessary pressure. We altered the position, and placed it around the pelvis: vomiting ceased, the pain left, and the patient passed a good night. Had we not kept watch, the consequences would, in all probability, have been fatal to recovery. The same case gave evidence of the propriety of using great care in the dieting. The patient was visited by her medical attendant every two or three hours, day and night, for the first sixty-eight hours; and both the quantity and quality of the food were regulated by him. She took opium in full doses at first; after forty-eight hours, had an enema of warm water; next took a dose of castor-oil; and all with excellent effect. She was free from pain or tenderness; had no vomiting; could relish arrowroot, beef-tea, and such sorts of nourishment; and her bowels had acted nicely by the oil and the enema. However, on the fourth day, the female friends thought fit to supplement the patient's allowance with some sherry; and the result was, that vomiting, stercoraceous in character, came on, and the woman's safety seemed perilled. A strict adherence to the former plan of diet set matters right, and there was no other relapse. She is now quite restored, and enjoys vigorous health; but, I believe, mainly owes her recovery to the great care

taken in the management of her case after the operation.

When, notwithstanding every care, death takes place, its most common cause seems to be peritonitis. I have only had the opportunity of getting a *post mortem* examination in two cases, and in each this was the cause of death; which accords with the experience of other observers. It is very curious how much greater evidence of this affection is given in some cases than in others, the part of the membrane involved seeming to influence the amount and the character of the pain. In a few cases of very old people, life has seemed to ebb from the time of the performance of the operation, as if the constitutional shock were overpowering to the system.

As to results, so much depends on the time that has elapsed from the time of the strangulation to the performance of the operation, and also on the age of the patient, that it seems necessary, in order to make statistics reliable, that records of cases should always detail the age of the patient, and the period during which strangulation has existed. A run of good cases will make the experience of an individual operator look very favourable for a time, till an equally unaccountable succession of bad ones depresses his average to perhaps even a low figure. I have operated on five cases in succession, four femoral and one inguinal, recovery taking place in each; and, again, have been concerned in two or three unsuccessful ones in quick succession. Then, in very old people, vitality being very feeble, recovery is hardly to be expected; though in one case an old woman considerably over seventy, to whom I was called, lived for years after the operation.

As it is necessary that a truss should be worn after recovery from the operation for strangulated hernia, it may not be out of place to remark that some considerable difficulty is occasionally found in managing this for old people, who are commonly the subjects of hernia. They very often complain that the spring of the instrument is too powerful in the first instance; and, after a time, find it hardly powerful enough to support the hernia. This feebleness of action is usually caused more by the chemical action of fluids and air on the metal of the instrument, than by loss of elasticity from use. If the springs of all these instruments were japanned, or covered with some material to prevent erosion, it would be an improvement.

BATH AND BRISTOL BRANCH.

FUNGUS HENATODES OF THE EYEBALL.

By FREDERICK MASON, Esq., Bath.

[Read January 25th, 1865.]

H. B., aged 14 months, the child of a farm labourer, a fine well developed infant, was brought to the Eye Infirmary on December 27th, 1864. The child is the youngest of eight, all the others of which are healthy. The parents are healthy; but the child's maternal grandmother is said to have been scrofulous; or, in the mother's words, to have suffered from "evil". The exact character of this disease is doubtful, as some operation was performed for its removal from the face when she was young.

The mother gave the following history. When the child was born, a white spot was observed behind the pupil of the left eye; and five weeks later, the child was discovered to be blind in that eye, vision being perfect in the right. The iris at this time was

of proper colour, and perfect. The disease advanced, and at the end of six months the pupil must have been dilated to an extreme extent (from pressure from behind), for the eye is described as having then been entirely white. The brilliant reflection of light from the bottom of the eye, when it was exposed to the direct rays of the sun, candle, etc., was especially noticed. It now slowly turned red, and abscess appeared to form, the eye appearing larger and more prominent than the other. In three months—that is, when the child was nine months old—the eye burst, and a portion (probably the diseased and opaque lens) fell on the floor. The diseased mass now grew rapidly, frequently bleeding profusely, but continued partially (about half) covered by the lids, until Thursday, December 21st.

Dec. 27th. There was now a large fungus-looking mass protruding from the orbit and tightly encircled by the lids, which had become oedematous. The growth appeared to be sloughing in the centre, and apparently growing and extending at the circumference, and bleeding freely on the slightest touch. The child was restless, sleeping very little, and evidently suffering much pain.

Dec. 29th. The child was placed under the influence of chloroform, and the contents of the orbit were removed. The growth had no attachment, excepting at its entrance into the orbit. The bleeding during the operation was slight, and there was no hæmorrhage afterwards. After the operation, the child slept well, and there was no bad symptom. The eyelids continued much swollen for four or five days; this then subsided, and the child appeared free from pain.

On the 7th, the child was so much improved that, the mother being anxious to return to her family, it was discharged, promising to attend with it as an out-patient.

The disease appears to have commenced during intrauterine life in the optic nerve, probably within the cranium. Where this nerve emerged from the optic foramen, it was greatly enlarged. The disease must then have passed through the eye, implicating the internal structures; and, after escaping by the ulcerated opening of the cornea, involved to a great extent the anterior portion of the sclerotic, a small portion only of which membrane still appears white and shining.

January 17th. The child was brought to the Infirmary, improved in appearance, and free from pain; and the orbit appeared healthy.

[The child did not return to the Infirmary; but six weeks after the operation, the mother wrote, saying, the disease had returned, and was extending rapidly over the face. The child died on April 19th, 1865. A *post mortem* examination could not be obtained.]

CASE OF RHEUMATIC FEVER, FOLLOWED BY PERICARDITIS AND MORTIFICATION OF THE EXTREMITIES.

By W. G. DAVIS, Esq., Heytesbury.

[Read May 18, 1865.]

HENRY FRANCIS, aged 17, a fine young man, an agricultural labourer, of rather spare habit, the youngest of ten living children, capable of carrying (according to his own report) a sack of beans, was attacked with rheumatic fever in the autumn of 1864. Being sent home to his own parish for change and recovery of strength, he came under my care.

I found him fearfully weak, with great difficulty of breathing, etc. I could not define the *bruits* or murmurs about the region of the heart on account of

its tumultuous action. I sent him by rail as soon as I thought him capable of bearing the journey of twenty miles, to the Salisbury Infirmary, where he remained five weeks, and returned home on March 4th, being made out-patient. A week after his return, he took to his bed, suffering considerable pain, more especially in his extremities, great difficulty of breathing, with a quick, weakish, but at this time regular, pulse. Almost immediately, a superficial gangrene of the feet, and legs to within a few inches of the knee-joints, set in, having a livid appearance, accompanied with vesications and extreme coldness of surface. The hands, and forearms, to within an inch or two of the elbow-joints, soon put on the same appearance; and the nose and cheeks were similarly affected, but these looked as if they had been strongly and rudely painted with caustic, and gave the idea that the nose might be rubbed off with the slight touch of a cloth.

The mortification continued to increase. The pain was excessive; the pulse became irregular; but he remained sensible to within two days of his death, which took place on March 27th, 1865.

He was occasionally troubled with hiccough; his water was high coloured, with a red deposit; his stools were very dark.

On the application of warmth, and threatened supply of carded wool, he prayed that cold might be substituted; and said he derived most relief from a lotion containing bichloride of mercury, which was sent for threatened bed-sores.

POST MORTEM EXAMINATION on March 28th, in the presence of my friend Mr. Bleek. On elevating the sternum with the cartilages of the ribs, etc., I found very great difficulty from the extensive adhesions of the pleuræ, the reflected layers of which were glued together with the pericardium; and the pericardium itself, without containing the least secretion, was so intimately connected with the heart, that it was a work of labour to disincarcerate the heart itself. Amid the adhesions there were fibrinous layers which had become partially organised, very like what Dr. Markham has described under the head of "Pathology of Pericarditis", in his second edition of *Diseases of the Heart*, even to the purulent exudations. On examining the heart, we found it hypertrophied with dilatation, with a peculiar yellowness of lining membrane of both auricles and ventricles. The valves were but little thickened; but in the auriculo-ventricular openings of both sides, in the columnæ carneæ, etc., were numerous deposits of a cheesy substance, much like that in the pericardium, though more organised. The lungs were sound. No other parts were examined.

Of course, the examination of arteries going to the gangrenous parts would have been interesting; but when I say that I went to the cottage where the body was lying, with the conviction that I should be refused a *post mortem* examination, from the antipathy of friends, little accommodation, etc., I would ask those attached to hospitals to make some allowance for this imperfect dissection.

[When this case was read, there was a discussion upon it; the majority believing the obstruction of the heart's action quite sufficient cause for the result.

I would merely hint, might it not have been a case of "embolism"—the carrying on with the current of blood of such particles of the cheesy matter I have described by which the small vessels were blocked up? I would call attention to the age of the patient, and the extreme sensitiveness to the touch of the sphacelated parts.]

British Medical Journal.

SATURDAY, JUNE 10TH, 1865.

SYPHILISATION.

PROFESSOR BOECK has been invited to give the Venereal Commission the benefit of his views touching the nature and cure of syphilis. We may, therefore, usefully seize the opportunity of telling our readers once again what syphilisation is. (See *BRITISH MEDICAL JOURNAL*, Jan. 5th, 1861.) We will take our account of it from a work of Professor Boeck, entitled *Recherches sur la Syphilis*, published in Christiania in 1862. The operation is there thus described.

"I take the virus of an indurated chancre, or of a pustule or ulcer artificially produced. I make three inoculations with it on each side of the chest. Three days later, I make three more on each side, taking the matter from the pustules produced by the previous inoculation. I continue the inoculations on the sides in this way every three days until I obtain negative results; then I inoculate the arms, and continue as on the sides until no further pustules are produced. At this stage, I take the virus from another person, and inoculate it on the sides and arms, or on both; and then continue with this new matter as before. When this new matter can no longer be inoculated on the sides or the arms, I inoculate the thighs, and in the same way. I then, with other virus, again inoculate the sides, the arms, and the thighs, until I find the individual is no longer inoculable with any kind of virus."

Professor Boeck prefers, in his first operations, the virus which has already passed through several individuals, as it is less violent, and less likely to produce phagedæna. Then, as the syphilisation proceeds, more virulent virus may be employed. He commences inoculation on the sides, because experience shows that there the effects produced are milder than on the arms or on the thighs, and consequently the cicatrices produced are smaller. Care must be taken not to make the punctures too close to each other, in order to prevent erysipelas, etc. The first three punctures, for example, he makes on the upper part, and the three succeeding punctures on the lower part of the chest. One puncture, it is true, is as good a three, if it be successful. The professor, however, makes the three, because one of the punctures often fails to produce a pustule. The essential point in the operation is the length of time during which the inoculation is continued, and the interval between the inoculations. The number of punctures made is of no consequence. At the end of three days, a pustule yielding good virus is formed. Three days, therefore, are the proper interval. As regards the period of inoculation, Dr. Boeck says that the process must be continued as long as a pustule can be produced in the individual operated on.

Great cleanliness should be observed during the process. The crusts formed on the ulcers should be softened, and the ulcers covered with water fomentations. The ordinary diet may be given, but spirituous drinks and excesses in food should be avoided.

It is found that, in inoculating infants for the cure of hereditary syphilis, the first inoculations generally fail. In such case, Professor Boeck repeats the inoculation every day until the virus takes; and then it is often observed that the whole series of previously made inoculations produce pustules. When once the virus takes, the inoculation is continued every three days, as in adults. But it is often found that in these cases the hereditary syphilis, in syphilisation, does not follow the regular course which it observes in ordinary syphilis. Negative results may follow after a few inoculations, and then positive results again be obtained in the course of a few weeks later.

Professor Boeck warns his readers that the operation of syphilisation requires great care in its performance. Medical men, he says, from time to time publish their experience of syphilisation; but, in most cases, their operations are not syphilisation at all.

"The inoculations have not been carried on until immunity from the action of the virus has been produced. The times and localities of the inoculations have not been duly attended to. The previous mercurial or non-mercurial treatment has not been noted; or mercury has been given during the syphilisation. And then, instead of attributing the failure of the treatment to their own erroneous method of operating, they discard syphilisation as being ineffectual; although my experience shows that there is no remedy which more surely cures a disease than syphilisation cures syphilis."

Professor Boeck, in this large quarto volume—published, by the way, at the expense of the Government—gives a tabular history of some 3,500 cases of syphilis which had been treated in the hospital of Christiania with mercury, etc.; and he deduces, from a comparison of these with cases treated by syphilisation, results greatly in favour of the latter remedy. Thus he tells us that the average duration of treatment of 3,200 persons who were treated with mercury was 125 days; that of the 3,200 cases, 1,036, or 32 per cent., had a recurrence of the disease; that of 316 persons treated without mercury, the duration of the treatment was 101 days; and 82, or 25 per cent. of them, had recurrence of the disease.

Now, since 1854, Professor Boeck has employed no other treatment in constitutional syphilis besides syphilisation—i. e., in those cases where mercury has not been previously given; and the results of his experience are as follows. Of 252 persons thus treated, the mean time of cure was 134 days. Of these, twenty returned to the hospital with recurring symptoms of the disease, and nine of them were again

syphilised; one was thrice syphilised; one was treated with iodine; ten were treated with external remedies only; and three with iodide of potassium. Hence we have about 11 per cent. of cases of relapse. Then we have the results of treatment by *derivation*; and of this treatment we must say a few words. It was suggested, as an objection, that the benefits of syphilisation—its mode of cure—probably depended upon some derivative action induced by the number of ulcerations made on the body, and independently of any specific action. To answer this objection, Dr. Hjort undertook a series of experiments, forming a constant succession of small ulcers on different parts of the body by means of tartar emetic. In this way, 157 syphilitic persons were treated; the mean duration of their treatment was 178 days, and 19 per cent. had recurrence of the disease.

Thus it appears that the comparative statistical value of these different methods of cure of constitutional syphilis stands as follows, according to Professor Boeck. Of cases treated with mercury, 32 per cent. relapse; of cases treated without mercury, 25 per cent. relapse; of cases treated by derivation, 24 per cent. relapse; of cases treated by syphilisation, 11 per cent. relapse.

Really, it is time that a system of cure which promises so much statistically, and which has so long been evidently practised in *bonâ fides* by a man of Professor Boeck's scientific bearing, should receive some fuller consideration at the hands of the profession than it has hitherto done. We might, in reference to this subject, repeat very much the same words we used in this JOURNAL now more than four years ago; only that now those words apply with greater force than they then did.

"Through much evil report and some little encouragement, Professor Boeck still maintains his position as the leading *syphilisateur* of the day. His facts and reasonings have been fiercely attacked; but he still nails his colours to the mast. Dr. Boeck is amazed that men will not use this healing boon. They regard and judge of it, he says, falsely and illogically. Moreover, they will not use it aright; and, from their own consequent failures, absurdly condemn syphilisation. 'I have often,' he says, 'described the right method; but it seems that I must again repeat the *a, b, c* of syphilisation, for people cannot yet spell the alphabet of it.' And he appeals to facts. 'People object, because they cannot understand its mode of action! In modern medicine, facts are always sought for; but, in the case of syphilisation, phrases, and not facts, are what men ask for.' Now, we naturally feel inclined to side with the objections to this treatment; but at the same time we admit that Dr. Boeck's conscientious and carefully performed experiments are worthy of the fullest consideration, and may eventually be corroborated; but he must not be surprised that they should be sifted and canvassed. He must expect men to be very sceptical about a treatment which thus sacrifices both their persons and their pockets. Many patients will think the remedy worse than the disease. To undergo about sixty operations of punc-

tures—i. e., to have three ulcers made every third day for six months on his body—is both a very unpleasant as well as expensive proceeding.”

We then went on to observe as follows.

“Let us, however, be just. We have, as yet, found no specific cure for syphilis—it may be doubted whether we have any cure at all. There are authorities who never give mercury for it; and there are authorities who regard constitutional syphilis as a ‘fe-companion’—as a thing to be discharged by no medicinal agent from its fixed seat in the body. There are authorities who let nature treat the disease. In fact, we have not yet cleared away our own ignorance and wrong-doing in this matter, as in so many others. We ought, therefore, to be very careful in rebuking Dr. Boeck because he has a strong conviction; and in justice are bound to weigh the value of his 300 cases. Let his position be eventually proved correct (and sooner or later its strength or weakness will be made apparent); then, indeed, we shall be driven to say that here, at all events, is a real remedy for syphilis. And then we shall have to see if such a practice is viable—whether the people will put up with it—whether they will consent to carry some 200 or 300 scars on their body as *remanets* of cure.”

THE COLLEGE OF SURGEONS ELECTION.

WE have much pleasure in announcing, that Mr. Charles Hawkins is one of the candidates for the office of Councillor to the Royal College of Surgeons. We speak advisedly when we say, that we believe London could not produce a Fellow who would more faithfully, disinterestedly, and honestly, further the best interests of the College than Mr. Charles Hawkins. Mr. Charles Hawkins's opinions on the subject of College reforms are well known to the profession as well as within the Council, for he has never scrupled to express them openly. His opinions are those liberal ones which Sir B. Brodie tried to enforce upon the Council, and to which he was sacrificed by the Council.* He is pledged by his convictions to the carrying out of the reforms so much needed in Lincoln's-inn Fields; and all who know him, know that he is not one of those who forget in office the promises which they so freely make before they obtain it.

The entrance of Mr. Turner and Mr. Charles Hawkins into the Council would be a sure sign of coming reform. It is impossible that the ignoring of the very spirit of the Charter, under which the Council hold office, will be much longer permitted by the profession. Indeed, the sentiments which are gradually rising within the Council Chamber itself are antagonistic to the false position which the Council and the Court of Examiners at present

occupy in relation to each other and to the important Corporation which they govern.

We have already stated it as our conviction, founded on some years of experience of the passivity of the Council, and of that improper position of temptation in which the Council is placed, that an alteration in the Charter of the College is absolutely necessary to place the College authority on a healthy basis. By the Charter, the Council was enjoined to do certain acts of liberality, but it was not compelled to do them; and as it did not square with its interest to do them, the Council, ignoring the spirit whilst keeping within the letter of the Charter, has left them undone.

Our conviction is, and has long been, that the interests of the College require that the unnatural connection of the Court of Examiners with the Council should cease; that, in fact, the Examiners should not form part, and the most powerful part, of the Council, so as, in fact, to elect themselves into office; that the Examiners should not overshadow and rule the Council, by whom they are nominally elected, and by whom they ought to be governed; that Councillors should not be forced to make themselves agreeable to, and to fall into the obsolete ways of, the Examiners, in order to secure for themselves admission to the high, much sought after, and, in fact, lucrative office of an Examiner.

It is high time that this manifestly most false position of things was put an end to; and it is very clear that this can only be done by separating the Court of Examiners from the Council, by making it impossible for an Examiner to have a seat at the Council, and so to assist in his own election. That this will eventually be done, we have no more doubt than we have that we are penning these lines. The absurdity and contradiction and unfitness of the present state of things are too manifest for the present age. There was nothing worse ever existed in the old close-borough days of our civic corporations. The sooner reform comes, the happier will it be for the peace and well being of the College; and therefore is it that we sincerely advise the Fellows to elect into the Council men like Mr. Turner and Mr. Charles Hawkins, whose presence there will most assuredly hasten the event.

With regard to Mr. C. Hawkins's aptitude to business, we would refer to the excellent manner in which he has performed the delicate duties of Inspector of Anatomy. Our readers may remember that he was appointed to that post at the unanimous request of the London teachers of anatomy; and we might also add that he was lately unanimously appointed treasurer to St. George's Hospital—an honour never before conferred upon a medical man, and bestowed upon him mainly on account of the straightforward and business-like way in which he has acted as a governor of that hospital.

* Sir B. Brodie carried out the spirit of the Charter. He gave up his examinership to make way for younger men. The result was, that at the next election of President of Council, he was passed over—i. e., not elected President; and simply, because he had honourably retired from the Court of Examiners. Had he, like others, disobeyed the spirit of the Charter, and stuck to his examinership, he would undoubtedly have been elected President. This is what we mean by his being sacrificed to his principles.

Mr. Barnard Holt is also in the field as candidate for a Councillorship; and he deserves the full support of the Fellows. He comes forward, as we understand, pledged to the furtherance of liberal measures within the College; pledged, also, to the giving of votes by written papers to country Fellows.

THE LAST NEW THING IN GRATUITOUS MEDICINE.

SOME benevolent gentlemen, it appears, are engaged in establishing hospital wards for the cure of ladies who are able to pay everybody except their doctor. We are glad to find that for once the united voice of the medical press has been brought to bear against the exercise of this last effort of gratuitous medical benevolence. We need not tell our readers how long we have fought against the amazing folly of gratuitous medical services in all its various characters; but now that others are beginning to recognise the folly of the thing, perhaps we may be able to put such a stress upon those practising it as to obtain from them a reason—a justification—of their practice. In regard, therefore, to this last remarkable development of gratuitous medical folly—wards for ladies in a woman's hospital—we should like to ask of those who foment the scheme the grounds on which they justify their act in the face of the profession. Of course, they have their reasons for action; then let them candidly tell us what those reasons are. We denounce the project in the name of the profession, because, in our opinion, first, the profession at large is deeply degraded by gratuitous medical services; and, secondly, because the general practitioner is seriously injured by schemes of this nature. His very clients are taken away from him—the bread taken out of his mouth. And why, and by whom, is all this done? These are the questions which the promoters of such schemes are bound to answer to the profession. These are the questions of which we have so often demanded the answer in these pages; and, in the meantime, are obliged to interpret after our own way of seeing them.

We affirm, that true charity does not demand these personal gifts of gratuitous medical services; that such services are injurious, both to the public at large, to the recipients of them, and, above all, deeply injurious to our own profession; that they do not win for us either the esteem or the gratitude of the public; but rather lower us in public estimation, and so weaken our influence in, and impress on, society at large. We affirm, that charity—the highest Heaven-born gift of humanity—is not the parent of these personal gratuitous labours. We affirm, that real charity begins at home; and that the true virtue—charity towards our own professional brethren—is totally negated by gratuitous medical services.

PROFESSOR BOECK was to give evidence before the Venereal Commission on the 9th instant. We have reason to believe that our northern friend, by his honest and straightforward and unassuming manners, has won for himself the esteem of all with whom he has come into contact. We have no doubt whatever that his appearance in person here will obtain for syphilisation a fair trial in this country. Indeed, it is impossible that the remedy—if such it really be—can longer remain unnoticed in England and in France. Dr. Boeck's scientific and searching labours have placed the matter in such a position as to demand for the subject the consideration of scientific men of medicine. It will be really something approaching to criminal apathy, if some competent member of the profession do not now proceed to Christiania, and study the question in that large field where it is laid open in all its fulness for our consideration. The Venereal Commission would really do a very great work for us, if it would send an unbiassed observer to investigate syphilisation as practised in Christiania. Indeed, we do not see how the Venereal Commission can reasonably report on the special subject of its inquiry—the nature and treatment of venereal diseases—without having previously made itself master of the history of syphilisation. To ignore syphilisation, would be to render their report most incomplete, if not worthless.

OUR readers will be pleased to learn that, at a large and very influential meeting of the College of Physicians on the 6th inst., it was decided (it might be said, almost unanimously) to take action on behalf of our army and navy medical brethren. The existence of grievances suffered by those gentlemen was denied by no one; and on this occasion almost general was the feeling that the College might advantageously interfere in their behalf. The only hesitation felt by the College was as to how it might best move in the matter, in accordance with its own dignity, and to the benefit of the army and navy medical officers. It was eventually decided that the President and Censors should consider the question, and instruct the College as to the most advisable course to pursue in furtherance of the object desired; *i. e.*, whether it should memorialise or petition; and to whom it should address its memorial or petition. The cause of our army and navy medical brethren was warmly and unflinchingly, and we might even say eloquently, sustained by Dr. Owen Rees, Dr. Sieveking, Dr. Meryon, Dr. Jenner, Dr. Brinton, Dr. Gavin Milroy, Dr. Sibson, and Dr. Markham. The opposition was of a very pale and feeble character, and indeed was rather directed to matters of detail than to principle. We sincerely congratulate the College on the wisdom of its action in this matter. We are satisfied that it will thereby do a great service to the country—*i. e.*, to our soldiers and sailors—by assisting in raising the social and professional position of our brethren in the army and navy. That it will gain in the estimation of the whole profession by holding out a generous hand to a class of brethren especially requiring its aid, is self-evident.

THE MARROW OF BONES, IN THE HEALTHY AND MORBID STATES.

In the *Gazette Médicale* of the present year, M. Charles Robin, who has for many years made the medulla of bones the subject of histological investigation, has published the result of his researches. We give an abridged translation.

I.—GENERAL REMARKS ON THE CONSTITUTION OF MARROW.

The medullary tissue of bones is composed of: 1, medullary cells, which are the fundamental element; 2, certain accessory elements called *myeloplaxes*;* 3, a certain quantity of amorphous, homogeneous, semi-transparent substance, which is a second accessory element; 4, capillary vessels; 5, the nerves which accompany the vessels; 6, in certain parts only, fibres of laminar tissue and adipose vessels are found. The presence of these is not constant, and they are not found in all portions of the tissue.

Marrow is found in all the bones of the body; and it extends through the vascular canals as far as the periosteum; so that, on tearing away one of the vessels from a vascular canal, it is seen to be surrounded by a small quantity of marrow, represented by medullary cells, a little amorphous matter, and nearly always some myeloplaxes.

This tissue is also found in the vascular canals of the cartilages of ossification; and has been called the marrow of cartilage. Medullary tissue is even found in the ribs in aged subjects, in whom these organs are hollowed into cavities.

Marrow is remarkably soft, doughy, and in some parts nearly semifluid. But this tissue is not a liquid nor a serosity, as has often been written; its consistence varies a little in different subjects, at different ages, and in different parts of the skeleton.

The colour of this tissue varies notably; and hence three varieties of marrow may be distinguished.

The first variety bears the name of *vascular* or *red marrow*, because it is of a strongly marked red colour; it is also called *fœtal* marrow, because it is the only marrow which is met with in the bones of the fœtus.

A second variety of marrow is the *gelatiniform*. In this variety the marrow, in the long bones as well as the short, presents a peculiar semi-transparency, with a grey or yellow colour, and gelatinous consistence. In some animals, it preserves during life the gelatiniform disposition, which is only temporary in man. It is found accidentally, in certain pathological or senile conditions, in some bones, following morbid alterations of the periosteum.

The third variety of marrow is that which is almost exclusively described under the names of *marrow* (properly so-called) or *fatty marrow*. It is opaque, yellow, and has sometimes been compared to adipose tissue. But it differs notably in texture, in consistence, and in delicacy.

Marrow is one of the tissues, and is composed of elements which have the configuration of cells, with a certain quantity of amorphous matter interposed, varying in proportion according to the varieties of marrow. Capillary vessels are present, arranged in meshes having nearly three or four times

the diameter of the capillary vessels themselves. The meshes are nearly of equal dimension in all directions; and are polygonal, with rounded angles. They are most readily seen in injected specimens, by washing away the marrow by a current of water, when they are found lying against the bony tissue. This has caused it to be said that the meshes are much more numerous in contact with the bone than elsewhere. The most delicate capillaries found in the marrow are larger than the ultimate capillaries of the periosteum and of the bony tissue. In the spongy tissue especially, and even where they lie against the bone, they are not distinctly cylindrical like those of the periosteum, and resemble sinuses moulded on the neighbouring parts.

In the medullary tissue are certain accessory elements called myeloplaxes. They are always found on the surface of the marrow; that is to say, in some degree, between the marrow and the bony tissue. They are more abundant in the spongy tissue than in the medullary canal of the long bones; they are also more abundant in the fœtal marrow, and in young subjects than in adults. In the adult, they are mostly found in the spongy tissue, and especially in the neighbourhood of the cartilages which adhere to the bone. Their relatively greater abundance in the bones of young subjects, depends either on the fact that their quantity diminishes in adults, or rather that the myeloplaxes have not multiplied proportionally to the other elements. Myeloplaxes are met with in the marrow which accompany the vessels in the vascular canals as far as under the periosteum; so that, when the periosteum is torn away, and the vessels entering the vascular canals are removed, myeloplaxes are also drawn away.

Another accessory element consists of fibres of laminar tissue found in certain portions of the marrow. There is, however, no internal periosteum; no layer of fibrous tissue on the interior of the bones, enveloping the marrow, and designed to separate the bony substance from the marrow. The marrow is in immediate contact with the bony substance. For a long time it was believed that this membrane existed only in the canals of the long bones, and was wanting in the spongy tissue. But, in the gelatiniform variety of the marrow, in the amorphous substance which takes a notable part in the constitution of this variety, there is a network of fine laminar fibres crossed in all directions, and in close contact sometimes with the vessels and the trabeculae of the bone. It is only in the shafts of the long bones, and in the largest medullary spaces of the spongy tissue, that this fibrillary network is found. It is wanting in the marrow which fills the smaller cavities of the spongy tissue of the extremities of the bones, of the vertebrae, sternum, etc.

In this network, the fibres are generally isolated, crossed or not. Around the bony trabeculae which traverse certain points of the medullary canal of the long bones, these fibres lie closer to each other than elsewhere, without, however, forming layers or bundles.

Here and there, in the marrow itself, these fibres are disposed in wavy bundles, slightly pressed against each other. From these bundles radiate, in a varied and very elegant arrangement, isolated fine wavy fibres, sometimes crossed; and between them lie the medullary cells, the amorphous matter (which may exist alone), capillaries, and adipose vesicles. These peculiarities of texture are developed about the middle or the end of the second year. Before this, only a few completely developed laminar fibres are found; they are yet in the state of fibro-plastic bodies, both fusiform and stellate, free or lying together in an order which it is then difficult to deter-

* *Myeloplaxes* are defined by M. Robin as consisting of large patches or flattened lamellae, sometimes polygonal, sometimes irregularly spherical. They are finely granular, and contain in their thickness from six to ten ovoid nuclei, each of which contains one or two nucleoli and molecular granules. The lamellae have a diameter of from 1-50th to 3-100ths of an inch; and the nuclei are about 1-3000th of an inch long by 1-5000th of an inch broad.

mine. Amongst the fibres, whether isolated or arranged in loose bundles, there always remain some of the fusiform or stellate fibro-plastic bodies; and in some parts, these are the centres of fibrils which radiate from their periphery. In the fatty, or partly fatty, marrow, fibro-plastic bodies are found, which have already passed into the state of adipose vesicles, and are either filled with oil or contain only a few drops. It is by the transformation of these fibro-plastic bodies into adipose vesicles that the marrow assumes the adipose state. While this transition is taking place, or in marrow which retains the gelatiniform state, fibro-plastic bodies are often seen which have passed into the state of adipose vesicles, and at the same time serve as centres of radiation to two or more laminar fibres; or they seem as if joined to some fibres of the fibrillary network. In the transparent marrow of emaciated subjects, these facts are equally well seen; but the vesicles contain towards their centre only one or two large drops of oil of a deep yellow colour, strongly refracting the light, together with smaller ones, of the same or a paler tint, surrounding them.

II.—VARIETIES OF COLOUR AND TEXTURE PRESENTED BY MARROW.

Let us now see what are the peculiarities of texture which give, in certain cases, a red aspect to the marrow; while, in others, it presents a gelatiniform appearance; and again, in other circumstances, it assumes the adipose state, which has nearly always been taken as the type of description of marrow.

The fetal, or red marrow, owes its colour to being composed chiefly of medullary cells, with some vessels and a small quantity of amorphous matter. The medullary cells, which seem to form with the vessels about eight-tenths of the whole of the tissue, do not appear to contain any drops of fat in their interior. The marrow thus constituted is gradually, in the course of its development, replaced by a semi-transparent, grey, gelatiniform tissue. This change of colour, this passage of the first variety to the second, is owing to the fact, that the amorphous substance interposed between the medullary cells increases, in certain conditions, more than the cells themselves; so that the medullary cells in gelatiniform marrow are separated one from another by a large quantity of semi-transparent homogeneous substance, having a gelatiniform aspect.

This gelatiniform marrow is sometimes grey; sometimes it has a nearly semi-transparent yellow colour. Its grey colour depends on the absence of adipose cells between the other elements; and the yellowish appearance depends on the separation of the medullary cells and the presence of adipose vesicles.

It has already been seen that it is by the transformation into adipose vesicles of the fusiform or stellate fibro-plastic elements of the laminar fibres that the fatty marrow is formed. Here the amorphous matter disappears, and the fibres of the network, as well as the medullary cells, are compressed between the adipose vesicles. But when the marrow passes into the gelatiniform state in consequence of emaciation, or when it returns to the red state in consequence of inflammation, or of the presence of a tumour on the bone or in the medullary canal, the amorphous matter reappears, and the medullary cells again become visible in even greater number than before.

There is a great difference between marrow rich in fatty vesicles, and adipose tissue. In the marrow, the cells are simply placed in juxtaposition; the medullary cells being interposed, and the amorphous matter remaining in some parts. The adipose

cells are not disposed here in lobules, separated one from another by partitions formed by laminar fibres, as in the adipose tissue. Farther, the size and the form of the capillary meshes are different. Hence, the medullary tissue is more soft; the fatty vesicles are more easily ruptured than in adipose tissue.

The passage of marrow into the adipose state takes place more in certain bones than in others. Very frequently, the long bones are filled with yellow or adipose marrow; while the bodies of the vertebrae, the sacrum, and the sternum, still contain the red variety. The flat bones sometimes contain reddish marrow in their diploe, while the long bones are filled with yellow fatty marrow. Fatty marrow is relatively less vascular than gelatiniform marrow or yellow marrow. These differences of the marrow of one bone from another in the same subject deserve careful study.

The red, gelatiniform, and fatty varieties of marrow, are found, with analogous peculiarities of texture, in most mammalia, varying with the species as well as with the age in the same species. Amongst ruminants, especially those which are fattened, the marrow passes at an early period into the adipose state. In the hog, it remains much longer of a reddish-grey colour, poor in adipose vesicles, and, on the contrary, richer, at least relatively, in medullary cells and amorphous matter.

In the dog, as soon as the animal has attained about its full size, the marrow in the canals of the long bones is of a yellowish-red colour, and a soft and pulpy consistence. It is then about one-half or two-thirds composed of medullary cells, with free nuclei and complete cells in nearly equal proportions. These elements are contiguous, or are separated one from another by a small quantity of amorphous matter. Here and there, large adipose cells, breaking down under the least pressure, are found either separate or collected into small masses of two, three, or more, thus giving a yellowish colour to the tissue. In the extremities of these bones, and in the short and flat bones, the marrow is red, and contains no adipose vesicles, or only very few. Small myeloplaxes, possessing two or three nuclei only, are still seen.

The marrow possesses only the vegetative properties—nutrition, development, and reproduction. But the nerves which accompany its nutritive vessels are sensible to pricking and tearing, as Duverney pointed out.

The marrow is formed after the bony tissue; the latter is compact at first, even in long bones; and it is only when the central parts of the bone are absorbed, that cavities are formed which become filled with marrow. Hence, it is impossible to admit that the medullary tissue arises from embryonic cells, as some authors suppose, who would directly connect the generation of all anatomical elements with the cells proceeding from the segmentation of the yolk.

III.—MORBID MODIFICATIONS OF MARROW.

The morbid modifications which may be presented by the marrow are sometimes direct; that is to say, the marrow may, without change of volume or quantity, present certain alterations, as in inflammation. When the marrow, which has presented a yellow colour, becomes inflamed, it takes an intense red colour, owing to the multiplication of the medullary cells, and to the disappearance of the fat from the adipose vesicles. In proceeding from the inflamed towards the sound parts, more and more medullary cells are gradually met with; or, *vice versa*, in a contrary direction, the fat in the adipose vesicles diminishes in proportion as the red parts are approached.

In some conditions, the inflammation becomes so

intense that the medullary cells cease to receive materials fit for their continuous molecular renovation. The marrow then softens and becomes liquid, and flows from the extremity of the fractured or amputated bone. When this liquid is examined, there are found in it only molecular granules in suspension, sometimes nucleated medullary cells, and always drops of oil; for the liquefaction melts down the walls of the fatty vesicles, and sets free the oil. This is always a grave fact, as has been demonstrated in the study of fractures, especially those of long bones, and in certain other pathological conditions, as amputations followed by so-called purulent infection.

Very frequently the marrow passes from the fatty state, or the red state found in the short bones and in the fœtus, to the gelatiniform state, in consequence of the presence of a tumour in the neighbourhood of the bone. When an ulcer exists on the anterior aspect of the tibia, or when a tumour is adherent to the bone, the marrow at this level very frequently presents a gelatiniform aspect, although preserving the fatty state in the rest of the bone. Commonly, also, in cases of white swelling the marrow is gelatiniform in a part of the bone. In these circumstances, amorphous matter is produced in a considerable quantity in that marrow which has assumed the gelatiniform state; and it is this which gives to the tissue its peculiar semi-transparency. Sometimes, but especially in white swellings, small yellowish masses in the centre become gelatiniform, because the change does not take place equally through the whole extent of the marrow. These small fatty masses give a peculiar aspect to the diseased part. It has often been believed that these small yellowish masses are new productions; but they are simply small masses of cells in which the fat is not absorbed.

The name of myeloid tumours has been generally applied to tumours originating in the marrow. This expression may be accepted; but it is bad in this sense—that these tumours have no analogy in exterior aspect or in texture with the marrow of bones.

Some tumours are due to an excessive production of medullary cells or fundamental elements of the medullary tissue. These tumours are the most rare; and they nearly always contain many more free nuclei than completely formed medullary cells. These tumours are more frequently met in the spongy portions of the bones and in the flat bones, than in the shafts of the long bones. The cells and nuclei, multiplying without measure, form a more or less considerable mass which always presents a reddish grey colour, and is remarkably friable. This is due to the fact, that the medullary cells and nuclei are accompanied by a much smaller quantity of vessels and of interposed amorphous matter, than exist in normal marrow. When these tumours increase in size, they frequently assume an encephaloid appearance. This encephaloid aspect, however, does not indicate the character of the tumour; for several kinds of tumours may, at various periods of their evolution, present a greyish or whitish colour, and a softness comparable to that of the substance of the encephalon. This state is generally owing to the production of fatty granules, either in the constituent elements or between them. In the particular case of tumours formed by medullary cells, the encephaloid aspect results from the production of granules, mostly fatty, principally interposed between the medullary cells, a few only being formed within them. In these tumours, adipose vesicles are not produced, notwithstanding the presence of a certain amount of fibro-plastic laminar fibres, as in healthy marrow. This interposed fat is not yellowish fat, like that which exists in normal marrow; it is a fat which reflects a white light, and has a very powerful refrac-

tive power. These tumours may encroach upon the bones and neighbouring tissues, producing atrophy in them. They are very commonly produced in the thickness of long bones or of the spongy tissue, and, after producing absorption of the bone, encroach upon the neighbouring parts.

The second species of tumour which is developed at the expense of the medullary tissue, comprises the tumours resulting from the excessive production of myeloplaxes, accessory elements of the marrow. These tumours may be produced everywhere where there are myeloplaxes; for the myeloplaxes accompany the vessels as far as the periosteum. These are the most common tumours which are derived from the medullary tissue. Their tissue has no exterior analogy with that of the healthy marrow; it resembles muscular tissue in colour and consistence.

These tumours may attain very variable dimensions in different parts. Their consistence varies according to the periods of their evolution. Not unfrequently they undergo softening after having attained a large size; and this softening nearly always coincides with certain modifications of texture. The myeloplaxes forming the fundamental element of these tumours are mixed generally with laminar fibres, either completely developed or in the state of fusiform bodies; but medullary cells are scarcely ever found.

When these tumours acquire a certain size, they are seen to consist in some parts exclusively of myeloplaxes; while, in others, fatty granules are deposited here and there, so that some portions of the tumour have a yellowish or orange-yellow tint, while others preserve the ordinary red colour; producing a remarkable marbled aspect. At the same time, fatty granules are deposited between the myeloplaxes. Then, in all these parts, the tissue loses its consistence, which has been compared to that of muscular tissue, and which has obtained the name of osteosarcoma for it. It is very common in these cases to see softening of the morbid product; and the name of encephaloid tumour has been given to it, because there is some resemblance in consistence and colour to the encephalon. It is but moderately vascular—much less so than many other morbid products.

These tumours are generally developed in the spongy tissue, rather than in the shafts of the long bones. Wherever these tumours are developed, the vessels, arterial as well as venous, become enlarged; so that pulsation may often be perceived, whence the name of aneurismal tumours, or aneurism of bone, has sometimes been given to them. The vessels, however, which produce the pulsations, are situated on the surface of the tumours, or in the partitions which divide them into several lobules. They always arise in the network itself formed by the myeloplaxes, in which the capillary vessels are relatively scanty.

These tumours differ much in texture and in form from those which arise from medullary cells; and they also differ notably from many other tumours with which they have been confounded under the name of cancer, osteosarcoma, etc. Heterotopic generation of the constituent elements of the marrow has not yet been observed, notwithstanding that heterotopic generation of epithelial, glandular, and other tissues, has been noticed. In certain fibrous tumours, sometimes developed in contact with the periosteum, but sometimes at a distance from it, myeloplaxes may be met with. In the case of heterotopic production of cartilage—that is to say, in vascular enchondromata—marrow analogous to that of the bones may be found. It is the abnormal production of the cartilage which determines this generation of marrow.

THE AMENDMENT OF THE MEDICAL ACT.

DR. ROBERT HUNTER—a name which the public prints have lately made very familiar to the eyes of all of us—has addressed a letter to Sir George Grey, complaining of the oppressiveness of the Medical Act. He demands that the 46th Clause of the Act be expunged, and that the words “before the day of October 1858” be omitted “from the eleventh qualification entitling to registration in Schedule A.” This would, he says, enable every medical man properly educated, and who duly received his degree as Doctor of Medicine after examination to register his qualifications, whether these were received in the mother country, in the colonies, or abroad. It would save them from outrage and wrong.”

Dr. Hunter's letter was forwarded to the President of the Medical Council with a request that the General Council would favour Sir G. Grey with observations thereon. The following is the reply of the President to the Under Secretary of the Home Department.

General Council of Medical Education and Registration
of the United Kingdom,
32, Soho Square, London, W., May 15th, 1865.

SIR,—I have the honour to acknowledge the receipt of your letter of the 4th inst., enclosing a copy of a letter from Dr. Hunter, on which you ask, by desire of Secretary Sir George Grey, the observations of the General Medical Council.

I have laid that letter before the Executive Committee of the General Medical Council, to which the duty has been delegated by the Council of communicating with the government respecting the amendment of the Medical Act; and am desired by the Committee respectfully to submit to Sir G. Grey the following observations on the subjects to which Dr. Hunter's letter relates. The admission of foreign and colonial degrees and diplomas to registration in the United Kingdom, in the manner demanded by Dr. Hunter, would be wholly opposed to the principles of the Medical Act of 1858, which Act, it is to be observed, deprived the holders of such degrees and diplomas of no legal privileges whatsoever; for they possessed none, as medical practitioners, in this country, before the passing of that Act.

Many of them, indeed, were practising here without legal sanction; some of them in direct contravention of the rights, then existing, of the College of Physicians and of the Society of Apothecaries.

It is notorious that, prior to 1858, the number was yearly increasing of persons who came to practise in this country with diplomas obtained from certain universities in Germany, and, more largely still, from societies or colleges, as they were called, in America, such diplomas having been obtained with a facility fatal to their respectability, and hence subversive of the credit of the profession to which the holders of them claimed to belong, as likewise of the safety of the public.

Under such circumstances it was not intended, by the Act of 1858, to legalise foreign and colonial degrees and diplomas any further than was requisite to prevent the Act from having a harsh and retrospective effect on those holders of them who had already succeeded in establishing themselves in practice in this country.

But no such diplomas were to be registered which should be obtained subsequently to the passing of the Act in 1858.

The main objects of the Medical Act were, first, the formation of a register to enable the public to ascertain who are qualified to practise medicine or sur-

gery; and, secondly, the establishment of a Council of Medical Education for the purpose, among others, of preventing thenceforth the intrusion on the register of incompetent, or, at least, uneducated persons.

The latter object was to be obtained by empowering the Council to supervise the education of medical students, and the examinations instituted by the bodies authorised to grant medical and surgical qualifications; and, if necessary, to enforce, with the aid of the Privy Council, the amendment of defects in education or examination.

It is evident that, as regards foreign, and even colonial qualifications, the same powers could not be granted to the Medical Council, nor could they be exercised by the Council with the same facility.

It remains that, in order to carry into effect the purposes of the Medical Act, the holder of a foreign or colonial qualification, must, if he desires to be registered in the United Kingdom, obtain a British qualification also; which, if he be a competent person, he may readily do, from one or other of the nineteen bodies enumerated in Schedule A to the Medical Act. For these bodies have, with the encouragement of the Medical Council, made liberal arrangements for the reception of foreign and colonial licentiates and graduates, whose competence to practise has been or can be sufficiently ascertained.

It is, on the one hand, the interest of these bodies to receive and license such persons; whilst, on the other hand, it is the duty of the Council, in the interest of the public, to guard against their reception with too great facility.

The Medical Council has accepted the regulations of the licensing bodies to this effect, and has on no occasion objected to them. The Royal College of Surgeons of England has, indeed, in its list of recognised institutions, the following foreign and colonial institutions:—

Foreign.—Paris, Montpellier, Strasburg, Berlin, Vienna, Heidelberg, Bonn, Göttingen, Würzburg, Leyden, Liège, Pisa, Pavia, Royal Caroline Institute, Stockholm; Copenhagen, New York, Philadelphia, Harvard University, Boston.

Colonial.—The Medical College of Bengal; the Medical College of Madras; the Grant Medical College at Bombay; Canada—the University of Toronto; the University of McGill College, Montreal; the University of Queen's College, Kingston; Australia—Melbourne Hospital.

The regulations of the College of Physicians of London afford at least equal facility in this respect with those of the College of Surgeons of England.

The Medical Act would fail in its purpose if it did not require that possessors of foreign and colonial diplomas, who desire to be placed on the British Register, should furnish some guarantee of fitness to practise equal to that required from students in British schools.

With respect to the letter said to have been addressed by a registered practitioner to the General Medical Council, during its late sitting, and never to have been acknowledged, if such an omission occurred it could only have been accidental, and must be a subject of regret to the Council. But though it is impossible to affirm that no such letter may have been addressed to an individual member of the Council, it has been ascertained by strict inquiry that no letter, sent regularly for submission to the Council, and duly delivered, has been suffered to remain without acknowledgment.

I have the honour to be, Sir,
Your obedient servant,
GEORGE BURROWS, M.D., President.

II. Waddington, Esq., Under Secretary of State
for the Home Department.

THE CHEMISTS AND DRUGGISTS BILLS.

THE following petition has been presented from the Manchester Medico-Ethical Association.

To the Honourable the Commons of Great Britain and Ireland, in Parliament assembled.

The petition of the undersigned, on behalf of the Manchester Medico-Ethical Association, humbly sheweth—

That the interests of the public require careful, qualified, and authorised dispensers of drugs and chemicals, throughout the United Kingdom.

That the sale of poisons, notwithstanding recent legislation, is in a very unsatisfactory position.

That the rapidly increasing tendency of the registered medical practitioner to write prescriptions instead of furnishing medicines, calls for an intelligent class of druggists, who shall have given guarantees of fitness for their duties by having passed an authorised and definite examination.

That, for the above and other reasons which will occur to your honourable House, an Act for the regulation of the education and practice of druggists is imperatively called for.

That a Bill lately introduced by Sir Fitzroy Kelly, with such amendments as your honourable House will see necessary, appears to the undersigned to be well fitted to carry out the views of your petitioners.

Your petitioners, therefore, humbly pray—

That your honourable House will, in this present session of Parliament, pass such a measure as will beneficially regulate the sale of poisons, and ensure the dispensing of pure and unadulterated drugs; but which, at the same time, will not confer, actually or by implication, any right or claim on the chartered or authorised druggists to practise medicine or surgery in contravention of the Medical Act of 21 and 22 Victoria, cap. xc.; or in extension of the privileges mentioned in the charter of the Pharmaceutical Society.

And your petitioners will ever pray.

Signed on behalf of the members of the Manchester Medico-Ethical Association.

J. L. BARDSLEY, M.D., Kt., *President.*

JONATHAN WILSON, M.R.C.S. } *Hon.*

J. THORBURN, M.D. } *Secs.*

Manchester, May 9th, 1865.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION:
ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFRESON, M.B. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S. Ed., Professor of Clinical Surgery in the University of Edinburgh.

Gentlemen intending to read papers, cases, or any other communications, are requested to give notice of the same to the General Secretary, at their earliest convenience.

T. WATKIN WILLIAMS, *General Secretary.*

13, Newhall Street, Birmingham, May 16th, 1865.

COMMITTEE OF COUNCIL:
NOTICE OF MEETING.

THE Committee of Council will meet at the Queen's Hotel, Birmingham, on THURSDAY, June 22nd, at Three o'clock *precisely*.

Business. To receive communications from the President.

To consider the Programme for the Annual Meeting.

To prepare the Report to be presented at the Annual Meeting.

To consider a Communication from Mr. Gamgee; and a correspondence between that gentleman and the Editor of the JOURNAL.

Any other business which may be brought forward.

T. WATKIN WILLIAMS, *General Secretary.*

13, Newhall Street, Birmingham, June 6th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
BIRMINGHAM AND MIDLAND COUNTIES. [Annual.]	Hen and Chickens Hotel, New Street, Birmingham.	Friday, June 16th, 3.30 P.M.
LANCASH. & CHESHIRE. [Annual.]	Royal Institution, Manchester.	Wednesday, June 21.
SOUTH-EASTERN. [Annual.]	Crystal Palace, Sydenham.	Thursday, June 22, 1 P.M.
MIDLAND. [Annual.]	Town Library, Town Hall, Leicester.	Wednesday, June 22th, 2 P.M.
NORTHERN. [Annual.]	Library, Newcastle-upon-Tyne Infirmary.	Wed., June 23, 10.30 A.M.
METROPOL. COUNTIES. [Annual.]	Crystal Palace, Sydenham.	Tuesday, July 4th, 3 P.M.
NORTH WALES. [Annual.]	Royal Hotel, Rhyl.	Tuesday, July 4, 12 noon.
WEST SOMERSET. [Annual.]	Clarke's Castle Hotel, Taunton.	Tuesday, July 4, 2.30 P.M.

LANCASHIRE AND CHESHIRE BRANCH.

THE Annual Meeting of the Lancashire and Cheshire Branch will be held on Wednesday, June 21st, in the Royal Institution, Mosley Street, Manchester; THOS. TURNER, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Honorary Secretary, without delay.

WM. ROBERTS, M.D., *Hon. Secretary.*

89, Mosley Street, Manchester.

BEQUESTS. Mr. William Hollins, of Over-Wallop, Hants, has bequeathed the bulk of his property to charitable institutions, of which the following are the most prominent. £2000 to Winchester Hospital, £2000 to Salisbury Infirmary; these two institutions will also take any surplus residue. £1000 to each of the thirteen following institutions—Brompton Hospital, Bethlehem, St. Luke's, Westminster Ophthalmic Hospital, Refuge for the Destitute at Dalston, London National Benevolent Institution, Deaf and Dumb Children's Asylum, Infant Orphan, Church Missionary, Bible Society, Strangers' Friend Society, Accident Relief Society, and Indigent Blind Visiting Society. £700 to the Royal Free Hospital. £500 to each of the following—The London Hospital, Middlesex Hospital, Seamen's Hospital (*Dreadnought*), Irish Society of London, King's College Hospital, Queen Adelaide's Fund, Colonial Church and School Society, St. Mark's Hospital, Royal Infirmary for Children, St. Mary's Hospital, London Fever Hospital, Small-pox Hospital, St. George's Hospital, London Ophthalmic Hospital, Indigent Blind School, Great Northern Hospital, Westminster Hospital, University College Hospital.

SOUTH-EASTERN BRANCH.

THE Annual Meeting of the South-Eastern Branch will be held at the Crystal Palace, on Thursday, June 22nd, at 1 P.M.; EDWARD WESTALL, M.D., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Secretary, on or before Saturday, June 17th.

C. HOLMAN, M.D., *Secretary*.

Reigate, June 7th, 1865.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

The Council of Management hope that gentlemen will prepare papers and cases, and forward the titles of the same to Dr. Philipson not later than June 17th. Dinner at 6 P.M.

G. H. PHILIPSON, M.B., *Hon. Secretary*.

MIDLAND BRANCH.

THE Annual Meeting of the Midland Branch will be held on Wednesday, June 28th, at 2 P.M., in the Town Library, Town Hall, Leicester; JOHN BARCLAY, M.D., President.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, without delay, to the Honorary Secretary.

JOHN SLOANE, *Hon. Secretary*.

Welford Place, Leicester, June 1865.

WEST SOMERSET BRANCH.

THE Annual Meeting of the West Somerset Branch will be held at Clarke's Castle Hotel, Taunton, on Tuesday, July 4th, at 2.30 P.M.; HUGH NORRIS, Esq., President.

Gentlemen are requested to give notice to the Secretary of cases or papers they may wish to communicate.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, June 1865.

RATHER COOL. The druggists and pharmacutists say, We do not object to an Act of Parliament which shall prohibit us from prescribing; but we have a right to ask, in return, that medical men shall not be allowed to dispense their own medicines.

LUNACY COMMISSIONERS. In the Committee of Supply last week in the House of Commons, a vote of £7635 was proposed for the Lunacy Commission. Sir J. Trollope complained that there were six commissioners in England, but only two in Scotland; and that great delays took place in the transaction of business, and the most absurd regulations had been issued from time to time. He spoke now with respect to the pauper lunatic asylums. Sir G. Grey said there had been frequent discussions between the commissioners and magistrates of counties on the subject of want of ground in connection with the asylums. He thought the former were right in requiring that there should be ground sufficient to allow of the patients being exercised. Sir J. Trollope observed that in the case to which he had referred, there had already been thirty or forty acres of ground attached to the asylum. Sir G. Grey said he meant by exercise, employment at agricultural pursuits. Colonel Sykes expressed his opinion that the public as well as the patients were much indebted to the commissioners.

JAMES ALDERSON, M.D., F.R.S., President, in the Chair.

NOTES OF TWO CASES OF INTERMITTENT HÆMATURIA: WITH REMARKS UPON THEIR PATHOLOGY AND TREATMENT. BY GEORGE HARLEY, M.D.

THE chief peculiarity presented in the cases described in this communication was that the urine passed at one period of the day varied from a chocolate colour to an almost purple blackness, whereas at all other times the secretion was to all intents and purposes normal. One of the patients was a medical gentleman who had for many years been resident in a warm climate, where he had contracted malarial fever; the other was a Londoner who had never suffered from any true aguish attack, but in whose case the bloody urine was passed whenever he was exposed to cold. Indeed, according to the patient's own statement, during the last two winters his urine invariably became bloody about an hour after his suffering from cold hands or feet. Both patients appeared to suffer from hepatic derangement, the one whose attack could be traced to malaria being slightly jaundiced at the time the urinary symptom manifested itself. The other, although not suffering from true jaundice, had an exceedingly sallow, bilious appearance.

As regards the pathology of these specimens of urine, the author remarked that, had the morning's urine only been brought under the notice of the physician, he could never have dreamt of the existence of any urinary affection; whereas had the midday specimen alone been subjected to his inspection, he could not have failed to suspect the existence of grave organic changes in the renal organs. Neither of these opinions could possibly be correct; the varying condition of the renal secretion clearly pointing to intense congestion of the chylipoietic viscera of a transient and periodic character.

Dr. HARLEY further pointed out the difference between the affection here described and the other form of disease with which it is apt to be confounded—namely, ordinary hæmaturia. The easiest way of establishing a correct differential diagnosis was, he said, that in ordinary hæmaturia the urine is not only coagulable by heat and nitric acid, but contains blood-corpuscles, which gradually become deposited on standing, and leave a clear, pale-coloured supernatant liquid. In this form of intermittent hæmaturia, as also in some cases of the non-intermittent variety, the urine, although coagulable by heat and nitric acid, contains few or no blood-corpuscles, and the colouring matter is not deposited on standing, but remains uniformly distributed throughout the liquid. Besides this, the urine contains numerous granular tube-casts, and has an increased percentage of urea.

While the usual remedies employed in the treatment of hæmaturia failed to make the slightest impression on this form of disease, the employment of mercurials and quinine caused it rapidly to disappear.

NOTES OF FOUR CASES OF INTERMITTENT HÆMATURIA. BY WM. H. DICKINSON, M.D. CANTAB.

The case most fully reported was that of a man who had frequently been in St. George's Hospital. In the autumn of 1859 he was first attacked with his present complaint. One morning he was seized with

shivering, nausea, and pain in the loins; and when he passed urine, he found it was black and apparently bloody. From that time to the present he had often been under observation at St. George's Hospital, and he had been in the hands of all the physicians of that establishment, latterly under the care of Dr. Fuller. He had no constant ailment, but his health was broken by short attacks of hæmaturia. From the beginning of the disorder these had always been of the same character. They owned no other cause but exposure to cold. He usually got up and went to his work apparently well. In cold weather he was liable to be attacked with shivering, retching, and dull pain in the loins; at the same time yawning and feeling disposed to stretch himself. The testicles were retracted, and he had pain passing down the thighs. When he passed urine, it was black and turbid, and was found to be highly albuminous, of great specific gravity, and containing an excess of urea; the microscope showed numbers of dark granular casts, and a dark molecular deposit; no blood-globules had ever been found. The urine retained these characters for two or three urinations. When he got warm it recovered its natural characters; and next day he was well, excepting that he was somewhat reduced by the attack. In continuous cold weather these attacks had come on for several successive days, but they had never lasted through the night. He had never had an attack in the summer; though once, in comparatively warm weather, it was brought on by his washing windows with cold water. Movement had no tendency to produce it; he was always better when taking exercise, as it kept him warm. The man had an anæmic and cachectic appearance. No organic disease could be discovered. While in the hospital many plans of treatment had been tried, but none had appeared to prevent the recurrence of the complaint. Quinine proved inefficacious; mercurials were apparently injurious. While taking blue-pill, he had, for the first time in his life, an attack while in-doors. During the time he was under this treatment he had an attack of pneumonia, which was followed by peculiar symptoms of prostration, which it was thought must have proved fatal, but from which he eventually recovered.

Three similar cases were briefly reported, two of which had occurred in the practice of Dr. George Johnson, and one in that of Dr. F. Cock, which gentleman had communicated the facts to the author.

In conclusion, Dr. DICKINSON maintained that the disorder was essentially due to an alteration in the blood, a similar state of urine having been found during typhus, and also in man and animals after the inhalation of arseniuretted hydrogen. The points which the disorder has in common with ague were adverted to, but the absence of any periodical tendency and the inefficacy of quinine as a remedy were cited as essential differences. As to treatment, it was considered that as yet the disorder was beyond our reach; the most we could do was to palliate the effects of the loss of blood. Quinine was believed to be useless except in this respect; while the administration of mercurials, both on general principles and on the experience afforded by the above case, was believed to be detrimental.

THE HUNTERIAN MUSEUM. Mr. W. L. Crowther of Hobart Town has just sent over to this museum, the complete skeleton of a fine sperm whale, about sixty feet in length, which was taken last year off the south coast of Tasmania, and prepared at some considerable trouble and expense by the above gentleman, who had previously made several valuable contributions to the museum.

Correspondence.

POOR-LAW MEDICAL RELIEF.

LETTER FROM RICHARD GRIFFIN, ESQ.

SIR,—If you can find space for the following letter, I shall feel obliged, as it may be of interest to the Poor-law medical officers. I am pleased to hear that the Workhouse Visiting Society have been so far successful in their deputation to the Poor-law Board as to have induced the President to appoint a medical inspector. I sincerely trust Dr. Edward Smith's appointment may be of a permanent character, and that the Medical Department of the Poor-law Board may yet be presided over by a medical man; for, until that be the case, it will be in vain to expect a perfect system of Poor-law medical relief.

I am etc., RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, June 3rd, 1865.

Mr. Griffin to the Poor-law Board.

12, Royal Terrace, Weymouth, June 3rd, 1865.

MY LORDS AND GENTLEMEN,—On Tuesday last, in consequence, I believe, of the printed letter sent by me to each of the guardians of this Union, the subject of your circular letter respecting cod-liver oil, quinine, and other expensive medicines, was again brought under the consideration of the Board. Mr. Gulson, your inspector, was present, and informed the Board that the resolution of the Select Committee of the House of Commons on this question was only carried by a majority of one, and that the President of your honourable Board voted against it; but, as there was a majority in favour of it, your honourable Board was bound to issue the circular letter, etc. After this statement, no surprise need be evinced that the guardians decided on leaving things as they are.

My lords and gentlemen, I deeply regret that Mr. Gulson should have made this statement, as it will convey the impression to the public that your circular letter was never intended to be carried out, and thus bring into disrepute your honourable Board.

Mr. Gulson made inquiry as to whether I was permanently appointed; and, on being answered in the affirmative, said that, if I had not been, the guardians could have given me notice to determine my appointment. He also said I had given your honourable Board a great deal of trouble. I need not tell your honourable Board that a statement of this kind must convey the impression that the guardians have only to look out for a charge against me, and your honourable Board will not be slow in acting upon it. This may be a mistaken idea on my part; but I can assure you that a medical friend said to me, "Under the circumstances, I should say you had better resign." My lords and gentlemen, I fully admit I have given your honourable Board a vast amount of trouble; but I beg you will recollect, as my excuse, that I am advocating the cause of the million and a quarter of sick poor annually under treatment, and also that of the 3,100 medical officers to whom you pay a stipend so small that it averages not more than three shillings per patient. Pray bear in mind that the Select Committee on Poor Relief have by their resolution recommended "that cod-liver oil, quinine, and other expensive medicines, shall be supplied by the guardians;" thereby confirming the impression that the poor have not those medicines at present in such quantities as may be requisite. Mr. Alderman Sydney, on May 22nd, stated in the House of Commons that, "although the State paid one-half the salaries of the medical officers, those salaries

were so small that, the medical officers being required to provide their own drugs, where stimulating prescriptions were required, the people only got counterfeit prescriptions." (*Times*, May 23.) Surely, my lords and gentlemen, after this statement, made as it was by a member of the late Select Committee on Poor Relief, and in the House of Commons too, you will not allow your circular letter to become a dead letter. For the sake of the poor, I earnestly entreat you to insist upon your recommendation being at once complied with; and, in part at least, carry out the wish expressed by Alderman Sydney, "that another Parliament would not bring its labours to a close without reducing our Poor-law legislation to an useful and well-digested code."

In your circular letter, you "request the guardians, however, to be good enough to consider whether an alteration in those arrangements, as regards the supply of the medicines referred to, cannot be effected whenever a new appointment of a medical officer is made, or, with the consent of the present medical officers, during the continuance of their existing contracts." What are our contracts? Section XLVI of the Act 4 and 5 William IV directs guardians to appoint paid officers; and it empowers Commissioners to determine the continuance in office; which you have done by an order. It also declares "that when the said Commissioners may see occasion to regulate the amount of salaries payable to such officers respectively, and the time and mode of payment thereof." From this quotation it appears to me that, although a majority of your officers are permanently appointed by order, still you have the power at any time "to regulate" the amount of our salaries. That need not, therefore, prevent your directing the guardians to carry out the instructions conveyed in your circular letter. But, my lords and gentlemen, allow me to observe that you cannot, in fairness, call upon your present medical officers, out of their scanty salaries, to contribute towards the supply of that which the Select Committee believe is not now found to any great extent. If it be desirable that the poor should be furnished on a more liberal scale than at present with cod-liver oil, etc. (and I unhesitatingly say they ought to be), then call upon the guardians to consider the supply of these articles as extras, and independent of the salaries of the present medical officers, and thus at once remove the stain cast upon the medical relief of the poor both by the resolution of the Select Committee and the speech of Mr. Alderman Sydney.

I have the honour to be, my Lords and Gentlemen,
Your obedient servant,
The Poor-law Board. RICHARD GRIFFIN.

MINERAL ACIDS IN FEVER.

LETTER FROM A. B. STEELE, ESQ.

SIR,—The testimony which Mr. Howard offers in favour of the acid treatment in fever appears, unfortunately, to prove too much. Any system which can so powerfully control the ordinary course of typhus as to give the exceptional, and, I believe, unprecedented result of one hundred and twenty cases without one death, certainly will be beyond all comparison with any other method hitherto published on good authority. I believe it exceeds anything that Dr. Murchison himself would claim for the remedy he so strongly recommends, and of which he has had so much experience.

As to the corroborative opinion of Dr. Chambers, I find, on referring to his lectures published in the *Lancet* in 1858 (the only reference to his name in the copious bibliography of Dr. Murchison), that the

cases upon which he founds his views are just twenty-one in number; and of these, only twelve were subjected to the acid treatment. I must confess that a careful perusal of the statement of that popular and accomplished physician have not convinced me that he has established the superiority of the plan, which he borrowed from Dr. Mackenzie, and of which his own opportunity of observation appears to have been so limited. Besides, at the time Dr. Chambers wrote, he had not recognised the distinction (now so thoroughly established) between the different forms of fever; and this want of discrimination renders his conclusions inapplicable to a discussion of the remedy suggested for a particular form of fever only—viz., typhus.

Bearing in mind that the records of typhus, collected from all sources during many years, give five or six per cent. as a minimum death-rate; when we hear that, of "one hundred and twenty cases of low fever recently treated by Dr. Chambers's plan, not a single patient who took the acid died;" and that "during several years he has never lost a case of fever in which the acid had been exhibited for thirty-six hours,"—we are, I think, driven to these alternatives; viz., either that the "low fever" of Chambers and Howard cannot be identical with the typhus of Graves, Stokes, Corrigan, Christison, Tweedie, Murchison, or Watson, nor a disease so fatal as that which, in this town alone, caused nearly two thousand deaths in a single year (1864); or that the cases selected for the acid treatment must have been those which probably would have recovered under any circumstances.

I may, perhaps, be excused for referring to a return of the results of my own practice in fever, published in this JOURNAL (Jan. 28th, 1865, p. 103), and which has been accepted as authentic by the medical officer of health of this borough, and by the Inspector of the Privy Council; from which it will be seen that, so far as the death-rate is concerned, my treatment compares favourably with the authentic records published by authorities on fever. I am, therefore, indisposed to abandon views founded on somewhat extensive experience, in favour of what I must be pardoned for designating somewhat vague and hasty generalisations upon insufficient data.

I am, etc., A. B. STEELE.

Liverpool, June 1865.

DISEASE IN INDIA. A painful sensation has been caused by cholera breaking out with fearfully fatal results in Battery B of the Royal Artillery during its march from Mhow to Nargaum. In five days, it lost thirty-four Europeans (men, women, and children) and twenty-five natives. There has been a great mortality from a description of fever in Gwalior. The Maharajah has ordered the perpetual performance of various religious ceremonies with the view of checking the epidemic.

THE NOMENCLATURE OF DISEASE. The Council of the Epidemiological Society has, by means of circulars, endeavoured to obtain from nosologists their opinions touching the classification of diseases adopted by the Registrar-General. The answers received are for the most part commendatory of the aforesaid classification. A Committee of the College of Physicians has long been engaged in an inquiry into the nomenclature, etc., of disease; and we may expect from their report something like a satisfactory reply to the questions proposed by the Epidemiological Society. Our readers may remember that many faults in the present classification of diseases were pointed out by Dr. Christison in his Social Science address.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following members of the College, having undergone the necessary examinations for the Fellowship at meetings of the Court, on May 30th and 31st, and on June 1st, were reported to have done so to the satisfaction of the Court of Examiners, and at a meeting of the Council on June 8th, were admitted Fellows of the College.

Barnes, John Wickham, Rutland Park, Sydenham; diploma of membership dated February 18, 1853
 Barter, Clement S., Paragon, Bath; April 18th, 1859
 Barton, Alfred B., The Green, Hampton Court; Dec. 17, 1847
 Holland, Edmund, Emsworth; April 19, 1860
 Hooper, John Harward, Tenby, South Wales; April 17, 1861
 Langton, John, Bloomsbury Square; April 10, 1861
 Monckton, David H., Rugeley; December 18, 1849
 Powell, William, Tower Hamlets Dispensary; April 11, 1861
 Smith, Thomas Starkey, Warrington; April 17, 1861
 Stone, William Domett, 42, Lincoln's Inn Fields; April 10, 1861
 Teale, John William, Leeds; May 9, 1862
 Vallance, Thomas J., Stratford, Essex; June 3, 1851
 Wilkinson, John S., Davies Street; May 8, 1857

APOTHECARIES' HALL. On June 1st, 1865, the following Licentiate was admitted:—

Leigh, Thomas Drake, Shaw Street, Liverpool

At the same Court, the following passed the first examination:—

Birch, George, Guy's Hospital

APPOINTMENTS.

WINTER, John, M.D., appointed, by the Queen, Member of the Legislative Council of the Island of Newfoundland.

ARMY.

PENNINGTON, Gustaf-Assistent-Surgeon F., to be Assistant-Surgeon, vice H. W. Devlin.

VOLUNTEERS, (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

FEITH, T. F., Esq., to be Assistant-Surgeon 23rd Surrey R.V.

DEATHS.

BROWN. On May 24th, at 16, Finsbury Circus, aged 14 months, Dora Isabella, youngest daughter of Thomas Brown, Esq., Surgeon.

BURY. On May 30th, at Whetstone, Cornelia T., wife of *George Bury, Esq.

CLARK. On June 1st, Henry Drummond, third surviving son of *F. Le Gros Clark, Esq., St. Thomas's Street, Southwark.

DOWN. On June 4, at Earlswood, Redhill, aged 2, Lilian L., only daughter of J. Langdon H. Down, M.D.

GRIFFITH. On June 2, at Camberwell, John, infant son of John T. Griffith, M.D.

LUCAS, Rudd, Esq., late of Long Ashton, Somerset, at Clifton, on May 28th.

MAGEATH, Ffolliott Charles, Esq., Assistant-Surgeon R.N., on board H.M.S. *Sovereign*, on April 9.

OGLE. On June 1, at Brighton, aged 4, William J. F., son of *William Ogle, M.D., of Derby.

PALFREY. On May 28th, at 12, Wellington Street, London Bridge, aged 2, Ellen Mary Lever, daughter of James Palfrey, M.D.

PETTIGREW. On May 26th, at Onslow Crescent, Kensington, aged 47, the Rev. Augustus F. Pettigrew, M.A., third son of T. J. Pettigrew, Esq., F.R.S., F.S.A.

SKINNER, William, M.B., of Oxford Road, Manchester, aged 37, on May 27th.

SNOOK. On May 19th, in London, aged 20, Edith Mary, second daughter of *John S. Snook, Esq., of Colyton, Devon.

SYKES. On May 23rd, at Dalston, aged 9 months, Herbert G. C., son of George Sykes, M.D., Surgeon to the Queen's Own Regiment.

***VACHELL, Charles R., M.D.,** at Cardiff, on May 26.

LUNATIC ASYLUMS. Mr. Scourfield has brought in a bill to explain and amend the Lunatic Asylum Act, 1853, and the Lunacy Act Amendment Act, 1862.

MR. SMEE, the Conservative candidate for Rochester, lately addressed the electors of that city. Resolutions favourable to him were put and carried unanimously.

ST. BARTHOLOMEW'S HOSPITAL. The following gentlemen have been appointed tutors in this hospital—Dr. Duckworth, Mr. W. Morant Baker, and Mr. W. L. Shepard.

MEDICAL CANDIDATES FOR PARLIAMENT. The members of the medical profession who are now in the field as candidates for seats in Parliament, are Sir Charles Locock for the Isle of Wight, Mr. Mitchell Henry for Woodstock, and Mr. Smee for Rochester.

THE BRITISH ASSOCIATION. At a meeting held at Nottingham, it was resolved to invite the British Association for the Advancement of Science to hold their annual meeting for the year 1866 in that town. Nearly £2000 have already been subscribed towards meeting the expenses.

THE MORGUE IN PARIS. The old Morgue, which used to stand on the Quai du Marché-Neuf, has now been completely demolished. It was built in 1804, and during its sixty years of existence received 23,000 bodies; that is, on an average, more than 340 annually.

PUBLIC GRANTS. In Committee of Supply of the House of Commons, the following grants have been made. £3007 for Inspection of Lunatic Asylums (Ireland); £6773 for the University of London; £14,455 for Universities, etc., of Scotland; £2372 for the Queen's University (Ireland); £3150 for Queen's Colleges (Ireland).

UNIVERSITY OF LONDON. In the House of Commons, on June 2nd, Mr. Grant Duff called attention to the claims of the University of London to be provided, at the national expense, with a building suitable for its purposes, and worthy of the position which it occupied among the educational institutions of the country. Mr. Cowper admitted the usefulness of the University, observing that there was every desire on the part of the Government to give to it an adequate accommodation; but he doubted the expediency of incurring the expenditure requisite to provide a special building.

A CAUTION TO ETHNOLOGISTS. An incident at a meeting of the Academy of Sciences recalls to mind the archaeological discovery of the immortal Pickwick. There was mention made some time ago of a great find of flint implements at Pressigny-le-Grand, in the vast antiquity of which MM. Quatrefages and Mortillet expressed their firm belief. M. Decaisne, however, went to the spot, and questioned people living near, who told him that in past times tramps came every year and made gun-flints on the spot, and departed, leaving, of course, their chippings behind, veritable relics of an almost forgotten age—the age of flint locks. (*Chem. News.*)

ST. MARY'S HOSPITAL MEDICAL SCHOOL. The prizes and certificates of honour were distributed on Monday, May 29th, by Professor Owen, F.R.S., as follows. *Winter Session, 1864-65: Scholarship in Anatomy, value £25, Mr. Theodore Thomas Taylor. Prize for Students of the First Year, value £20, Mr. William H. Wood; Certificates of Honour, Mr. J. Wyatt Pratt and Mr. C. H. Joubert de la Ferlé. Prize for Students of the Second Year, Mr. Henry Franklin Parsons; Certificate of Honour, Mr. James Robert Hill. Summer Session, 1864. Prize for Students of the First Year, Mr. H. F. Parsons; Certificates of Honour, Mr. John Ockenden and Mr. John George Randall. Prize for Students of the Second Year, Mr. N. Birdle Major; Certificate of Honour, Mr. T. T. Taylor. Comparative Anatomy, 1864. Prize, Mr. H. F. Parsons. Natural Philosophy, 1864. Prize, Mr. H. F. Parsons; Certificate of Honour, Mr. J. G. Randall. Practical Anatomy, 1864-65. Prize, Mr. Richard Samuel Parnell Griffiths.*

SUPPLY OF MEDICINES FOR PAUPERS. A return made by the Poor-law Board shows that in the following metropolitan workhouses, the drugs required for the sick are not supplied by the guardians, but have to be provided by the medical officer. Greenwich, Lewisham, St. Giles, Camberwell; Bermondsey, Rotherhithe, St. George, Southwark; St. Saviour, Richmond (except cod-liver oil); St. Luke, Chelsea; St. Mary Abbott's, Kensington; St. Margaret and St. John, Westminster (in part); St. James, Westminster; St. Martin-in-the Fields, St. George, Hanover Square; St. Marylebone, St. John, Hampstead; Hackney, Holborn, St. James, Clerkenwell; East London and West London.

THE PRITCHARD CASE. The indictment served upon Dr. Pritchard bears that Dr. Pritchard is cited to appear at the bar of the High Court of Justiciary, to be holden at Edinburgh, on Monday, the 3rd of July next, to answer to two charges—the one of having murdered his mother-in-law, Mrs. Taylor, by administering to her doses of antimony or other poison or poisons; and the other of having murdered his wife by similar means. There are about eighty witnesses for the prosecution, and one hundred and fifty productions. These consist of articles of clothing worn by the deceased ladies, those organs or parts of organs of the bodies which had been subjected to chemical examination, reports (medical and otherwise), letters, the prisoner's declaration, bottles of medicine, etc.

THE LATE DR. A. B. BUCHANAN. At the last annual meeting of the Glasgow Dispensary for Diseases of the Skin, Dr. McCall Anderson said: "It is my painful duty, sir, to record the death of my amiable colleague, Dr. A. B. Buchanan. A short time since, Dr. Buchanan was appointed one of the physicians to the Dispensary of the Infirmary. He entered by rotation upon his duties in the fever wards on the 1st of March; and had only been a very few days in attendance, when he was seized with typhus fever, to which he fell a victim on the 4th of April, after an illness of three weeks; thus adding one more to the names of those who, in the conscientious discharge of duty, have fallen victims to this remorseless enemy. His contributions to medical and general literature are numerous and varied. It is sad, indeed, to reflect that his last contribution to medical literature appeared in the columns of the *Glasgow Medical Journal*, when he was lying on his sick bed, within three days of his death; and that his greatest effort, one in which, for the last two years, he was engaged, the translation from the German of Kölliker's great work on Embryology, still remains unpublished. It is to be hoped, however, that ere long these volumes will be given to the profession, under the able editorship of Professor Allen Thomson, with whom he was associated in the undertaking. His mind was of a very high order. He threw himself, heart and soul, into whatever he made the subject of his studies. He loved more the pursuit of science than the monotony of practice. He was esteemed by all with whom he came in contact, loved by those who had the privilege of his friendship, and his loss is now mourned by a large circle of friends."

DIMINISHED MORTALITY IN PARIS. Recent official reports show that the mortality is decreasing in Paris, according as large sewers are constructed and wide streets run through the narrow overcrowded quarters of the old city. From the year 1709 to 1719, the mortality was 1 in 28; and from 1752 to 1762, it was still 1 in 30. From 1836 to 1841, it was 1 in 36; in 1846, 1 in 37; in 1851, 1 in 38; in 1856, 1 in 39; and at the present time, it is 1 in 40 inhabitants. The result is that at present there are 4762 fewer deaths in Paris

than there were in the year 1841. Of 8260 houses taken down, 6000 were situated in parishes where, in consequence of the overcrowding of the inhabitants, contagious diseases committed great ravages. These 8260 houses, moreover, have been replaced by 24,947 new buildings, more spacious, and well calculated to diminish mortality. Numbers of public gardens have also been opened within a few years. On Dec. 31st, 1853, there were only 540 acres of boulevards and public gardens, planted with 69,125 trees. In 1863, there were 770 acres open to the public, planted with 158,460 trees. Moreover, in 1840, there were only 86,230 yards of sewerage; at present, there are 350,000 yards. In 1840, there were only 65,000 cubic metres of pure water distributed every twenty-four hours. At present, there are 136,834 distributed, which are to be increased to 300,000 cubic metres.

THE BLACK DEATH. The Black Death, like many other plagues of its class, can be traced far back into the remote East; and there is no doubt but that it was the same disease which ravaged China and Tartary in 1333. There had been a great famine in China, preceded by floods and earthquakes, which alone destroyed 400,000 persons, and in the following year no fewer than 5,000,000 died there of this plague. From the remote East it made its way into Europe some years later. It did not arrive in Europe until 1347, fifteen years after its outbreak in China. "From China," says Hecker, "the routes of the caravans lay to the north of the Caspian Sea, through Central Asia, to Tauris. Here ships were ready to take the produce of the East to Constantinople, the capital of commerce and the medium of communication between Asia, Europe, and Africa." Contagion made its way along these channels, and Constantinople and the seaports of Asia Minor where the foci whence the disease was carried to every country of Europe. Making its way across the European continent, it committed its greatest ravages—save, perhaps, in England—in Italy, raging terribly at Florence, where it was observed and described by the poet Boccaccio. Passing along the shores of the Mediterranean, it invaded France by way of Avignon, spreading thence to England on the one hand, and to Germany on the other; whence, like the cholera of the present day, it doubled back, two years later, to Russia, and so back to the East. The Black Death was of the same nature as the Oriental plague—viz., a putrid typhus, only of greater malignity. The boils and bubos of the latter disease were found in the former whenever the patient lived long enough to permit their development. The inhabitants of Europe at that time have been computed at 105,000,000—a high estimate. Of these 25,000,000, or one-fourth of the whole, perished! In England it was still more fatal, owing, probably, to the ruder habits of the people. During the term of one year—viz., from August 1348, to August 1349, three-fourths of the whole population perished! This terrible scourge, having swept over the then known world, committing such destruction of life, and leaving behind it such misery and poverty as the world never saw before nor since, at length died out. It spared neither age, sex, nor condition; the rich and the poor alike succumbed. There died in Venice the aristocratic, no less than 100,000 persons; in Florence the refined, 60,000; in Paris the gay, 50,000; and in London the wealthy, 100,000; while in busy, rich, industrious Norwich, there died the almost incredible number of 50,000 persons—nearly the whole, one would suppose, of its inhabitants! At Avignon the deaths occurred with such frightful rapidity as wholly to baffle the attempts of the living to inter their friends and relatives; and the Pope was obliged to consecrate the Rhone to

allow of the dead bodies finding a hallowed resting place upon its bosom, until it finally committed them to the great deep. (*Cornhill Magazine*.)

OPERATION DAYS AT THE HOSPITALS.

MONDAY......Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TUESDAY.....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.

WEDNESDAY....St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.

THURSDAY.....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.

FRIDAY......Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

SATURDAY.....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."

TUESDAY. Royal Medical and Chirurgical Society. 8 P.M., Ballot; 8.30 P.M., Dr. Wynn Williams, "On Tuberculosis"; Dr. B. Sanderson and Mr. Hulke, "Case of a Sixpence in the Larynx for Ten Weeks"; Mr. W. M. Baker, "On the Hæmorrhagic Diathesis"; Mr. Spencer Wells, "On Ovariectomy."—Zoological.—Ethnological.

WEDNESDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."—Microscopical.

THURSDAY. Zoological.—Royal.—Linnæan.—Chemical.

FRIDAY. Royal College of Surgeons of England, 4 P.M. Professor Fergusson, "On the Progress of Surgery during the Present Century."

SATURDAY. Association Medical Officers of Health.

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the Editor, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

NEMO.—As both parties have had their say in the JOURNAL, and are contented to leave the matter as it now stands, we do not think it would be advisable to reopen the matter.

THE PROPOSED QUARTERLY JOURNAL.—SIR: Your allusion to Phaeton, in the article on Mr. Carter's "four-in-hand Quarterly," caused me to look into Lemprière, and there I read that which perhaps may be an useful warning at this time.

"No sooner had Phaeton received the reins from his father, than he betrayed his ignorance and incapacity to guide the chariot. The flying horses became sensible of the confusion of their driver, and immediately departed from the usual track. Phaeton repented too late of his rashness."

Ovid (*Metamorphoses*) informs us that, having set the world on fire, he was struck from his chariot by a thunderbolt thrown by Jupiter; that he fell into the river Eridanus or Po, and was buried by the Naiades, who placed the following epitaph on his tombstone:

"Hic situs est Phaëton, currus Aurigæ paterni,
Quem si non tenuit, magnis tamen excidit ausis."

I am, etc., AN ASSOCIATE.

MR. CARTER'S LETTER TO THE MEMBERS OF THE ASSOCIATION.—SIR: In a recent number of your JOURNAL, you have given an account, which seems to me not to be in all respects an accurate one, of my recent letter to the members of the Association. I think you would act most fairly towards the Association on the one hand, and towards myself on the other, if you were to reprint my letter in the JOURNAL; as the edition published is not sufficient to supply the members. In order that you may do so, I send you herewith a copy of the "Letter," in which an error of the press is marked for correction.

Perhaps you will have the goodness to acknowledge this communication in the next number of the JOURNAL; and to state whether my request will be complied with.

I am, etc.,

ROBERT B. CARTER.

Stroud, June 2nd, 1865.

[We have already given what we believe to be a very accurate summary of Mr. Carter's project; and, in doing so, have thereby called the especial attention of the members of the Association to the fact, that Mr. R. B. Carter has published a pamphlet on the subject of the JOURNAL, addressed to them. Our advertising columns inform our members that the pamphlet may be purchased for threepence. Assuredly, therefore, it may be reasonably expected that every member who is anxious on the subject, will not grudge a few pence to make himself master of Mr. Carter's words in full. Mr. Carter has, no doubt, a high opinion of the value of his proposal; but everyone whom we have heard speak of it, regards it as wild and impracticable; and therefore we feel we should not be "acting fairly towards the Association" if we occupied valuable space in the JOURNAL by giving it admission. Ed.]

THE PROPOSED ALTERATIONS IN THE "BRITISH PHARMACOPOEIA."—SIR: As by your leading article of May 13th, it appears certain that a new edition of the *British Pharmacopoeia* is in preparation, I think it would tend to bring the present volumes (8vo. and 32mo.) of the first edition into use, if the alterations which it is intended to make were printed in sheets 8vo. and 32mo. size, so as to be capable of being bound up with the volumes which the profession has already purchased. Unless something of this kind be done to prevent our first edition copies being made useless and obsolete by the second edition, I fear the result in practice will be, the profession generally will not purchase the second edition; and, as a consequence, a tacit neglect of both editions of the *British Pharmacopoeia* will result, and the *London Pharmacopoeia* of 1851 will long continue to be our guide.

If you think with me on this subject, pray urge the Medical Council to consider its adoption before proceeding to print.

I am, etc.,

ASHLEY G. OSBORN.

Dover, May 31st, 1865.

A CORRESPONDENT writes:—"A young woman who wishes to be trained, on Miss Nightingale's plan, as a nurse, wants to know where she must apply for an account of terms, conditions, &c."

[All information necessary may be obtained on application to the Lady Superior, St. John's House, 7, Norfolk Street, Strand.]

SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

T. WATKIN WILLIAMS, General Secretary.

Birmingham, June 1865.

COMMUNICATIONS have been received from:—Dr. GEORGE JOHNSON; Mr. ALLISON; Mr. R. B. CARTER; Mr. A. B. STEELE; Dr. THORBURN; Mr. STONE; Dr. T. K. HORNIDGE; Mr. RICHARD GRIFFIN; Dr. J. SLOANE; Dr. W. KING; Mr. W. J. COLLSON; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Dr. W. M. KELLY; Mr. D. KENT JONES; Dr. JAMES RUSSELL; Mr. W. G. DAVIS; Mr. CALLENDER; Dr. HOLMAN; and Dr. JOHN THOMPSON.

Birmingham and Midland Eye

HOSPITAL, TEMPLE ROW. A SPECIAL MEETING of the GENERAL COMMITTEE will be held on Wednesday, the 21st day of June next, for the purpose of Electing a HOUSE SURGEON to the above Charity, where upwards of 7000 Patients are relieved annually. He will be required to be a member of one of the Colleges of Surgeons of Great Britain or Ireland.

Salary, £50 per annum, with Apartments, Board, and Attendance. Testimonials to be addressed to the Chairman of the Medical Committee, and sent on or before the 15th of June.

Further particulars may be had on application to the Secretary.

By order of the Committee. W. W. LLOYD, Secretary.

Weiss's Illustrated Catalogue,

containing nearly 800 engravings of Surgeons' Instruments and Apparatus, classified for their various purposes. Price, 5s.

62, Strand, London.

"This catalogue has many and great merits. It is modest, truthful, carefully arranged, and extremely well illustrated. In the great majority of cases the name of the surgeon is appended to the modification which he has introduced, and frequently other makers' names are honourably attached to instruments which they first originated. These are large principles of honour which we are glad to see strictly observed in this catalogue."—*Lancet*, September 12th, 1863.

Classical and Mathematical.—

Dr. STEGGALL prepares Gentlemen for their Examinations in Classics and Mathematics at all the Medical Boards, viz., the Preliminary Examination at Apothecaries' Hall; the Matriculation Examination of the London University; Preliminary and Fellowship Examination at the Royal College of Surgeons, etc.

Dr. STEGGALL continues his Instruction for all Medical and Surgical Examinations during the summer months.—Address Dr. STEGGALL, 2, Southampton Street, Bloomsbury Square, London.

Bass's East India Pale Ale.—

BARCLAY'S PORTER AND STOUT.

In 18-Gallon Casks, Bottles, Half-bottles and Imperial Pints.
Also DEVONSHIRE CIDER.

BERRY BROS., & CO., 3, St. James' Street, London, S.W.

Surgical Instruments.—Arnold

& SONS continue to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under their own superintendence.

ARNOLD & SONS, 35 and 36 West Smithfield, E.C.

Established 1819.

CHOCOLAT-MENIER.

(Manufactured only in France.)

Annual Consumption exceeds 4,000,000 lbs.

The healthiest, best, and most delicious Aliment for Breakfast known since 1825; defies all honest competition, unadulterated, highly nutritious, and pure. Sold in ½ lb. Packets.

Also, especially manufactured for eating as ordinary sweetmeats, or at dessert.

Wholesale, MENIER, 23, Henrietta Street, Covent Garden, London. Retail, by all respectable houses.

Aerated Lithia Water.—

Messrs. BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original Manufacturers under Dr. GARRON'S instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE or AMMONIA.—Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47, Piccadilly.

Pepsine and Pepsine Wine.—

M. BOUDAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Her Majesty's Chemist, 277, Oxford Street, London, to whom all applications respecting it must be addressed.

Third Edition of Boudault on "Pepsine", with further Remarks by Dr. Corvisart Physician in Ordinary to the Emperor of the French; edited by W. S. SQUIRE, Ph.D. Published by J. Churchill, London. May also be had of the Author, 277, Oxford St. Price 6d.

Salmon's Obstetric Binder, for

immediate use after delivery. 5s. each.

SALMON'S ELASTIC ABDOMINAL BELTS, adapted for all cases requiring support, especially for Ladies' use before and after Accouchement, from 12s. to 42s.

Elastic Stockings, from 4s. to 16s. Knee-caps, Trusses, Suspensories, Railway Conveniences, Chest Expanders, etc.

Mrs. Salmon attends upon Ladies.

HENRY R. SALMON, 32, Wigmore Street, Cavendish Square, London, W. Private Door.

Important Notice to the Profes-

SION.—PATENT (COOKED) FOOD, for INFANTS and INVALIDS.—DR. RIDGE'S PATENT.—The best wheaten flour is put into the apparatus, where every particle is brought under the uniform temperature of 212° for eight hours, which thoroughly cooks it; and as all moisture is driven off, the nutritive quality of the flour is largely increased, while it is so light and digestible that the powers of the feeblest stomach are not taxed, but can easily appropriate it. A sample for examination will be forwarded free to any medical man who may desire it.—Manufactory—Horselydown, London, S.E.

HUNGARIAN WINES.

MR. MAX GREGER (from HUNGARY),

SOLE PROPRIETOR OF

THE DEPOT FOR GENUINE HUNGARIAN WINES,

Begs to inform the public that he has appropriated a convenient room above his vaults at 7, MINING LANE, E.C., London, where every description of Hungarian Wines can be tasted free of any expense.

Ready for supply, sample dozen cases, each containing two bottles of six different kinds of such wines, which are highly recommended by the Medical Faculty. Prices at 21s., 30s., 36s., and 42s. per case. Carriage free. Cash on delivery.

Country orders to be accompanied by P. O. O. or cheques crossed the East London Bank.

THE

MEDICAL & GENERAL PROTECTION SOCIETY OF ENGLAND.

Offices—42, Great James Street, Bedford Row, W.C.

OFFICE HOURS, 10 to 4. SATURDAYS, 10 to 2.

The objects of this Society are—

1st. The Collection of Debts for Subscribers at a commission of £5 per cent. on all sums recovered without legal proceedings up to £100; above that amount 2½ per cent. Should proceedings be taken then no commission payable except on sums under £5.

2nd. To provide Subscribers with legal advice at all times. The Solicitor to the Society is in attendance at the Offices daily.

The Subscription to the Society is £1:1 per annum for Town Subscribers, and £1:5 for Country.

Prospectuses and all further particulars may be obtained at the Offices of the Society.

JAMES CHIDWICK, Secretary.

Notes

ON

THE PATHOLOGY AND TREATMENT OF CHOLERA.

BY

GEORGE JOHNSON, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN KING'S COLLEGE; PHYSICIAN
TO KING'S COLLEGE HOSPITAL; ETC.

[Continued from page 527.]

WE have shown in previous communications (pp. 449 and 527) that two classes of facts stand in bold opposition to the theory that the collapse of cholera is due to a drain of liquid from the blood. We have seen that there is no such direct relation between the degree of collapse and the amount of liquid discharged from the blood as must exist if the hypothesis in question were true. We have also seen that the symptoms of collapse differ essentially from those which an excessive drain of fluid from the blood is known to produce. We have now to inquire *whether the effect of various and opposite modes of treatment upon the symptoms of collapse affords support to the theory that a drain of liquid from the blood is the essential or the chief cause of that condition.*

The Effect of Alcoholic Stimulants. The condition of a patient in collapse—cold and pulseless, and apparently exhausted—is one which naturally suggests the use of stimulants. Any one who has witnessed the speedy improvement in the pulse and other symptoms, which usually follows the administration of wine or brandy to a patient who is fainting from loss of blood or exhausted by excessive purging, might reasonably expect to obtain similar results from the same means in the collapse of cholera. Accordingly, stimulants have been given, and given freely and boldly; and the result has been a very general conviction that in the stage of collapse they are not only useless, but positively injurious. Again and again have I seen a patient grow colder, and his pulse diminish in volume and power, after a dose of brandy, and apparently as a direct result of the brandy. Dr. Gull (*Report on the Morbid Anatomy and Pathology of Cholera*, p. 185) states that, “although opium and diffusible stimuli—brandy, camphor, and ammonia—were useful at an early stage of the disease, as collapse set in, they not only failed to produce any favourable result, but often aggravated the symptoms.”

Dr. Paine, who has given an admirable description of cholera and its treatment in 1832, writes thus of stimulants (*Letters on Cholera Asphyxia as it has appeared in New York*, p. 42): “We have seen no benefit from their liberal use, and it is even doubtful whether they contribute much in any quantities. It requires the conviction of experience, however, to enable us to abstain from their use, and to resist the impulse to apply them to the dying spark.”

The very general conviction as to the worse than uselessness of alcoholic stimulants in the collapse of cholera is the more to be relied upon, inasmuch as it has been forced upon men's minds in opposition to preconceived notions and prevailing theories. The action of stimulants in the collapse of cholera being obviously very different from their influence upon patients who have been exhausted by the loss of

blood-constituents, we infer that syncope and choleraic collapse are pathological conditions essentially different; and this conclusion is confirmed in a most striking manner by the effect of other modes of treatment.

The Effect of Venesection on the Symptoms of Collapse. It is scarcely necessary to assert that no sane practitioner would think of abstracting blood from a patient who has been reduced to a state bordering on syncope by any of the common sources of exhaustion which have before been referred to (p. 527). It is obvious that the loss of blood in such cases might be attended with perilous and even fatal results. But what has been the effect of venesection in not one or two, but in a large number of cases of cholera, and in the hands of many different practitioners? Has the effect of this treatment been such as to afford support to the theory that collapse results from loss of liquid? or has it been to add to the cumulative evidence which stands opposed to that theory? We will endeavour now to answer these questions.

It is in the writings of the Indian practitioners that the largest amount of evidence is to be obtained as to the influence of blood-letting in cholera. Scot makes the following remarks on this subject (*Report on Epidemic Cholera*, p. lviii). “The abstraction of blood, unless as an antispasmodic, is a remedy so little indicated by the usual symptoms of cholera, that its employment in the cure of this fatal disease has afforded a signal triumph to the medical art. It requires no common effort of reasoning or reflection to arrive at the conclusion that, when the powers of life appear to be depressed to the lowest degree, the pulsation of the heart all but extinct, the natural heat of the body gone, and the functions of the system suspended, and incapable of being revived by the strongest stimulants, the abstraction of blood might yet prove a remedy against a train of symptoms so desperate.” “Few remedies,” he says, “on a fair trial, have been more generally and unequivocally advocated than free blood-letting; and the most that has been urged against it is, that it is not always successful.” He then quotes reports from medical officers furnishing very striking testimony as to the benefit of bleeding in cases of extreme collapse.

Annesley states (quoted by Scot, p. lx):—“In place of syncope being produced by bleeding, in the cases which I have treated, the pulse has invariably improved, and the feelings of faintness and debility disappeared.”

Bell makes the following statement (*Treatise on Cholera Asphyxia*, p. 118): “The effect of blood-letting would indeed sometimes appear almost miraculous. A patient will be brought in in a cot, unable to move a limb, and, but that he can speak and breathe, having the character, both to touch and sight, of a corpse, yet will he, by free venesection alone, be rendered, in the course of half an hour, able to walk home with his friends.”

Rogers gives the following description of the effects of venesection by a medical man who was himself the patient (*Reports on Asiatic Cholera in Regiments of the Madras Army*, by Samuel Rogers, p. 259). “There was a sensation which I am at a loss to describe, as if my heart was ceasing to beat, and a dread of suffocation; this sensation was instantly relieved by bleeding, and I recovered immediately.”

The following striking case is recorded by Sir Ranald Martin (*The Influence of Tropical Climates on European Constitutions*, 6th ed., p. 349). “On visiting my hospital in the morning, the European farrier-major was reported to be dying of cholera. I

found that during the night he had been drained of all the fluid portion of his blood. His appearance was surprisingly altered; his respiration was oppressed; the countenance sunk and livid; the circulation flagging in the extremities. I opened a vein in each arm, but it was long ere I could obtain anything but trickling of dark treacly matter. At length the blood flowed; and by degrees its darkness was exchanged for more of the hue of nature. The farrier was not of robust health; but I bled him largely, when he, whom but a moment before I thought a dying man, stood up and exclaimed, 'Sir, you have made a new man of me.' He is still alive and well."

Now, let me ask, is it possible to reconcile facts of this kind with the theory that the collapse of cholera results from a loss of the liquid constituents of the blood? If Sir R. Martin's hypothetical statement, that his patient "had been drained of all the fluid portion of his blood," were an accurate expression of facts, can we conceive it possible that he could have "made a new man" of him by abstracting largely the blood which remained in the vessels? I maintain that the numerous well authenticated instances of great and immediate and permanent relief by means of venesection in the collapse stage of cholera, are utterly and hopelessly irreconcilable with the hypothesis in question.

[To be continued.]

BIRMINGHAM GENERAL HOSPITAL.

TREPHINING FOR THE RELIEF OF EPILEPTIFORM
ATTACKS, OCCURRING AFTER INJURY
TO THE HEAD.

By JAMES RUSSELL, M.D., Physician to the
Hospital.

[Concluded from p. 585.]

I HAVE now briefly to analyse the illustrations of the subject of this paper which I have been able to collect.

For obvious reasons, I exclude those cases in which convulsive attacks have occurred among the *primary* consequences of injury to the head, generally presenting themselves in union with other symptoms of concussion or compression, and being speedily removed by treatment, or issuing in early death. I may, however, note, in passing, the nature of the injury in certain cases of this description which I have preserved.

Of six cases, three were instances of more or less extensive compound fracture of the skull; two of simple fracture, or of fissure; one was without fracture. Trephining was performed in four of the cases, of which three were fatal with acute meningitis. So far as the injury which probably caused the convulsive attacks goes, it was as follows. In three, fragments of bone or a portion of skull depressed upon the surface of the brain, accompanied by laceration of the dura mater, and by superficial bruising of the hemispheres in two of the cases; in three, coagula of various extent, with superficial bruise of the brain in one case. One of the six cases may be particularised as being somewhat remarkable. There was depression of a portion of skull an inch in length, together with a

wound, from a kick by a horse. Little complaint was made until forty-eight hours afterwards, when a sudden attack of prolonged epileptiform convulsion occurred, and lasted for two hours, after which recovery went on rapidly and completely, all symptoms ceasing entirely.

Excluding, then, these cases of *primary* and *temporary* convulsive attacks, I have seventy-two other cases in which the paroxysms of convulsions must be regarded as a *secondary* consequence of the injury. I have included among them, from analogy, three cases of epileptiform insensibility merely, without convulsive action.

The period at which the attacks first manifested themselves presents the widest diversities. In some cases, the attacks have commenced immediately after the receipt of the injury, and can only be ranked among secondary consequences by their subsequent continuance; in others, on the contrary, several years have intervened. In some cases, the duration of liability to the paroxysms has been very brief, the liability being terminated by the intervention of remedial measures or of death; in others, the attacks have continued to recur through varying periods of time. In their mode of recurring, the fits have presented the same diversity as is observed in the true form of the malady. Sometimes they happen in a continuous series, though with very different degrees of rapidity; a single fit occurring at long intervals; or, as in the majority, the intervals being short, and the fits numerous. Sometimes, on the other hand, the fits return in a few widely separated but severe and protracted batches.

The period which has elapsed between the receipt of the injury and the outbreak of the convulsive fits has been as follows. On the same day in six; "early" in eleven; under five weeks in four; from five weeks to one year in twenty-one; from one year to four years in six; from four years to eight years in seven; unknown in seventeen. This wide diversity in the period which a given irritation occupies in producing a certain effect upon the nervous centres, of course admits of explanation in great measure by varying susceptibility of nervous constitution in different individuals. It is, however, a highly important fact, to be noted in passing, in relation to the natural history of epilepsy, and, indeed, of most other forms of nervous disease.

As may be supposed, when once established, there is a tendency in the fits to recur, the cause of irritation being permanent. Thus, *e. g.*, among the six cases in which the commencement of the fits was coincident with the receipt of the injury, they had continued in four for a term varying from ten to twenty years, occurring in two cases of the four with considerable frequency.

This fact also possesses considerable interest in connexion with the whole subject of epilepsy. In the cases now under consideration, the cause of the irritation is very obvious, and acts directly. We observe a cause of irritation which is in constant operation, producing, nevertheless, a distinctly paroxysmal disease; the paroxysms being instantaneous in their explosion, and complete in their cessation—in many cases even separated by a period of complete immunity, it may be of years' duration.

It is of interest to note, in relation to the same subject, that although in some instances the convulsive affections have been observed to be unilateral, yet that in the great majority, although the irritation affects only one hemisphere of the brain, it appears that the convulsions were general, and affected both sides of the body. This fact agrees with the law of reflex and convulsive action, which refers the production of the convulsions to the medulla ob-

longata. The very abundant commissural apparatus existing in that centre, which has been enlarged upon especially by Schröder Van der Kolk, would render it directly subservient to the production of bilateral rather than of unilateral spasm.

"The laws of reflex action, which have been deduced as general results from a great number of observations by E. Pfleger, are very important. In them this author shows that reflex action is at first strictly unilateral; furthermore that, if reflex action arises from a stimulus in the brain or cerebral nerves, the reflex movements, in their further progress, extend to the nerves situated inferiorly, and thus to the medulla oblongata; and that, on the contrary, if reflex action arises from a spinal nerve, it extends, in its further progress, from below upwards towards the medulla oblongata, and not *vice versa*; but that, if the affection has reached the medulla oblongata, the reflex movements may again extend in an inverse order to the lower parts, or pass into general convulsions; that, lastly, if a reflex movement arises in motor nerves which are very remote from the insertion of the sensitive nerve primarily affected, these remote motor nerves are always such as arise from the medulla oblongata. Hence it appears that the medulla oblongata is the principal centre, whence the more general reflex movements and convulsions take their origin." (*On the Spinal Cord and Medulla Oblongata*, Syd. Soc., p. 80.)

Another particular, in which a resemblance may be traced between these cases and many other forms of epileptic attack, lies in the circumstance that the degree of severity of the injury does not seem to influence the period of incubation of the fits; and, further, that incubation is not attended, in the majority of cases at least, with any nervous symptoms—such symptoms, when present, having been severe only in a few cases. Of the cases in my list in which particulars are sufficiently full, in 68 per cent. no symptoms preceded the fits beyond those resulting directly from the injury; in only 9 per cent. were the preceding symptoms severe.

Turning now to note the character of the lesion on which the convulsive attacks appear immediately to depend, we gain the following information.

In thirteen, no sufficient knowledge on the subject was attainable, or is imparted in the description, beyond the receipt of an injury, save that in one case the lesion mainly involved the trunk of the fifth pair, and in another had occasioned loss of smell and taste.

In eighteen, there was depression of a portion of the skull, including in the number two cases in which the depressed portion consisted of loose fragments after compound fracture. To this group I may add three more cases, in which a compound fracture of the skull is the only injury described, excepting that in one of the number some hair had become entangled in a fissure, and projected upon the membranes. Of the twenty-one cases which we thus obtain, ten of compound fracture are particularised; but in these ten instances the severity of the injury does not seem to have exerted a general influence in abbreviating the period of incubation of the convulsive attacks. Thus, in two of the cases, seven and eight years respectively had intervened; yet in one the fracture was extensive, and in the other the wound had remained open. In only two of the cases of compound fracture was the period of incubation so short as nine days.*

There are thirteen cases of *spicula*, of various dimensions, projecting from the inner surface of the skull. In six, the projecting portion must have been of considerable magnitude; in one, indeed, it is stated to have been half an inch, in another one inch, in length. In four, it was small; yet in one of these certainly it projected into the substance of the brain. In one case, the large projecting process was contained in a cavity in the brain of the size of a black-bird's egg, lined by a cartilaginous membrane.

An old blood-cyst, of three years' duration, had deeply impressed the surface of the brain in one case, and seemed to be the cause of the fits; and I may add that, in one of the next group, the fits seemed to have been the consequence of meningeal effusion of blood, which had taken place three months before death.

There are twenty cases in which the skull was diseased, in consequence of the original injury. The disease consisted in hypertrophy in six cases, in two of which the portion of skull was nearly three times its normal thickness; in one, the hypertrophy was accompanied by exfoliation, the whole disease being the result of trephining performed during the primary stage of the injury; in one, it was accompanied by absorption of a portion of the skull. In two cases, the disease consisted of induration; in five, of various degrees of caries; in five, of exfoliation; and in two, disease of bone was not evident, but is inferred from exquisite sensitiveness or from persistent pain.

To this group I may add five other cases which I have met with incidentally in the course of the present inquiry, in which disease of the cranial bones was induced by other causes than by injury; three of the cases being of syphilitic origin—in one with nodes from the internal surface of the skull. I may state that trephining was performed in three of the cases, and that in all three the patient recovered from the immediate effects of the operation; in one, the nervous disease was completely cured; in one, no report is given later than the close of the third week; in one, the patient died two months afterwards.

I would here advert to a conclusion which seems deducible from this group of cases of diseased bone: that disease seated in the bones of the skull is attended with greater danger of inducing epileptiform disease than when seated in other bones of the body, from causes to which allusion has been already made. The remark may, indeed, be extended with almost equal propriety to the entire class of injuries of the skull.

One group of cases yet remains to be mentioned—the cases, namely, to which Dr. Abercrombie has called attention, wherein the effects of the original injury had not penetrated more deeply than the pericranium, in some instances probably not beyond the scalp. Five cases are included in this group.

To complete the subject, it must be added that, in six cases not included in the preceding enumeration, other symptoms than convulsions resulted: insanity in two, accompanied by hemiplegia in one; hemiplegia in one, with impairment of sight, hearing, and memory; in three, fixed pain of great severity.

As the cause which produced the irritation in the cases under consideration is a permanent one, so the affection it induces is permanent also. This, which appears almost a matter of course, is amply sup-

port, and with pain in the region of the injury. This pain has never fully subsided, and its recurrence has been especially associated with the fits. He began to have fits of epileptic vertigo twelve months after the accident, having shortly before suffered from mania. Fully formed fits did not occur till eight years afterwards, and have returned at short intervals since. Twice or thrice he has had some mania. His mental powers have not suffered much permanent deterioration.

* Since these remarks were written, my friend Mr. Yates, of this town, has furnished me with the following case, under his own care. A man, aged 49, fell sixteen years ago, and had depression of the skull without wound in the occipital region. He was insensible for three weeks, and recovered with some temporary mental impair-

ported by the cases on which my remarks are based. In one case only of the entire number had liability to the convulsive attacks or other nervous disorders subsided spontaneously, and in this case the immunity is not known to have extended beyond nine months. It gives force to this statement, that in only two of the entire collection is the report defective in this particular. In twelve cases, the attacks were continuing at the date of the report; and in sixty-seven they continued either up to death or to the time when some change was effected in the condition of the cranium (or of its coverings in a few cases), either by natural processes or by operative procedure.

Out of the eighty cases, there are nine wherein death occurred irrespective of the primary effects of the injury, or of ulterior operative proceedings. The proportion of deaths has an important bearing upon the question of trephining; it is, therefore, proper to state that, of the nine deaths, four occurred in the fits, or in the subsequent coma; in two of these, no important disease was met with in the brain; in one, extensive disease, but of quite recent origin; and in the fourth, only the remains of the damage to the substance of the brain which had been inflicted by the accident. Of the other five cases, two deaths took place from causes quite unconnected with the brain; in a third, the cause was unknown; the other two deaths were occasioned respectively by diseased cerebral vessels and by meningeal apoplexy.

Of course, in estimating the force of any argument drawn from this proportion of deaths, as respects the fatal tendency of this particular form of nervous disease, it has to be borne in mind that, of the eighty cases, in sixty-six curative proceedings, natural or artificial, have interrupted the natural course of the malady. Hence it follows that, although the numbers are, of course, too few to form the foundation of any theory, they certainly justify a suspicion that the class of epileptiform disease now under our consideration has a much greater tendency to death than true epilepsy; and this suspicion is strengthened by the greater comparative frequency with which other evidences of nervous derangement attend the fits—*e. g.*, paralytic affections, mental impairment, etc. In fact, these cases closely approximate to the form of epileptic disease which is dependent upon alcoholism, or upon other influences operating immediately upon the nervous tissue.

A strong argument then in favour of trephining is afforded by the fact, that in sixty-seven cases the attacks continued up to the time when some change was effected, naturally or artificially, in the condition of the cranium or of its coverings. This change consisted in local medication in one case—ultimate result unknown; of division of the soft parts, as described by Dr. Abercrombie, in five, in all of which perfect success is stated to have followed the operation, though no data are supplied. In five, exfoliation of diseased bone took place spontaneously; in one, only partially, and with partial relief; in the remaining four, completely, and, as stated, with curative results, though again no particulars of time are afforded. These last mentioned cases, few though they be, suggest an argument from experience in favour of trephining, independently of *a priori* considerations; and we have now to learn what the experience of the operation itself teaches us.

The testimony of authors upon the subject, so far as my present examination has extended, is of a doubtful character, but appears, upon the whole, to be in favour of the operation. Mr. Syme (*Lancet*, Feb. 3rd, 1855) states decidedly that the result of his experience is opposed to it; and Mr. Solly (*ib.*, Jan. 5th, 1860), in commenting upon a case under his own

notice, gives a very qualified opinion in favour of it, alluding to the extreme severity of the operation. M. Velpeau (*ib.*, Aug. 16th, 1834) pronounces a favourable opinion, but only as regards cases in which the cicatrix is sensitive, or œdema or crepitation is connected with it. Mr. Cooper, on the other hand (*Dictionary*, art. Trephine), quotes several successful cases from a paper by Professor Dudley; Dr. Copland (*Dictionary*, art. Epilepsy) cites a considerable number of authorities who have furnished successful results, and adds other successful cases from a paper by Dr. Guild; and the writer of the article Trepanation (*Dictionnaire des Sciences Médicales*) states his opinion that the result of the operation, as performed in many instances, has justified the experiment. Finally, Mr. Van Buren (*Syd. Soc. Year Book*, 1861) regards trephining for epilepsy in a very favourable light, explaining the prevalent opinion of an opposite character by cases being selected for the operation which are fatal from their nature.

In the *American Journal of Medical Science*, July 1861, is a table by Dr. Billings of seventy-two cases in which trephining was performed for the relief of epilepsy. Sixteen proved fatal; forty-two were cured; four remained unchanged; and the remainder were improved, but were not entirely relieved. These bare statements are all which can be obtained from the record. The paper which originally accompanied the table was published originally in the *Cincinnati Lancet*, and is not here added. The table may also be found in Ranking's *Retrospect*, vol. xxxiv.

The instances of trephining amongst the preceding cases amount in all to fifty; those cases alone being included in which the operation was performed for secondary nervous disease, all instances of primary trephining being excluded.

Of the fifty cases, in forty-two the derangement originated in injury; in five, the disorders were in connexion with disease of the bone; in three, the immediate cause was uncertain. The age of the patients is given in thirty-one cases: one was eight months old; six were under puberty; twenty-four were over puberty.

Of the fifty patients, five died from the immediate effects, and one from the secondary effects, of the operation. In two of these, the operation was performed in less than three weeks from the injury; in two, in from ten to twenty months; in one, in ten years after.

Forty-four patients recovered from the operation. In these cases, the interval between the injury and the operation was as follows. Under seven weeks, five cases; from seven weeks to one year, eleven cases; from one to two years, five cases; from two to fourteen years, fourteen cases; unknown, nine cases.

The result just stated seems so much opposed to the general opinion of the danger of trephining, that it is necessary to make the following additional observations.

The total recoveries were, as just stated, forty-four out of fifty cases. In two of the forty-four, dangerous symptoms resulted from the operation, but were subdued by treatment. In five other cases, a wound or sinus communicating with a fracture of the skull remained open—a circumstance specially named by Mr. Syme as justifying the operation; and, indeed, one of these cases is given by that gentleman, in illustration of the principle just quoted. In two others, there had been a considerable loss of skull from severe compound fracture. In one, the wound had remained open for a period of nine months, though it had closed long before the performance of the operation. In ten cases, no particulars are given.

Thus there will remain twenty-five cases of suc-

cessful trephining, in which the injury had not been extensive, and in which there was no wound. Of these, eleven were cases of caries or other disease of the skull, and fourteen were instances of simple depression or of projecting spicula. In these twenty-five cases, the dura mater was healthy in nine; it sloughed in two, was perforated in five, was vascular or had pus upon it in two; its state is not described in seven.

One highly important question in relation to the operation remains—its ultimate result upon the nervous disease, for the relief of which it was chiefly undertaken. As I have already intimated, the mere removal of the source of irritation does not necessitate the cessation of the derangement, since such derangement in many cases probably involves an altered state of nutrition in the ganglion-corpuscles. For very obvious reasons, the reply to this question is very incomplete, and, unfortunately, is rendered even less satisfactory than it might have been made by the neglect of stating the length of time during which the patient remained under observation.

In nearly all the cases, the immediate consequence of the operation was to effect for a time material amendment in the patient's condition. I have given some remarkable illustrations of this statement in a former part of this paper. I add one more, as it is not only noteworthy in itself, but serves to exemplify the share which the membranes may take in generating nervous disease. The case is recorded by Dr. Hayward (*American Journal of Medical Science*, 1838, p. 517). After prolonged nervous derangement, continuing through thirteen years, the trephine was employed. A short delicate bony projection advanced from the interior of the skull; the dura mater adhered to it, but was separated by a probe without much difficulty. The membrane was quite healthy. Instantaneous and complete relief followed to the sense of pressure which the patient had felt. He declared, whilst on the table, that he had not felt so well for thirteen years; and he afterwards wrote to the operator: "The peculiar sense of relief which I expressed in the moment when the operation was over has become a part of my common consciousness."

Of the forty-four cases in which the patients recovered from the operation of trephining, in five little or no benefit resulted. One is even declared by Mr. Travers to have been worse for the operation. Satisfactory recoveries, as tested by a sufficiently protracted term of observation specially stated, amount to six. Progressive amendment had been going on through a considerable length of time in three others. Slight returns of the disease had occurred in two. In eighteen cases, cure of the disease is reported to have been effected; the terms "complete", "perfect", "permanent", being also frequently applied; but no information is given as to the duration of the observation. Finally, in ten cases the period through which the patient was watched after the operation, being stated, it is obviously too short to permit any conclusion to be drawn as to permanent results. In two cases only had the term of observation extended to three months; in all the others it was much shorter.

I may just note in passing, though doubtless the circumstance is explained by the comparative employment of the sexes, that in the cases I have been quoting, whilst eleven patients are of the female sex, fifty-six are of the male sex. The sex of the remainder is not stated.

In conclusion, I subjoin a brief account of the case which has suggested the foregoing communication.

Fanny G., aged 16, dressmaker, received a blow on the head with a coal-pick when five or six years of

age, but no symptoms of importance presented themselves in connexion with the injury. Nevertheless, the patient's mental power evidently became somewhat deteriorated in the course of time. She could not go on an errand, unless the commission was written, when it comprised more than one item. Her temper became irritable; and she was less able to apply herself than she had been. She also remained subject to severe frontal headache, but not to pain in the region of the blow.

Her first fit occurred five or six years after the accident mentioned above. In three months afterwards, the second took place; and the fits continued to recur with gradually increasing frequency since that time. They were also more numerous about the catamenial periods.

The fits were not of the most severe character, seldom passing into the fully formed asphyxial stage, though attended with general tonic and clonic spasm, and with unconsciousness; but her mental powers suffered increased deterioration since the establishing of the fits, to such an extent that I found it impossible to obtain any trustworthy information as to her history from the patient herself. Her health was good; menstruation nearly normal.

On the left side of her head, almost an inch and a half from the sagittal suture, and exactly in a line with the auditory orifice, a cicatrix existed in the scalp; and beneath it was a limited but distinct depression.

Medical treatment having been of no avail, trephining was performed by Mr. Bolton on January 9th. The portion of bone was removed without the least difficulty, and presented the small bunch of spicula figured at the commencement of this paper. The bunch corresponded to a very small opening in the dura mater.

Symptoms of acute meningitis set in decidedly on the morning of the second day, and proved fatal in three days. Right hemiplegia came on, but again diminished before death. She had repeated recurrence of severe epileptiform convulsions. From the situation of the meningitis, involving as it did the "convolution of articulate language" of Broca, it may be of interest to note that the patient never spoke from the time of the setting in of the acute symptoms; but that, shortly before her death, the nurse, thinking that she seemed more conscious, asked her if she wished to see her mother, desiring her to signify assent by squeezing her hand, she directly made the required signal; and, afterwards, a patient made the same experiment with a like result.

My friend Mr. Bolton has been good enough to furnish me with the following notes of the *post mortem* examination, as I was not able to be present.

On removing the scalp, a slight effusion of blood was observed beneath the integuments around the opening made by the trephine; and a thin coagulum also existed over the dura mater, around the puncture which corresponded to the spicula. This puncture had a jagged and sloughy appearance, from the inflammation which had followed the operation. A quantity of thin pus was found between the dura mater and the bone, extending towards the base of the skull as far as the petrous bone. The perforation of the dura mater had extended through both layers of the arachnoid membrane, and a small nipple of brain-substance projected through the opening. The arachnoid was extensively inflamed over the left hemisphere, and some sero-pus was found in the arachnoid sac. The convolutions of the left hemisphere were covered by a thin layer of the same kind of pus; but the signs of the inflammation had not extended beyond the convex portion of the hemi-

sphere. The entire substance of the brain was perfectly healthy.

I have only to add to this description, that I very carefully examined the left corpus striatum and thalamus by the microscope, comparing them throughout with the corresponding organs on the right side. I could not find the faintest traces of disease either in the tissue or in the minute vessels.

The medulla oblongata and pons were quite healthy to the naked eye. I could not trust my power of investigating their minute condition with reference to the epileptic phenomena, and therefore did not employ the microscope in their examination.

Original Communications.

REMARKS ON LITHOTRITY: WITH RECORD OF TEN CASES OF STONE.

By WALTER COULSON, F.R.C.S., Surgeon to the Lock Hospital.

LAST year I read before the Medical Society of London a paper on Lithotripsy (*Medical Mirror* for April and May 1864), containing a history of fifteen cases of stone, and such practical observations as were suggested by their treatment. It is my intention in this communication to follow the same method—to give, first, the history of all the cases of stone that have since been made under my care, and from them to draw such practical deductions as appeared to me important while the patients were under treatment. At the same time, I think this paper will be of more value in a statistical point of view, if I add two cases of calculus in children, on whom I performed lithotomy, and so complete the history of all the cases of stone that I have had under my sole charge.

CASE I. *Phosphatic Calculus: Unusually Long Urethra, with Enlargement of Prostate: Irritable Bladder: Cured after Four Sitzings.* Jan. 20th, 1864. A clergyman, from near Bury St. Edmunds, aged 70, had suffered from pain and difficulty in passing urine for the last two years. The urine was muco-purulent, and after exercise was slightly tinged with blood. He had been sounded, but no stone was detected. In accordance with my usual practice, I determined to examine him with the lithotrite on the following day; but the bladder was so irritable that he could not retain the urine during the introduction of the instrument, although he had passed water only an hour and a half before. I ordered him to keep in bed and to take a mixture containing morphia.

Jan. 23rd. Having directed that he should retain urine for two hours, I went to his house, intending to operate upon him under the influence of chloroform. In this I was disappointed, as there was reason to suppose that he was not a good subject for its administration. I selected my longest lithotrite, but found it would barely enter the bladder, and I was obliged to push the handle almost on to the pubis to allow of my opening the instrument. A calculus was then seized without further difficulty and crushed. No bad symptoms followed, and a few fragments of the triple phosphate passed. I operated again January 29th and February 1st, and finally examined him on February 16th. After this, he was relieved from all symptoms of stone, but was detained in town two or three weeks by an acute attack of rheumatic gout, consequently I had an oppor-

tunity of seeing him when all symptoms of irritation had disappeared. He continues perfectly well.

CASE II. *Phosphatic Calculus: Paralysis of Bladder: Removal of Stone in Two Operations: Symptoms Unrelieved.* Nov. 16th, 1863. Mr. H. D., aged 40, had suffered from bladder irritation for the last eighteen months. The urine contained pus, mucus, and blood, and there was incontinence at night. When he first consulted me, the least motion induced an uncontrollable desire to pass urine. His sufferings at times were most acute, and he never went longer than an hour without passing water. He had suffered from congenital weakness on one side, and the introduction of the instruments induced involuntary action of the leg on the affected side. The bladder never quite emptied itself, about two ounces always remaining after micturition.

Nov. 17th. I crushed a stone of the size of a hazel nut, and the next day he was better. There was less pain in passing urine, and less blood. On November 20th, I operated a second time, and crushed two or three soft fragments. A good deal of debris passed subsequently. The symptoms were not so much relieved as after the first operation.

I examined him frequently afterwards, but was never able to find any portion of stone, although, to make these examinations more certain, the patient was under the influence of chloroform. All the symptoms continued the same as before the operation, with this exception, that great relief was always experienced for about two hours by thoroughly washing out the bladder with lukewarm water; and this was to me an additional proof of the absence of a foreign body. At my request he consulted another surgeon, and selected Mr. Henry Thompson, who examined him four times, but with no result. He also consulted Mr. Syme, who pronounced him free from all fragments of stone.

April 3rd, 1865. I was called this afternoon to see this gentleman. All the symptoms remained precisely as they were before the operation; with the single exception to which I have alluded, the only relief he ever had from his sufferings had been for an hour or two after injecting the bladder. The urine contained blood, mucus, pus, and numberless crystals of the triple phosphate.

CASE III. *Two Uric Acid Calculi: Retention Consequent on Operation: Cured after Five Sitzings.* March 21st, 1864. Mr. W., aged 69, had suffered for some time from symptoms of stone. He first noticed blood in the urine after walking six months before. I operated March 22nd and 26th, and April 2nd and 15th, and lastly on the 23rd. The first time I found a calculus and crushed it at once. The prostate was large, and the instrument had to be considerably depressed to allow it to enter the bladder. This occasioned much pain, and at his request all the subsequent operations were performed under the influence of chloroform. There was no inconvenience experienced after the first sitting; but subsequently there was great difficulty in passing urine, almost amounting to complete retention, a few drops only coming away after minutes of painful and continuous straining. To relieve this I passed an ordinary catheter two or three times after the second and third operations. This only affording temporary relief after each of the last two, I retained a French elastic catheter in the bladder from fourteen to twenty hours, and this gave the greatest ease. This retention was, I believe, due to a little temporary swelling about the neck of the bladder and the prostate, which, in addition to the enlarged state of the gland before the operation, rendered micturition all but impossible, and also interfered considerably with the passage of fragments. He was consequently much in the same position as a patient

with paralysis of the bladder. This condition induced me to deviate from my ordinary rule, and after the two last operations, I thoroughly injected the bladder by means of a large steel catheter, which brought away a considerable quantity of *débris*. This instrument, shaped much like a lithotrite, had been made some years before by Messrs. Blaise, at the suggestion of Sir Benjamin Brodie. Mr. W. has been free from all bladder-irritation since the last operation.

CASE IV. Multiple Calculi: Frequent Operations: Continuance of Treatment: Uncured. April 15th, 1864. Mr. H. E., aged 74, had suffered for the last eighteen months from bladder-irritation. The urine was bloody and muco-purulent. He was compelled to pass a catheter (gum-elastic) four times a day in consequence of paralysis of the bladder. He had for some time past voided small calculi—as many as fourteen at a time. He stated that he had passed a thousand in addition to those now in my possession. When the calculi first came away, he had much more power in the bladder than when I saw him.

April 15th. I introduced a lithotrite, and found the bladder like a gravel-pit, literally full of calculi. It was impossible to open and close the instrument without including a fair-sized stone. The first operations afforded relief. There was great difficulty experienced in passing a lithotrite, in consequence of the engorgement of the prostate and the displacement of the urethra from a large hydrocele. I tapped the hydrocele April 26th; but the fluid reaccumulating very rapidly, I injected the sac with equal parts of tincture of iodine and water. I performed lithotripsy May 14th and 23rd, June 1st, July 12th and 23rd, October 5th, and for the last time October 28th. I was prevented from operating more frequently in consequence of the general health of the patient being very low. In little more than a fortnight after the last operation, he was seized with an attack of apoplexy. He rallied from the effects of this, but was never well enough to permit of lithotripsy being repeated, and he died in the beginning of this year. I regret that no *post mortem* examination was made. Had this been done, I have no doubt that a very large quantity of stone would have been discovered in the bladder.

CASE V. Large Calculus: Lithotripsy Attempted: Lithotomy Performed: Death from Shock. Feb. 20th, 1864. Mr. N., aged 67, from Northamptonshire, had suffered from stone for the last four years. I introduced a lithotrite, and attempted to crush the calculus, but found this impossible, as the bladder could not retain sufficient urine for the instrument to be opened wide enough to admit so large a stone. Although the patient was kept quiet in bed and the attempt was repeated, it was unsuccessful. I performed lithotomy on March 1st in the presence of Dr. Broadbent, Mr. Armstrong Todd, Mr. Evans, etc., and removed a stone weighing 5 viii ℥iiss. The patient died on March 3rd from the shock.

CASE VI. Large Calculus: Lithotripsy Impossible: Lithotomy Performed: Death from Secondary Hemorrhage. Mr. H. W., aged 30, from Ramsgate, consulted me July 7th, 1864. His symptoms were those of stone; but he had been recently sounded, and none had been detected. I directed the patient to keep quietly in bed, and to retain the urine an hour and three quarters before my visit. On introducing the lithotrite, it at once came into contact with a large stone, which I found it impossible to seize. In my first attempt to do so, the urine escaped with a rush along the urethra. After keeping him in bed for a few days I made a second attempt, but with the same result. Accordingly I determined to perform lithotomy; and, on July 20th, in the presence of Mr.

Coulson, Mr. Evans, Mr. Cooper, Mr. Scott, and Mr. Peacock, I removed without difficulty a large stone weighing 19 drachms. He passed a good night, and the next day was remarkably well. There was some hemorrhage in the afternoon that the nurse arrested without difficulty. The bleeding recurred in the night, when I was unfortunately from town. A physician of large experience saw the patient; and, the bleeding having apparently ceased, he did not think it necessary to plug the wound, but contented himself with ordering a pill containing a grain of opium. An hour afterwards the bleeding returned, and Mr. Cooper saw him and plugged the wound. He ordered stimulants, but the bladder was filled with clots of blood, and the patient died early on the morning of July 22nd, from secondary hemorrhage.

CASE VII. Small Uric Acid Calculus: Two Sitzings: Cured. Mr. F. T., aged 57, noticed blood in the urine the beginning of October 1863, after a day's shooting. He was sounded twice in Aberdeen and once in Edinburgh, but no stone was detected. Driving or railway travelling induced pain along the urethra. I first saw him October 31st, 1864. On November 1st, I examined him with a lithotrite, and crushed a small stone with no unfavourable result. On November 7th, at his own request, I performed the second operation under chloroform, as he was anxious, if possible, to have all fragments removed. To accomplish this, I used the scoop, introducing it twice, and each time bringing away *débris*. The patient passed some fragments after each operation. Ten days after the last sitting, he left town perfectly well.

CASE VIII. Small Uric Acid Calculus: Lithotripsy: Two Sitzings: Kidney-Disease: Death. Feb. 25th, 1865. W. W., aged 54, market-gardener, had passed several small calculi during the last twenty years. These appear to have descended from the left kidney, as before passing them the urine was bloody, and he suffered acute pain along the course of the left ureter. For several weeks past he felt sure there was a stone in the bladder, too large to come away. On February 25th, I crushed a small stone, and no bad symptoms followed. On March 1st, I crushed the remaining fragments in the presence of Mr. Cooper. The next day some few fragments passed, the urine was scanty, and there was increased bladder-irritation. On March 3rd, he had passed a bad night, and had no appetite. Pulse 100 and weak; tongue dry. He had had no shivering fit, but there was a general tremor, as if he were suffering from extreme nervousness. He also complained of difficulty in passing water, pain in the back and over the region of the bladder. The urine continued scanty, was much clouded, and of a deep saffron colour. On examining the urine under the microscope, there were a large number of epithelial casts with blood corpuscles entangled in them. Dry cupping over the region of the kidney and all other treatment proved equally powerless in arresting the disease. The patient died March 9th, of acute nephritis, nine days after the last operation.

The following are the histories of the cases of the two children, to which I have alluded.

CASE IX. In the early part of 1861, I performed lithotomy on a child aged 2, and removed a small mulberry calculus. The child was cured.

CASE X. Oct. 16th, 1861. Charles Davy, aged 11, had been suffering for the last two years and a half from pain and difficulty in passing water. Not unfrequently the bowels acted involuntarily in his effort to pass water. On October 17th, I performed lithotomy, and removed a fair sized stone. The boy was cured.

The following is a brief *résumé* of all my cases of stone.

	Total.	Cured.	Uncured.	Died.
Lithotomy.....	6	3	—	3
Lithotriety.....	19	16	2	1

In my paper of last year, I entered into the relative value of some of the symptoms of stone, hæmorrhage, pain, the mechanical effects of a foreign body, and the secondary consequences of its presence; viz., inflammation with muco-purulent urine, etc. After describing the operation of lithotriety, and stating that I examined with a lithotrite as the most certain means of detecting stone, the following were my conclusions on some points in connection with the operation:—That preliminary injection was rarely necessary; that the quantity of fluid in the bladder offering the greatest facility for manipulation was about four ounces, but that less would suffice if the larger quantity was a source of uneasiness; that at the first sitting it was not prudent to crush the stone more than once or twice; that no rule could be laid down as to when the next operation should be performed, as this must depend entirely on the symptoms of the patient; that the first operation and its results formed a guide to the after-treatment, and that at subsequent sittings the instrument might be kept in the bladder five or six minutes, and in that time many fragments might be crushed; that the forcible removal of fragments through the urethra was not only inexpedient, but always a source of danger.

The following is among the questions which have since occurred to me as worthy of consideration.

Is it advisable to operate at once without first preparing the patient by the preliminary introduction of instruments?

M. Civiale, in his *Traité Pratique et Historique de la Lithotrite*, devotes several pages to the *préparation locale* and the *traitement préalable* in lithotriety. No doubt the urethra does, in most cases, become less sensitive by the preparatory introduction of instruments; but in my opinion, what is gained in one way is lost in another. The only point, therefore, which I care to ascertain, is whether the calibre of the urethra is sufficient to admit the introduction of an instrument. There is not absolutely any great difference in the degree of pain occasioned by an ordinary sound and by a lithotrite. Believing, as I do, that no instrument, save a lithotrite, will infallibly detect the presence of a stone, I invariably employ it at my first examination in preference to an ordinary sound. And I am sure that most persons would infinitely prefer suffering a little more pain in the first instance, to enduring the nervous anxiety attendant on the repeated introduction of instruments, together with the dread of an operation, which they imagine more dangerous and painful than it really is. By adopting preliminary treatment, the aggregate amount of pain is materially increased; besides which it is always a great source of comfort to the patient to know that the disease has been treated as soon as discovered, and the calculus crushed at the first examination. The plan I adopt enables him to look forward to successive operations without unnecessary dread.

In Case No. 3, in consequence of the enlarged condition of the prostate and the irritation produced by the introduction of the lithotrite, the patient suffered all the agonies of repeated retention. He experienced the greatest relief from retaining an elastic French catheter in the bladder after the operation. The great merit of this instrument, which is far superior to those made in this country, consists in its smoothness and pliability, which enables it to be kept for hours in a bladder loaded with débris without exciting the least irritation. The presence of a

silver catheter would confine the patient to one position in bed, and its retention in the bladder would cause increased pain. Should I ever be so unfortunate as to lacerate the urethra either in introducing the scoop, or withdrawing it when too full of débris, I should in that case retain this kind of catheter, so as to enable the inflammation about such a wound to subside before the urine and fragments were allowed to pass over the lacerated surface; for it is in these cases of laceration and these alone, as far as my experience goes, that there is any trouble from the impaction of fragments in the urethra.

In the discussion which followed the reading of the paper, alluded to at the Medical Society last year, the question was raised whether lithotriety, as performed by M. Civiale, is applicable to cases where there is so-called paralysis of the bladder. For such cases, one of the highest authorities in this country has recommended the removal of small calculi or the fragments of large ones *en masse*. This practice is not only directly opposed to that of M. Civiale and the late Sir B. Brodie, but occasions considerable and unnecessary suffering, and is also attended with great risk from extravasation. I prefer prolonging each sitting, introducing the scoop or non-fenestrated lithotrite more than once, and on each occasion pulverising the fragments as much as possible, and removing a little débris. Subsequently, but only in cases of paralysis, I should introduce the steel catheter, to which I have alluded, and should wash the bladder thoroughly out after each operation.

IMPERVIOUS STRICTURE OF THE URETHRA, AND ITS TREATMENT.

By WILLIAM ALFRED ELLISTON, M.D., Surgeon to the Workhouse Infirmary, etc., Ipswich.

At a time when stricture of the male urethra, in its different stages, is the subject of considerable discussion in the columns of the various medical journals, I venture to hope that the records of the subjoined cases may be interesting to the profession, as illustrating a course of treatment from which I have seen the best results in my own practice, and in the wards of Guy's Hospital; and which, moreover, I believe to be superior to any operation yet suggested for the relief of impervious strictures in or anterior to the membranous portion of the canal.

The operation is in great favour with Mr. Cock. I do not think, however, that he has published the results of his cases; but I believe they have been most favourable.

It is performed thus. The patient being tied in the lithotomy position, and brought to the edge of the table, the left forefinger of the operator is introduced into the rectum, and the anterior edge of the prostate felt for. A long and narrow scalpel should then be plunged into the perinæum by the right hand of the operator, about half an inch in front of the anus, care being taken not to wound the rectum; the knife may be carried upwards from the prostate in the median raphe of the perinæum. In this way the urethra may usually be punctured without much difficulty, owing to the distension of the canal posterior to the stricture by the retention of the urine. As soon as the urethra is punctured, a female silver catheter, with the tapes applied, should be as quickly as possible passed into the bladder and secured. No staff is required. Mr. Cock thinks a staff is apt to mislead the operator; he thinks it best to trust to one's anatomical knowledge to hit the urethra, which, with the introduction of the catheter, are the main points of the operation. In a deep pe-

rinæum, these may both be matters of considerable difficulty.

The object of the operation is two-fold: to evacuate the bladder, and to promote the absorption of the stricture itself. It is a matter of experience, that almost all strictures will relax if the bladder can be evacuated by any artificial means. This operation is, therefore, an admirable illustration of the influence of rest in the treatment of disease as instanced in Case II, reported below.

The greatest care and attention are required in the after-treatment. The female catheter should be retained at least three or four days; attempts being made daily, or rather at the discretion of the surgeon, to introduce a catheter—not too small a one—through the stricture. Usually this will be accomplished in four or five days; the time required may, however, be much longer, as in Case II. It is essential to keep the artificial opening in the perinæum quite patent by the daily introduction of a female catheter, until a catheter can be introduced through the stricture into the bladder.

This operation, therefore, is comparable in its adaptation to practice, to the older and more generally preferred operations of puncturing the bladder *per rectum* or *supra pubem*. Excepting in those cases where the obstruction is in the prostatic portion of the canal, I think that this operation has this great advantage over puncture of the bladder, that, in the event of the stricture proving impermeable, an artificial urethra is established, and the patient has perfect control over his urine, instead of a fistulous opening into the bowel or through the abdominal walls.

It differs considerably from the operation of perinæal section suggested by Mr. Syme; as he passes a staff down to, and if possible through, the stricture, and divides it. In this operation, no staff is required, and the stricture is not divided. I will not presume to say that, in all cases, this operation will supersede the necessity for the division of the stricture (which I must regard as a more dangerous operation); but I believe that there are few cases indeed which might not be made amenable to treatment without the division of the stricture, at any rate from the outside. I think, however, there can be no question that, assuming that the urethra may be dilated to its original size and kept so by mere puncture, we get a vastly superior urethra to what we do in those cases where it has been deemed necessary to resort to the division of the stricture.

CASE I. *Old-standing Stricture and Fistulous Openings, with Occlusion of the Natural Urethra. Establishment of Artificial Passage.* David Cook, aged 57, was admitted into the Infirmary of the Ipswich Workhouse, Nov. 7th, 1864.

The history of the case was briefly this. About sixteen years since, he first had symptoms of retention of urine, for which he consulted a surgeon in the country, who failed to introduce a catheter. Infiltration followed, and the surgeon made an artificial opening towards the distal end of the penis into the urethra; since which the meatus urinarius had been occluded. He seemed to have passed urine tolerably well through this artificial opening for some years. During the past three or four, however, micturition had been both difficult and painful. He consulted several medical men, and was for some time out-patient at a county hospital. But, inasmuch as catheterism was impossible, matters became gradually worse. About fourteen days previously to admission, the urethra gave way. Infiltration occurred; and fistulous openings broke out in the penis, scrotum, thighs, and above the pubes. Suppuration supervened.

Upon admission, he was much emaciated and collapsed. He complained of shivering fits, and seemed likely to sink rapidly. The urine was dribbling away unconsciously, mixed with pus, from the fistulous opening. The penis and scrotum were infiltrated and swollen to an enormous size. Both the original meatus and the artificial one were impermeable to catheters. He was at once ordered a generous diet; but no alcoholic stimulants were allowed.

Nov. 30th. He had somewhat revived; and I suggested to him the propriety of submitting to an operation. To this he willingly agreed; and to-day, after consultation with Dr. J. H. Bartlet, and with his kind assistance, I incised the perinæum, punctured the membranous part of the urethra, and introduced into the bladder a female silver catheter, which was properly secured and left for three days. Free incisions were at the same time made in the penis and scrotum. He was ordered brandy and egg mixture, in addition to a full generous diet.

In a week's time, he was very much better. The wounds were granulating; and the penis and scrotum were much reduced in size. He could control his urine for half an hour at a time, and expressed himself as much relieved by the operation. Albumen was present in the urine in small quantities; but it was thought to be due probably to the admixture of pus. The female catheter was regularly introduced every day through the new urethra for some weeks, in order to establish a permanent passage. His bladder being in a state of chronic cystitis, he experienced much relief from the injection of warm water and morphia. He continued to convalesce for nine or ten weeks. The fistulous openings discharged but little. He had perfect control over his urine, which he could then hold for two or three hours. He was able to sit up, enjoyed his food, and seemed fast recovering.

About the end of February, he had some unfavourable symptoms; he vomited occasionally, fell off his appetite, and became much emaciated. The fistulae again discharged profusely. He became gradually weaker; and I imagined him to be sinking from disorganisation of the kidney.

March 28th. He was becoming weaker daily and more emaciated. The fistulae discharged pus profusely. It was satisfactory to remark, that he had perfect control over the evacuation of his bladder, and could hold his urine two or three hours at a time. A permanent artificial urethra was established in the perinæum, through which I easily, this day, passed a female catheter.

April 7th. He died yesterday.

Autopsy. At the autopsy this day, kindly performed by Dr. Moore, we found the bladder very small, and the coats much thickened. A capital and capacious passage had been established between the bladder and the perinæum through the membranous part of the original urethra, now a mere *cul-de-sac*. To our great astonishment, we found the kidneys and ureters perfectly healthy. The heart and other important organs were equally normal. There is little doubt, therefore, that, had this operation been done earlier, the man's life might have been spared for some years. The large amount of sloughing in the different fistulae was too much for even an unusually good constitution; and, in the absence of any pathological change in any of the important organs, it may, I think, be fairly presumed that exhaustion was the sole cause of his death.

CASE II. *Impermeable Stricture of the Urethra: Puncture of the Urethra behind the Stricture: Successful Result.* William Farthing, aged 42, was admitted into the infirmary of the Ipswich Workhouse, the latter part of December 1864.

His previous history was that he had been troubled on micturition for fourteen months past, which occurred three months after, and was probably consequent upon, a somewhat severe gonorrhœa, concerning the treatment of which it would be well to remark, *en passant*, that no injections were used. Catheterism was attempted by the medical officers of Her Majesty's ship *Nile*; subsequently in hospital, by Deputy-Inspector-General Salmon; it was found, however, to be impossible to introduce a catheter of any shape or form; and, in consequence of the impermeable nature of the stricture, he was discharged from the navy on March 18th, 1864.

On admission, he could pass no stream. His urine dribbled away by drops, causing great pain. I found a tight stricture in the bulbous portion of the urethra, which was pervious to a No. 4 silver catheter; and another in the membranous portion of the canal, quite impermeable. Here the instrument diverged into false passages, and gave rise to some little hæmorrhage. He was ordered alkaline medicine with large doses of tincture of benbane. Attempts were repeatedly made by myself and some medical friends, to introduce a catheter under the influence of large doses of opium, the warm bath, and chloroform; but all to no purpose. I accordingly suggested to him the necessity of an operation, to which he willingly assented.

Jan. 15th. After consultation with and with the kind assistance of Drs. Bartlet, senior, and H. G. Moore, he was placed under chloroform. I punctured the membranous portion of the urethra (which was considerably distended with urine) and introduced a female silver catheter through the wound, inwards into the bladder. A large quantity of urine was thus drawn off, and the catheter was firmly secured. He was ordered to have a generous diet, and to take two grains of opium at bedtime.

Jan. 16th. He was very comfortable. The urine had passed freely through the catheter. Attempts to pass a catheter by the natural passage failed.

Jan. 17. I again endeavoured to pass a No. 6 silver catheter, but this instrument diverged into a false passage, and induced such profuse hæmorrhage, that I determined to try no more for some days to come.

Jan. 18th. The female catheter was removed.

Jan. 19th. Urine had passed freely through the opening in the perineum. The female catheter was introduced and removed.

Jan. 20th. I again attempted to pass a good sized catheter through the stricture, and again induced profuse hæmorrhage, which saturated the bed. I introduced the female catheter through the wound in the perineum, and, having some difficulty in passing it, let it remain.

Jan. 22nd. The female catheter was removed.

Jan. 23rd. The female catheter was introduced and removed.

Jan. 24th. This was the eleventh day since the operation. He was passing his urine freely, and with control, through the perineal opening. To-day, I introduced a No. 8 silver catheter slowly and steadily through the first stricture, and after about ten minutes of gentle but firm pressure upon the hitherto impermeable stricture in the membranous part of the canal, I had the satisfaction to feel the stricture gradually giving way. The catheter slowly glided into the bladder, and was there retained.

Jan. 29th. The catheter was removed.

From this time an instrument was introduced daily. By February 10th, the wound in the perineum had healed, and he passed his water freely and without difficulty by the natural passage. Warm baths were used twice daily.

March 22nd. He could now pass as good a stream as ever. For the last fortnight he had been able to introduce a No. 8 instrument for himself, which he had done every other day. To-day I passed a No. 10 catheter without any difficulty; and, being anxious to return to Woolwich, he was discharged cured.

Reviews and Notices.

OPTICAL DEFECTS OF THE EYE, AND THEIR CONSEQUENCES, ASTHENOPIC AND STRABISMUS. By JOHN ZACHARIAH LAURENCE, F.R.C.S., M.B. Univ. Lond., Surgeon to the Ophthalmic Hospital, Southwark; etc. Pp. 109. London: 1865.

THE term "Optical Defects of the Eye" may to many appear tautological; inasmuch as it may be said that all defects of the organ of vision are necessarily optical. Mr. ZACHARIAH LAURENCE, however, uses the term to denote the defects of vision which depend on irregularities in structure or function of the parts of the eye concerned in vision (*ὀψις*), in contradistinction to injuries and other pathological lesions of the eye itself (*ὀφθαλμος*), which come within the province of ophthalmic medicine and surgery. The optical defects of the eye are, in short, those which require for their comprehension and treatment an acquaintance with the physical laws of vision, and with the manner in which such knowledge may be applied to the artificial correction of these defects. Such is the instruction which Mr. Laurence here endeavours to impart in as simple a form as the subject will admit, and at the same time with sufficient detail to give the student of optical defects a good starting point for observation.

The remarks here offered by Mr. Laurence are, as he states in the preface, founded on the information which he has derived from a study of the writings and labours of the distinguished ophthalmologists, Donders, Snellen, Mackenzie, Giraud-Toulon, Von Gräfe, etc., as well from his own experience. They were originally imparted in the form of lectures at the Southwark Ophthalmic Hospital; but are here arranged in ten chapters, as follows. 1. Optical Considerations; 2. Physiological Optics; 3. Pathological Optics; 4. Myopia; 5. Hypermetropia; 6. Astigmatism; 7. Presbyopia; 8. Paralysis of Accommodation; 9. Asthenopia; 10. The Connection between Convergent Strabismus and Hypermetropia.

In the first chapter, Mr. Laurence gives such an outline of pure optics as is necessary for the understanding of the optical construction and defects of the eye.

In the second, the author treats of the optical structures of the eye in their physiological relations. The phenomena of accommodation is explained, and the different theories of its mechanism are given. Mr. Laurence states that the chief instrument of accommodation is the ciliary muscle; but that the iris acts as a supplementary organ. It contracts when we view near objects; dilates when we look at distant ones. He believes that

"The contraction of the pupil is intended as a corrective supplement to our accommodation, properly so called" (increase of convexity of the crystalline) "by diminishing any slight circles of diffusion in the

external image that might possibly arise from inaccurate contraction of the ciliary muscle."

But the action of the iris in accommodation is, as we understand the author, unimportant in comparison with the action of the ciliary muscle; as may be shown by placing before the eye a thin plate of metal or a card perforated with an aperture equal to the smallest size of the natural pupil.

The chapter is concluded with some remarks on binocular vision and the phenomena of the stereoscope.

The third chapter, on Pathological Optics, is merely a short one introductory to the study of optical defects. Its object is to introduce to the reader a system of classification adopted from Professor Donders, and founded on the refractive condition of the eye in the state of rest. The system is shewn in a table.

In the fourth chapter, the author commences by discussing a subject which he purposely omitted in the first—that of concave lenses. He then goes on to speak of myopia, commenting on the characteristics of this defect given in the preceding table. The far point—the farthest point which can be focussed again on the retina by the refractive power of the eye—he has found to vary from (in extreme cases) $\frac{1}{16}$ English inch to 80 inches from the cornea.

Having given directions for ascertaining the presence of myopia and determining its degree, Mr. Laurence shews that the distance of the farthest point of distant vision cannot always be taken as the focal length of the concave glass with which he should be supplied; e.g., in practice it is found that a maximum far point of six inches requires, not a $5\frac{1}{2}$ -inch or 6-inch glass, but a 7- or an 8-inch one. This arises in part from the fact that, in viewing the test-subject at six inches, the eye had undergone accommodation, so that the increased convergence of the crystalline lens requires to be neutralised by the concave lens.

At page 44, Mr. Laurence refers to a "dazzling" appearance on objects of which persons having a high degree of myopia complain when fitted with glasses. He states that he has found this remediable by simply tinting the glass.

"This appears to me to prove that the sensation alluded to has its origin in some hyperæsthetic condition of the retina to light. The only direct evidence I have to advance in favour of this hypothesis is, that I have never seen any of the highest degrees of myopia unaccompanied by morbid alterations of the fundus oculi (staphyloma posticum) but once; and in this instance—a myopia of $\frac{1}{16}$ —the patient wore a 2-inch uncoloured concave glass without any inconvenience."

On the other hand, Mr. Laurence has met with high degrees of myopia with extensive staphyloma posticum in which dazzling was not produced; hence some further explanation than that which he has offered appears to be required.

Having given formulæ for the determination of the far point, Mr. Laurence cautions against supplying a myopic patient with glasses that will oblige him to use the entire accommodating power of the eye, and thus exhaust the ciliary muscle. Clinical experience, he says, must here correct our calculations; but, as far as rules can be laid down, the following should be attended to.

"1. If little or no accommodation exists, give a

glass which entirely supplants any slight retinal accommodation still present. 2. If a moderate amount of accommodation exist, give a glass which partially supplants this natural accommodation. 3. If perfect accommodation exist, the same glass that does for distant will do for near objects." (P. 48.)

He then goes on to describe two diagnostic signs of myopia; viz., great length of the antero-posterior axis of the eye; and the detection by the ophthalmoscope of myopic refraction and staphyloma posticum.

In the fifth chapter, the author discusses Hypermetropia, commenting in order on the characteristics of this affection, and adducing cases and giving directions as to the use of glasses.

In the sixth chapter, Astigmatism is described; and in the seventh, Presbyopia.

The eighth chapter is a reprint of a paper on Paralysis of Accommodation, published in the first number of the *Ophthalmic Review* by Mr. R. C. Moon, under Mr. Laurence's superintendence. The chapter contains some interesting observations of the effects of the Calabar bean on cases of the class alluded to.

In the ninth chapter, the author speaks of Asthenopia; and in the last, of the connection between Divergent Strabismus and Hypermetropia.

Mr. Laurence is well known to have carefully studied the pathology of vision according to the light which the most recent researches have thrown on it. He is therefore thoroughly qualified to give instruction to others; and, moreover, shews in this book that he possesses the power of placing his knowledge of the subject before the profession in well condensed and easily comprehensible language.

THE WARD MANUAL; OR, INDEX OF SURGICAL DISEASES AND INJURIES. Arranged by THOMAS W. NUNN, Surgeon to the Middlesex Hospital. London: 1865.

THIS is a tabulated catalogue of the various forms of disease and injury which may come under the notice of the surgeon, arranged according to regions. Its purpose, Mr. NUNN tells us, is to afford the clinical student a means of constantly testing his acquirements; of enabling him to learn at a glance what he has seen, and how much still remains for him to see. The *Manual* is intended to be used by the student in the hospital ward, where he is to note down in it any example of injury or disease that may occur to him, and on returning home write out the particulars in his note-book.

The author has also appended a chapter on Inflammation, Cancer, Syphilis, and other diseases with which the surgeon has to deal.

Mr. Nunn's plan may be fairly considered as one of those which students may find of use to them in their clinical studies.

STAMMERING AND STUTTERING: THEIR NATURE AND TREATMENT. By JAMES HUNT, Ph.D., F.S.A., etc. Sixth Edition. Pp. 273. London: 1865.

THIS new edition of a well known work requires no introduction beyond the announcement of its appearance. The author, in the preface, specially urges on the public the importance of early treatment of all cases of defective speech, especially in children.

British Medical Journal.

SATURDAY, JUNE 17TH, 1865.

THE COMING ELECTION OF COUNCILLORS.

NOTHING could more plainly demonstrate the false position held by the Council of the Royal College of Surgeons as now constituted, than the nature of the forthcoming election of Councillors. An ordinary spectator would suppose, that the main object of all those gentlemen who are candidates for a seat in the Council must be to become Councillors. But it is nothing of the sort. Their main object is to become Examiners. *Hic labor, hoc opus est.*

If, indeed, Examiners were excluded from a seat in the Council, and were elected according to merit from the whole body of Fellows, in accordance with the terms and the spirit of the College Charter, how many, we might ask, of the present candidates would appear in the field, seeking entrance into the Council?

The truth is, that very few Fellows enter the Council as Mr. Paget of Leicester did, and as Mr. Turner and Mr. Charles Hawkins will, if elected, solely for the purpose of assisting in the management and direction of the affairs of the Corporation.

We appeal to the conscience of Fellows—candidates for office themselves—if it be not literally true, that most of those who come forward for seats in Council, do so against their own wishes, and to their personal inconvenience; and solely because they are forced to pass through the Council Chamber in order to obtain the prize to which they may be justly entitled, and which is the object of their desires and ambition—an Examinership.

Then, again, the qualifications for a good Councillor and the qualifications for a good Examiner are very different. A man may make an excellent Councillor, and yet be a very indifferent Examiner; and *vice versa*. Indeed, the very qualifications which render a man a perfect Examiner may make him less fit for the duties of governing the Corporation. Age, too, which may make a man a good Councillor, as a rule, must render him less apt as an Examiner. Be this as it may, however, it is evident enough, that going through a course of Councillorship can in no way improve a man's powers as an Examiner.

The election now before us illustrates in a remarkable manner the truth of all this. Mr. Paget and Mr. Prescott Hewett, at the last moment, and with evident reluctance, have come forward as candidates for the Council. Both their names stand a few months before Mr. Charles Hawkins's on the College list of Fellows; and, in accordance with what we

conceive to be a very mistaken rule of seniority, Mr. Hawkins, before coming forward, ascertained that they did not mean to offer themselves as candidates. Why, then, have they both so suddenly altered their minds? Well, we suppose, the only possible explanation of the fact is to be found in the suggestion made above. The anomalous and absurd system adopted by the College authorities has satisfied them that they will never gain admittance into the Court of Examiners unless they previously serve the office of Councillor, for which, as we suppose, they have little inclination or vocation. But why, it may be asked, were not Mr. Paget and Mr. Hewett long ago elected (as they ought to have been) Examiners of the College? Indeed, some years since, as some of our readers may remember, we especially instanced Mr. Paget as a Fellow signally fitted to be an Examiner, and spoke of his non-election as a fact condemnatory of the Council. Now why should these two Fellows, for example, be forced into a situation for which they have, as we suppose, no inclination; and so (possibly) prevent the entrance into the Council of Mr. Charles Hawkins, who has not only a decided inclination to undertake the duties of Councillor, but who would (in the opinion of all who know him) make a most admirable Councillor? Why, in the name of common sense, should the services of a notoriously independent and excellent man of business, of one who is thoroughly master of the whole College system, and who views, and has ever viewed, it from the most liberal aspect, who is no new convert to the strongly rising and urgent spirit of the times, but who has always advocated reform principles—why should such a man's services be lost to the College, or rather to the whole profession, merely because the Council insist on evading the spirit of their Charter, and will not elect excellent Examiners merely because they are not members of the Council?

Now, the truth is, that the Charter is evaded; and that men like Mr. Paget and Mr. Hewett (not being of the Council) are not elected Examiners, simply because men of the independent stamp of Mr. Charles Hawkins and Mr. Turner are not on the Council; and therefore it is that we still urge on the Fellows the election of Messrs. Turner and Hawkins. We will venture to say that their election would be a declaration of immediate reform in the Council—would be very soon followed by the admission into the Court of Examiners of men like Mr. Paget and Mr. Hewett, though not members of Council.

The plea that Mr. Hawkins should give way to Mr. Paget and Mr. Hewett as candidate for the Council, because he happens to be junior on the College-list, is one to which we take a very strong objection. It is high time that the College-list position of seniority, and the fact of a man being a hospital surgeon, should cease to be deemed neces-

sary qualifications in a candidate for the Council. The wise thing for the Fellows to do is to take the best man who offers himself; to accept the man who, it is certain, will fulfil his promises when in office, and who has not suddenly become a liberal on the eve of his office-seeking. It is quite time the notion that Fellows have a sort of right to entrance into the Council, according as their names stand on the list, should be done away with. The Council was not made for the benefit of a few senior Fellows; but the Fellows are elected to the Council for the benefit of the College.

As regards the coming election, we may observe, that the profession seems to have determined that neither of the retiring-by-rotation Councillors—Mr. Quain and Mr. Shaw—shall be re-elected; and that there is a third vacancy, resulting from the retirement of Mr. Arnott. And for these three vacancies there are the following candidates, given in chronological order, according to the dates of their admission as members:—Mr. Turner, May 3, 1816, and Mr. Ransome, of Manchester, October 5, 1827.—Mr. Quain, January 18, 1828; Mr. Shaw, September 12, 1828; Mr. Erasmus Wilson, November 25, 1831; Mr. Ure, November 7, 1834; Mr. Paget, May 13, 1836; Mr. Hewett, July 15, 1836; Mr. Charles Hawkins, March 3, 1837. All these gentlemen were admitted Fellows on the same day, December 11th, 1843, with the exception of Mr. Ransome, who was admitted on August 26th, 1844. It will thus be seen that Mr. Holt has retired. We shall not play the part of *Vates* or *Argus*, by pretending to guess who, out of so many runners, will be the successful winners; but we shall content ourselves with recommending the election of Mr. Turner, because he is a country Fellow, and a most proper representative of the country Fellows; and the election of Mr. Charles Hawkins, because we believe there is not a man on the list of the College Fellows whose election would be of greater service to the best interests of the Royal College of Surgeons of England; and we sincerely trust that Mr. Hawkins will not be induced to withdraw his name through any (as we think) erroneous idea of punctilio in reference to seniority.

TYPHUS AND SMALL-POX IN LIVERPOOL.

THE Annual Report of the Health of Liverpool for 1864, recently issued by Dr. Trench, is a valuable contribution to the records of sanitary science, containing an accumulation of facts and figures bearing upon the health of towns which are of more than local interest. The history of the typhus epidemic naturally occupies the most prominent position in it. The direct effect of an epidemic in augmenting the ordinary mortality of a community is clearly brought out in this Report. We find, for instance, that the total

number of deaths from all causes in Liverpool during the year 1864 was 16,836, or 1,626 above the average of the preceding ten years; and that, during the same period, typhus accounted for 1,740 deaths, or very nearly the exact excess of mortality for the year.

The varying influence of typhus on the death-rate in epidemic and non-epidemic times is exemplified thus. In 1860—a non-epidemic year—the typhus death-rate was, it appears, about 3 per cent.; in 1862, when the epidemic commenced, it was 5.2; in 1863, 7.6; and in 1864, when at its height, 10.5 per cent. of deaths from all causes.

The ratio in which typhus contributed to the mortality, as compared with other zymotics, was as follows. The total zymotic deaths for the year were 4,870 (or 28.9 per cent. of deaths from all causes), of which typhus accounted for 1,740, or nearly one-third; diarrhoea caused 847, small-pox 482, hooping-cough 370, scarlatina 349, and measles 368.

The Report goes into the alleged causes of epidemic typhus. Assigning a certain subordinate value to contagion modified by atmospheric influences, to overcrowding, filth, and drunkenness, Dr. Trench appears to have arrived at the conclusion that the essential cause of this epidemic was “indigence”—*i. e.*, an increased amount of privation amongst that class of the community upon whom the chief incidence of typhus fell. In this respect his conclusions differ from those of Dr. Buchanan, the Government Inspector, who could not trace that close connexion between typhus and destitution essential to constitute the relation of cause and effect. The different results arrived at by two independent inquirers may be to some extent explained by the different data upon which each proceeded in determining the amount of destitution existing in the town. Dr. Buchanan adopts, as a standard of the extent of poverty, the returns of parochial relief for the parish; and, taking these as a test, we certainly, in general terms, arrive at this result—namely, that when distress was at a maximum, fever was at a minimum; and *vice versa*. It is also worthy of note that the Registrar-General, in his Report for the third quarter of 1864, shows that throughout the country, when pauperism had declined and provisions were cheap, the epidemic had attained its greatest activity; and that the general mortality of the country was at the same time much above the average, indicating that epidemic disease is ruled by some cause apart from destitution. Again, it is remarkable that, during this entire epidemic, relapsing or so-called famine-fever has not made its appearance. Dr. Trench, however, does not accept parochial relief as the chief and only test of indigence, but bases his calculations to a considerable extent upon the records of charitable institutions, and also takes into account the effects of prevailing sickness as necessarily productive of much distress

which does not make itself apparent in the parish registers; and he, therefore, hesitates to accept an opinion very generally entertained, "that there is no more reliable test of the prevailing destitution than the fluctuations of the out-door relief-list."

During the present epidemic in Liverpool, besides other persons who have contracted the disease in the discharge of their duties, six medical men have fallen victims to the fever, among whom were two district medical officers and two house-surgeons.

The parochial authorities of Liverpool have, we are glad to hear, built a new Fever Hospital, consisting of eight wards, in four stories. Each ward contains twenty beds, is ventilated by opposite windows, and gives 1,100 cubic feet to each patient. The wards communicate at each end with a shaft extending from the top to the bottom of the building, containing the staircase, and thus affording ready means of exit in case of fire. There has been no extension of fever in the neighbourhood of the hospital, no cases of typhus having occurred in the closely inhabited adjacent workhouse, except such as could be traced to direct communication with the fever-wards.

The importance of isolation and efficient ventilation is made strikingly apparent by comparing the arrangements just described with the state of matters in one of the out-township workhouses. In the West Derby Union, typhus cases, at the time of Dr. Buchanan's inspection, were treated in buildings attached to the workhouse, insufficiently isolated and imperfectly ventilated, with 700 feet as a maximum, and 500 as a minimum, of cubic space to each patient. In these wards, typhus and small-pox were treated together, with the result that the fever convalescents often took small-pox, and the small-pox convalescents fever; in addition to which, cases of typhus occurred in the workhouse in such numbers as to lead to the inference that the extension of the disease was the result of overcrowding and deficient isolation. In connexion with this part of the subject, an important point has been illustrated in numerous well attested instances during this epidemic; namely, that the risk of the extension of typhus by contagion is certainly as great, and apparently much greater, in the convalescent stage, than at an earlier period of the attack; the obvious practical deduction from which is, the necessity for isolating typhus convalescents, and for deferring their discharge from hospital for a much longer period than would, under other circumstances, be thought necessary.

Besides the accommodation provided by the different parochial boards, there is a private hospital in Liverpool for the reception of contagious diseases, supported partly by voluntary contributions, and partly by a weekly payment from the patients. It contains twenty-four beds, affords sufficient cubic space, and is well ventilated.

The subject of most importance in Dr. Trench's

Report, next to typhus, is small-pox, which, after having been almost absent from the death-registry during the years 1860, 1861, and 1862, accounted in 1863 for 100 deaths, and in 1864 for 482; being 359 above the corrected average of the preceding ten years. Of these deaths from small-pox, 96 were registered as "vaccinated", and at the following ages; viz., one year and under, 15 deaths; between one and two years, 10; between two and five, 32; between five and ten, 12; between ten and twenty, 8; between twenty and thirty, 11; above thirty, 8.

Upon this statement, the medical officer of health observes: "On the subject of vaccination, its failure in 96 cases, supposing the statements to be approximately correct, shows, firstly, a want of care in its employment; and, secondly, the necessity of the process being repeated at stated intervals." Whether, upon so wide and important a question as the protective power of vaccination in reference to its duration, and the necessity of its repetition, it is safe to generalise from such limited statistics as 96 cases afford, is doubtful. Certainly, no satisfactory conclusion can be drawn from the two propositions, thus stated conjointly. If, for example, it be assumed that there is a want of care in the employment of primary vaccination, the necessity for repeating the operation, even if it do occur, proves nothing as to the duration of the protective influence of vaccination when properly and efficiently performed; and, therefore, cannot be urged as an argument in favour of re-vaccination, except as a precaution against the defects of the original operation.

No attempt is made to assign a cause for this epidemic of variola; and, indeed, the solution of this question presents much the same difficulties as exist in the case of fever. It appears that the disease prevailed most in the worst and poorest localities, though we must hesitate to pronounce destitution as the promoting cause of this zymotic. As to vaccination, it is probable that the practice is as efficient and universal in Liverpool as in any other of our large towns. No doubt, the system there is characterised by the same defects as those which obtain throughout this country. England gave birth to the immortal Jenner, but nevertheless is behind many other nations in providing for its people the fullest advantages of his invaluable discovery. It is, however, some consolation and encouragement to know that the medical department of the Privy Council are alive to the necessity of improvement in this important section of their functions.

—♦—
We are glad to find that another member of our profession is in the election-field; viz., Mr. Clement of Shrewsbury. Mr. Clement appeals to his professional brethren for assistance in electing one of

themselves. He says with truth, that the "army and navy, the law and the Church, are well represented in Parliament; but the medical profession has only one advocate in the present House of Commons. If some medical men had been in Parliament, they would not have seen such unsatisfactory and useless legislation on that very important subject, the public health." We sincerely hope that, in the excellent work of assisting a medical man into Parliament, our professional brethren will for once join heartily hand in hand, and give Mr. Clement their earnest support. Medical men of all shades of politics are assuredly, for such an end as this, bound to pledge to him their best support. Mr. Clement's local position and local influence are very great; and we can well believe that, with the energetic help of his professional brethren, he has a very good chance of being returned for Shrewsbury. We should really have a representative of the medical profession in the House, if Mr. Clement happily find his way into it.

VIRCHOW continues to hold a most remarkable—we might say unique—position as a leader in scientific medicine and a leader in politics. Our readers will have read the account of the threatened duel between him and the imperious and impertinent Bismark. Last year, Bismark told Virchow that he had better stick to his anatomy, which was more in his way than politics. This year, he sends Virchow a challenge, having, doubtless, by this time learnt that Virchow is something more than a mere anatomist. The question of duel or no duel is still *sub judice*. In the *Times* we read:

"The Lower House has held a meeting on the challenge given to Dr. Virchow by Herr von Bismark. Herr von Bismark, as a major in the Militia, is legally obliged to resent insult by calling out the insulter; while Herr Virchow, being no member of the army, would be liable to some months of imprisonment, at the least, were he to accept the challenge. Notwithstanding, few speakers thought it compatible with the creed of a Prussian gentleman to call upon Herr Virchow to refuse the duel on legal and moral grounds; the only reason of their objections being, that frankness in parliamentary debates would be rendered impossible were the decision as to insult to be referred by the President to the pistol. Herr Virchow offered to make reparation, provided Herr von Bismark would declare that he meant no offence in likening him to Hannibal Fischer—the man who fifteen years ago, at the end of the revolutionary period, was commissioned to put to the hammer the incipient fleet of the Germanic Parliament, and whose name has since been a byword in the mouth of the people. As a remarkable and rather amusing circumstance, it deserves to be mentioned that the police have had their misgivings as to the acceptance of the challenge by Herr Virchow. Ever since the Premier called out the Professor of Pathology, the Premier's colleague, who presides over the Ministry of Internal Affairs, has had the Professor dogged and watched by his myrmidons. When he attends hospitals, a *commissaire de police* will take up his station in front of the operating-hall; when he

leaves for the House of Deputies, a couple of alert detectives will track him thither, and wait patiently for his coming out."

A PETITION, signed by Messieurs les Ouvriers, has been presented to the Senate of France, asking that homœopathy may be introduced into French hospitals. To M. Dumas and a Committee has been committed by his brother senators the drawing up of a report on the subject. Before issuing a report, however, the Committee have applied to the Director of Public Assistance for his opinion; and M. Husson has, it is said, sent in a complete treatise on the subject. This incident has, as our readers may suppose, excited much the attention of the medical profession in France; and the report to the Senate of M. Dumas is looked forward to with anxiety. It is argued, that a petition of the kind alluded to from the very class who seek the benefits of the hospital cannot be lightly ignored; that those who go to the hospitals have a right to be treated by any system they please. The public pays for the hospitals, and therefore the public has a right to have all kinds of doctors there. And, if this be admitted, then will follow the soldier and sailor, etc., who will also demand the same right of choice in their medical treatment. And what can the Government oppose to this? All that can be done, it is argued, is, that the Government insist on the medical man being duly qualified to practise. How he practises, is a business which concerns himself.

A VERY interesting paper was lately read by Dr. Clouston, Medical Superintendent of the Cumberland and Westmoreland Asylum, before the Metropolitan Association of Medical Officers of Health. In this paper, he gives an account of an outbreak in the asylum of dysentery, which he asserts, and apparently on very logical grounds, was connected with the effluvia arising from the distribution of the sewage of the Asylum over land in the immediate neighbourhood. His paper deserves very serious consideration on account of the great care, precision, and circumstantiality, with which all the facts of the case are detailed. But, at the same time, the conclusions, however plainly they seem to flow from the premises, must not be accepted without grave consideration; and for this reason, that they seem so plainly contradicted by the facts attending the distribution of sewage elsewhere—as in the neighbourhood of Edinburgh, for example. Perhaps, it may be shown that the sewage in one case is in a different stage of decomposition from what it is in the other; that decomposing animal exuviae in sewers may at one period give off effluvia which are much more injurious to the human body than those given off at another—perhaps later—stage of its decomposition. In the present instance, Dr. Clouston ascribes the

effects of the sewage to the fact, that the sewage did not flow over a sandy and absorbing substratum of soil; but was retained on the surface by impervious beds of clay; and consequently was not fully subjected to the purifying influence of the soil.

THE friends of the Medical Provident Society will be glad to learn that it is now fairly in operation. A meeting of the Executive Subcommittee was held in London on the 9th instant—Dr. Richardson, and afterwards T. Heckstall Smith, Esq., in the Chair—when a number of contributing members were elected, after due examination of their certificates of health; and all the donors of ten guineas and upwards to the Auxiliary Fund were ordered to be placed on the list of honorary members. The contributors then elected were ordered to be enrolled from June 15th, and will be entitled to be aided by the sick-fund after the end of a year from that date. The Chairman and Secretary, with Mr. Clay, were directed to prepare the draft of a report of the Society before the next meeting of the Committee; and various other business was transacted. There is every reason to hope that the first report of the Directors, to be presented when the Association meets at Leamington, will contain much that is encouraging.

DR. VAN DER CORPUT, delegated by the Belgian Government to study the febrile epidemic at St. Petersburg, writes to the *St. Petersburg Journal* to express his indignation at the report spread by the *Wiener Medizin. Wochenschrift*, to the effect that the nature of the epidemic was concealed from the observation of foreign physicians. Dr. van der Corput says he has been received with open arms by all the Russian physicians and in all St. Petersburg hospitals. The epidemic, he says, is simply recurrent fever with typhus. Dr. van der Corput's letter is inserted in *L'Union Médicale*, at the request of Dr. Pelikan of St. Petersburg; and it appears also (suspiciously) in a St. Petersburg journal. For ourselves, we consider the report of secrecy confirmed by the significant fact already stated by us, that Dr. Whitley, who was sent to St. Petersburg by the British Government to study and report upon the nature of the epidemic, has up to this time given no notice whatever of it. If he saw and was satisfied, why is he silent?

ONE Morel and his wife were lately fined, at Niort, in France, 3260 francs for illegally practising medicine by means of animal magnetism—326 operations at 10 francs each! And, besides this, 1000 francs each for rogues and deceit, with a year's imprisonment. The two Morels appealed to the Court of Poitiers, who maintained the decision of the judges; but diminished the fine from 1000 to 300 francs, and the term of imprisonment to three months.

M. Demarquay lately presented to the Paris Surgical Society a man forty-eight years old, who had suffered great difficulty of speech, of mastication, deglutition, and respiration, in consequence of a tumour of the tongue. His general health had also suffered greatly. The soft palate could only be seen when the tongue was forcibly compressed. The patient could only eat with much difficulty; and M. Demarquay was on the point of tracheotomising him to relieve the respiration, when it occurred to him that he might usefully tie the two lingual arteries, which he did. On the day after the operation, the tumour began to diminish, and the atrophy was still going on. Although the patient was not completely cured, he could now talk, eat, and swallow; and his general health had become excellent. M. Broca hereupon remarked, that to the great Harvey belonged the priority of the idea of such an operation. Harvey tied the spermatic artery in a person who had a large tumour of the testicle, and thereby brought about its atrophy and absorption.

A national recompense has been demanded by the Belgian Academy of Medicine for Dr. Wilhems, on account of his discovery of the inoculation of epizootic peripneumonia.

MM. Manoury and Salmon, Surgeons of the Chartres Hospital, give an account, in the *Gaz. Méd. de Paris*, of an epidemic of colica pictonum which existed in the neighbourhood of Chartres. The cause of it was traced to lead which had been improperly used in mending the wheels of the mill, and had become mixed with the flour. Lead was found in the flour; and no further cases of colic were observed when it was no longer used for the purpose of stopping up holes in the wheel of the mill.

M. Chauveau of Lyons has made a very extensive and valuable series of experiments concerning the relation between small-pox and cow-pox. His conclusions are as follows.

Human small-pox can be inoculated on the ox and the horse with as much certainty as cow-pox. The effects resulting from the inoculation of the two virus differ completely. In the ox, small-pox virus produces only an eruption of very minute papillæ; but cow-pox virus produces a typical vaccinal eruption, with large and characteristic pustules. In the horse, small-pox virus also produces a papular eruption. Vaccine matter, as a rule, preserves the ox and the horse from variola; and variolous matter inoculated on these animals oppose the subsequent development of vaccinia. The variolous matter, when passed from animal to animal, never approaches in character to vaccinia. It remains in the last animal what it was in the first. When this variolous matter from the animal is inoculated in man it produces variola. Taken again from man and inoculated in the horse and the ox, it does not produce either cow-pox or horse-pox. Hence, therefore, notwithstanding the evident links of connexion between variola and vaccinia, in animals as in man, these two affections are yet perfectly independent, and cannot be transformed one into the other. And, consequently, in vaccinating after the method of Thielé or Ceely, we

practise the old inoculation, almost always rendered benign through the precaution which is taken to inoculate only the primitive accident, but certainly preserving all its dangers in respect of contagion.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFERSON, M.B. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S. Ed., Professor of Clinical Surgery in the University of Edinburgh.

Gentlemen intending to read papers, cases, or any other communications, are requested to give notice of the same to the General Secretary, at their earliest convenience.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

THE Committee of Council will meet at the Queen's Hotel, Birmingham, on THURSDAY, June 22nd, at Three o'clock precisely.

Business. To receive communications from the President.

To consider the Programme for the Annual Meeting.

To prepare the Report to be presented at the Annual Meeting.

To consider a Communication from Mr. Gamgee; and a correspondence between that gentleman and the Editor of the JOURNAL.

Any other business which may be brought forward.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, June 6th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
LANCASH. & CHESHIRE. [Annual.]	Royal Institution, Manchester.	Wednesday, June 21.
SOUTH-EASTERN. [Annual.]	Crystal Palace, Sydenham.	Thursday, June 22, 1 P.M.
SOUTH-WESTERN. [Annual.]	Westward-Ho Hotel, Northam Burrows.	Thursday, June 22nd, 2 P.M.
CAMBRIDGE AND HUNTINGDON. [Annual.]	Ely.	Tuesday, June 27th, 11 A.M.
MIDLAND. [Annual.]	Town Library, Town Hall, Leicester.	Wednesday, June 28th, 2 P.M.
NORTHERN. [Annual.]	Library, Newcastle- upon-Tyne Infirmary.	Wed., June 28, 10.30 A.M.
METROPOL. COUNTIES. [Annual.]	Crystal Palace, Sydenham.	Tuesday, July 4th, 3 P.M.
NORTH WALES. [Annual.]	Royal Hotel, Rhyl.	Tuesday, July 4, 12 noon.
WEST SOMERSET. [Annual.]	Clarke's Castle Hotel, Taunton.	Tuesday, July 4, 2.30 P.M.
EAST ANGLIAN. [Annual.]	Council Chamber, Town Hall, Ipswich.	Friday, July 14th, 2 P.M.

LANCASHIRE AND CHESHIRE BRANCH.

THE Annual Meeting of the Lancashire and Cheshire Branch will be held on Wednesday, June 21st, in the Royal Institution, Mosley Street, Manchester; THOS. TURNER, Esq., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Honorary Secretary, without delay.

WM. ROBERTS, M.D., *Hon. Secretary*.

89, Mosley Street, Manchester.

SOUTH-EASTERN BRANCH.

THE Annual Meeting of the South-Eastern Branch will be held at the Crystal Palace, on Thursday, June 22nd, at 1 P.M.; EDWARD WESTALL, M.D., President, in the Chair.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same to the Secretary, on or before Saturday, June 17th.

C. HOLMAN, M.D., *Secretary*.

Reigate, June 7th, 1865.

SOUTH WESTERN BRANCH.

THE Annual Meeting of the South-Western Branch will be held on Thursday, June 22nd, at the Westward-Ho Hotel, Northam Burrows, at 2 P.M.; T. L. PRIDHAM, Esq., in the Chair. The chair to be taken at half-past Two o'clock precisely.

The dinner will be held at the Westward-Ho Hotel, at half-past Four o'clock precisely.

C. H. ROPER, *Secretary*.

Exeter, June 1865.

CAMBRIDGE AND HUNTINGDON BRANCH.

THE Annual Meeting of the Cambridge and Huntingdon Branch will be held at Ely, on Tuesday, June 27th, at 11 A.M.; J. MURIEL, Esq., President, in the Chair.

Gentlemen intending to read papers or cases are requested to forward the titles of the same to the Honorary Secretary, without delay.

P. W. LATHAM, M.D., *Hon. Secretary*.

15, Sidney Street, Cambridge, June 1865.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

Gentlemen intending to read papers and cases, are requested to forward the titles of the same to the Secretary, without delay.

G. H. PHILIPSON, M.B., *Hon. Secretary*.

Newcastle-upon-Tyne, June 1865.

MIDLAND BRANCH.

THE Annual Meeting of the Midland Branch will be held on Wednesday, June 28th, at 2 P.M., in the Town Library, Town Hall, Leicester; JOHN BARCLAY, M.D., President.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, without delay, to the Honorary Secretary.

JOHN SLOANE, *Hon. Secretary*.

Welford Place, Leicester, June 1865.

WEST SOMERSET BRANCH.

THE Annual Meeting of the West Somerset Branch will be held at Clarke's Castle Hotel, Taunton, on Tuesday, July 4th, at 2.30 P.M.; HUGH NORRIS, Esq., President.

Gentlemen are requested to give notice to the Secretary of cases or papers they may wish to communicate.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, June 1865.

EAST ANGLIAN BRANCH.

THE Annual Meeting of the East Anglian Branch will be held in the Council Chamber, Town Hall, Ipswich, on Friday, July 14th, at 2 P.M.; A. H. BARTLET, M.D., President.

Dinner at 5 P.M.

Members are requested to forward to Dr. Chevallier the titles of any papers or cases they may wish to communicate, on or before June 30th.

B. CHEVALLIER, M.D., *Hon. Secretary.*

Ipswich, June 14th, 1865.

SOUTH MIDLAND BRANCH: ANNUAL MEETING.

THE ninth annual meeting of this Branch was held at the Infirmary, Northampton, on Wednesday, June 7th, at 2 P.M.; GEORGE ASHDOWN, Esq., President, in the Chair. There were also present—Drs. J. M. Bryan, D. J. T. Francis, C. C. Hicks, E. Lawford, A. D. Mackay, W. Paley, and O. B. Shore; F. Buszard, M.B.; Jabez Carter, Esq.; R. Ceely, Esq.; R. Death, Esq.; C. J. Evans, Esq.; G. P. Goldsmith, Esq.; H. Hailey, Esq.; J. H. Hemming, Esq.; T. N. Heygate, Esq.; C. Hooper, Esq.; J. P. Knott, Esq.; J. G. Leete, Esq.; F. H. Marshall, Esq.; J. Mash, Esq.; W. Moxon, Esq.; E. Olive, Esq.; F. Southam, Esq.; T. J. Starling, Esq.; H. Terry, Esq.; H. Terry, jun., Esq.; W. H. Walker, Esq.; and R. W. Watkins, Esq.; and as visitors—Dr. Ramsey; J. M. Bryan, jun., Esq.; J. Green, Esq.; J. C. Green, Esq.; W. J. Kite and J. Manley, Esqrs. (West Bromwich); and T. Watkin Williams, Esq. (Birmingham); etc.

In the absence of H. VEASEY, Esq., the retiring President, the President-elect, G. ASHDOWN, Esq., took the Chair, and made a short speech, in which he alluded to the circumstance that a prize of Ten Guineas had been offered by Dr. Lawford of Leighton Buzzard to the members of the Branch, for the best essay "On the Constitutional Changes in the Human Frame resulting from Inebriety."

The minutes of the last meeting were read and confirmed. The Honorary Secretary, Dr. BRYAN, in reading them, remarked that the Branch was in a most flourishing state, there being eighty-five members (with four new ones to be proposed). The funds in hand amounted to £7:5.

Officers and Council. The following gentlemen were unanimously elected as the officers and Council for the year 1865-6. *President:* G. Ashdown, Esq., Northampton. *President-elect:* E. Lawford, M.D., Leighton Buzzard. *Committee of Management:* T. H. Barker, M.D., Bedford; Jabez Carter, Esq., Bedford; R. Death, Esq., Buckingham; D. J. T. Francis, M.D., Northampton; J. Francis, Esq., Market Harborough; H. Hailey, Esq., Newport Pagnell; W. Moxon, Esq., Northampton; and H. Terry, jun., Esq., Northampton. *Representatives in the General Council:* E. Daniell, Esq., Stony Stratford; W. Paley, M.D., Peterborough; H. Veasey, Esq., Woburn; R. W. Watkins, Esq., Towcester. *Treasurer:* J. M. Bryan, M.D.,

Northampton. *Honorary Secretaries:* J. M. Bryan, M.D.; and G. P. Goldsmith, Esq., Bedford.

Medical Provident Society. E. Daniell, Esq., and J. M. Bryan, M.D., were elected to represent the Branch on the Board of Directors of the Medical Provident Society.

Autumnal Meeting. It was resolved that the next autumnal meeting be held at Market Harborough, in September.

New Members. The following gentlemen were admitted as members of the British Medical Association and of the South Midland Branch: E. Bishop, Esq., Culworth; C. J. Evans, Esq., Northampton; J. Q. Costin, Esq., Market Harborough. O. B. Shore, M.D., Stamford Baron, a member of the Association, was admitted a member of the Branch.

THE BRITISH MEDICAL JOURNAL. A discussion on the JOURNAL, adjourned from the last meeting of the Branch, was resumed.

Mr. DEATH (Buckingham) proposed—

"That it is the opinion of this Branch that the Association do not publish a separate JOURNAL."

This motion, apparently, was not seconded.

Several members having made remarks,

Mr. R. W. WATKINS (Towcester) proposed the following resolution:

"That this meeting acknowledges the earnest endeavours of Dr. Markham to improve the character of the JOURNAL; and hopes that the members of the Association, more especially those who are connected with the public medical institutions, will support his efforts by contributing the results of their practice to the JOURNAL."

Mr. WATKINS said that the JOURNAL was much better now than at any previous period. Dr. Markham had conducted it with great ability; and, under his management, the Association had increased by several hundred members. He had some time since great reason for objecting to the *Lancet*, as it was constantly filled with anonymous attacks on individuals, and its articles manifested too much personal feeling. He had discontinued it for some years. With respect to the JOURNAL, if there were one point deficient, it was in communications from the physicians and surgeons of provincial hospitals. He hoped they would communicate more, and thus support the editor and improve the character of the JOURNAL. It only wanted their assistance to make it a first-class journal.

The motion was seconded by Mr. HAILEY (Newport Pagnell), and carried unanimously. In the discussion on it,

Mr. TERRY, sen. (Northampton), said he could not feel satisfied with giving a silent vote on the question, but must express the high opinion he entertained of the JOURNAL and of the able manner in which it was conducted. He had always entertained the idea, that it was mainly by the JOURNAL that the Association was kept together. He believed that not one-twelfth of the members of the Association attended the meetings; but that the members generally felt interested in the Society, and in reading about the doings of their medical brethren. There were other journals, but not, strictly speaking, journals of the profession. THE BRITISH MEDICAL JOURNAL was for the profession and the Association; and, if it were given up, the Association would at once dwindle. He thought that the plan proposed by Mr. Carter was visionary. The Association had already done much good; and the way to do more good was to keep it together. He concluded by expressing his strong feeling in favour of the JOURNAL.

Mr. MASH (Northampton) agreed with every remark made by Mr. Terry. The editor had fought manfully for the profession, and the members of the

Association ought to stick to the JOURNAL. He hoped that it might be gradually still more improved; but his motto was, "Keep to the good old JOURNAL."

MR. GOLDSMITH (Bedford) said that at the last meeting he had been commissioned by Dr. Barker to move the approval of Dr. Markham's management. The discussion, however, had been adjourned.

MR. WATKIN WILLIAMS, the General Secretary of the Association, who was present as a visitor, made a very able and energetic speech, which was received by the meeting with much approbation and applause.

Papers. The following papers were then read.

1. Case of Elephantiasis of the Lower Extremities; with an Illustration. By Hammett Hailey, Esq., Newport Pagnell.

2. Case of Monstrosity in the Fœtus. By J. Carter, Esq., Bedford.

3. Case of Tying the Subclavian Artery for Aneurism. By Robert Ceely, Esq., Aylesbury. The subject was brought for inspection. It was a most interesting case; the cure being complete.

4. Case of Puerperal Convulsions passing into Mania. By A. D. Mackay, M.B., Stony Stratford.

5. Case in Midwifery: Hæmorrhage after the Ninth Day (fatal). By G. P. Goldsmith, Esq., Bedford.

7. A few Remarks in the Treatment of Delirium Tremens. By D. J. T. Francis, M.D., Northampton. Several instances were related where large doses of opium had been given without good effect; and although some patients had recovered under this plan, yet he (Dr. Francis) had tried simple treatment, giving merely a *placebo*, such as small doses of hyoscyamus and bismuth, with diminished quantity of stimulus, and the disease had subsided sooner than in previous attacks. He instanced a case occurring the fifth time in the same patient, who was exceedingly violent. From the first, he gave no opium, but something simple; and the patient recovered more quickly than at former times. Some months ago, he saw a severe case with Dr. Bryan, which was treated by small doses of tincture of digitalis (ten to twenty minims every four hours) and a moderate supply of stimulus. The patient recovered quickly. He thought that the disease had a natural tendency to expand itself, if not kept up by a large supply of stimulus. There were facts known of bad cases recovering without the use of any opium at all.

MR. MASH related an extraordinary case to which he was called. It was stated to be quite hopeless. He gave thirty minims of tincture of opium every hour or two, with a good result.

MR. HAILEY had never found opium to fail.

MR. HEMMING (Kimbolton) generally gave opium.

MR. CEELY had seen opium given in large doses, and the complaint yielded under this treatment. He thought there were two kinds of cases; one where the patient had just drank to excess, and was in a very excited state, where he would give tartar emetic and effervescent draughts; and another where drinking had been left off for a little time, leaving prostration to a certain extent. Here he would give small doses of opium, and porter.

Votes of Thanks. A vote of thanks was passed to the gentlemen who had read papers, with a request that they would allow them to be published in the JOURNAL.

A vote of thanks was also given to the President for his able conduct in the chair.

Dinner. The meeting was then adjourned to the George Hotel, where the members and visitors, to the number of twenty-four, sat down to a good dinner there provided.

The members and visitors, to the number of forty

or more, had been previously sumptuously entertained at a luncheon provided by George Ashdown, Esq., President, at 1 P.M., at the same place.

Reports of Societies.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 5TH, 1865.

ROBERT BARNES, M.D., President, in the Chair.

Specimens. Dr. J. BRAXTON HICKS exhibited an improvement on the mode of fastening the rope in his *Ecraseur*, which will allow any length of rope to be used, thus doing away with the addition of the endless drum of Weiss. Instead of using one hook or button on which to fasten the moving end, two hooks are now employed back to back, whereby two figure-of-eight hitches can be made, sufficient to keep the rope from slipping. Should, during an operation, the hooks come down to the end of the screw without having brought all the noose through the eye or severed the growth, the hitch can be undone, the hooks run up to the top of the screw, the ropes re-fastened, and brought down again as at the commencement. The hooks should be made as neatly as possible, but deep enough to hold two turns of rope.

Dr. MARION SIMS exhibited a new form of Curette for the removal of uterine fungoid granulations.

Dr. GREENHALGH showed a new form of Uterine Tent made from the stem of the *laminaria spiralis*; the peculiarity being that it is a hollow tube instead of the solid stick heretofore used. He also showed a new Pelvimeter, in which the index-finger is made available for the purpose of measurement, the size of the pelvic brim being determined by a little contrivance fixed upon the examining hand.

The PRESIDENT exhibited an instrument which he had used for some time past for the purpose of Dividing the Cervix Uteri in certain cases of Dysmenorrhœa, Metrorrhagia, and Sterility. It resembled the scissors used for the same purpose by Dr. Marion Sims.

MR. R. KING PEIRCE showed a Fœtus, born at full time, and exhibiting at birth two lacerations: one extending through the integuments transversely across the abdomen, about the level of the scrobiculus cordis; a second one across the throat, exposing all the vessels and muscles of the neck. The two lacerations had all the appearance of incised wounds; but the evidence was clear that they had not been produced by any act of violence other than that of rapid delivery.

Dr. TANNER exhibited a Fœtus, the subject of Hernia Cerebri and Hernia Umbilicalis. A portion of the membranes were also adherent to the cranium. He also exhibited a photograph of an Anencephalous Fœtus.

On a Case of Œdema after a Fall on the Gravid Uterus; Premature Labour; Recovery. By A. RASCH, M.D. The woman, at the end of the seventh month of her second pregnancy, fell down a steep flight of steps on her abdomen, and soon afterwards found herself swollen all over the lower half of the body. The Œdema increased to such an extent, that her medical attendant considered her case hopeless. Dr. Rasch saw her eight days after the accident. She had enormous Œdema of the belly from the navel downwards; the labia were distended into huge water bladders; both legs swollen; right hypogastric region painful on pressure; a good deal of albumen in the urine, but no casts; pulse quiet; tongue clean.

She never had the slightest œdema before the accident. After a few days, Dr. Rasch induced premature labour, and the albumen and œdema then perfectly disappeared. Dr. Rasch considered the case interesting in point of diagnosis; and held that the œdema was produced by the pressure of the uterus on the vena cava inferior, which would also account for the albuminuria. The author then specially directed the attention of the fellows to Breslan's mode of inducing premature labour, by simply introducing and keeping in the uterus an elastic catheter.

Dr. TYLER SMITH remarked that this operation was much practised by Professor Simpson in Edinburgh.

In reply to Dr. Graily Hewitt, Dr. RASCH remarked that a distended bladder could not have been the cause of the œdema, as there were no symptoms of retention. He also differed from Dr. Hewitt as to the possibility of coagula in the vena cava having caused the œdema, as they could not have disappeared so rapidly without symptoms of embolism. He (Dr. Rasch) could not explain the case otherwise than by pressure of the uterus on the vena cava, which was very favourably situated for that condition where it passes over the right side of the sacral promontory.

Remarks on the Influence of Mental Impressions as a Cause of Bodily Deformity. By A. MEADOWS, M.D. Dr. MEADOWS read the particulars of a Case of Monstrosity. Having first expressed his conviction in favour of the proposition, that the mind can and does act in this way, he reviewed and combated the various objections urged against it; the principal one being the absence of any direct connection between the nervous system of the mother and that of the fœtus through the umbilical cord. He, however, endeavoured to prove—or rather suggested the possibility, as it was not a matter admitting of any distinct proof—that mind, or the mental force, was not and could not be thus bound down, as it were, by the anatomical limits of the nervous structures; that it must have a power of action, if it has any action at all, throughout the entire organism, and in every part of it, whether it possessed nerves or not: in other words, that its sphere of action was only limited by the configuration of the body. Hence it was inferred that in those tissues where the existence of nervous elements could not be demonstrated, the mental or nerve force might, as it were, pass across the intervening matter between any two parts where nerves did exist, just as electricity traversed space between any two conductors. The author then applied this reasoning to the case of the fœtus *in utero*, and offered an explanation of the mode by which mind thus acts upon matter by supposing a kind of correlation between mental and nerve force analogous to the correlation of other physico-vital forces; the nerve force being here the active agent in those nutritive processes upon the changes of which deformities depend.

Dr. RASCH said he had listened with great pleasure to Dr. Meadows's paper, which boldly took up what was generally left to women, but which certainly deserved scientific investigation. The belief in the influence of mental emotion on the formation of the fœtus was as old as it was general amongst women. The great difficulty was to establish facts, as the mothers always recollected something from their pregnancy *after* they found something abnormal in their children. Dr. Rasch had seen two cases which had somewhat struck him, and of which he had taken notes. Two boys, from different parts of Germany, were brought to him with scarcely any foreskin, looking exactly like circumcised little Jews, but without any cicatrices. Both women narrated, with great

emotion, how they had seen during their pregnancies little Jews so cruelly treated that they could not forget it! They both had been present at the well-known Jewish rite. He ought to mention, however, that he had observed the same state in other little boys where no such story was volunteered, and where the mothers *did not know that this state was abnormal*. He considered this influence on the fœtus an open question, which he had made up his mind to help in solving whenever there was an opportunity of doing so.

The PRESIDENT observed that the instances most strongly bearing upon the question were those in which pregnant women stated explicitly the emotions supposed to influence the form of the fœtus *in utero* which they had undergone. One such case had been placed in his hands by Dr. Hassall, of Richmond. Certainly, the facts of this were very remarkable, inasmuch as the event singularly confirmed the statement of the woman made before her child was born. Dr. Barnes remarked that malformations were common amongst birds as well as quadrupeds; and that in birds it must be concluded that any mental impression must be imparted in the earliest stage of development—i. e., before the ovum was invested with the shell. He cited an anecdote from Captain Speke, which showed that in some tribes in Africa the belief prevailed that emotion in the *father* might produce monstrous births. The traveller had ordered his native huntsman to expose the embryo in a pregnant doe. He shrank from the task, fearing lest the kid striking his mind should metamorphose his wife's future progeny to the likeness of a fawn.

JAMES ALDERSON, M.D., F.R.S., President, in the Chair.

ON AMPUTATION OF THE LEG BY A LONG RECTANGULAR FLAP FROM THE CALF.

By HENRY LEE, ESQ., F.R.C.S.

THE author called attention to Mr. Hey's mode of operating by means of a long flap from the back of the leg, and to Mr. Teale's plan by a long rectangular flap from the front. The advantages of both these plans might be combined by making a rectangular flap from the back instead of from the front of the leg; a thick soft cushion might thus be provided for the ends of the bones, and no large nerve need be left in the flap. The operation described was performed according to Mr. Teale's plan as far as the external incisions were concerned, but the long flap was made from the back instead of from the front of the limb. Two parallel incisions were made along the sides of the leg; these were met by a third transverse incision behind, which joined the lower extremities of the first two. These incisions, which formed the three sides of a square, extended through the skin and cellular tissue only. A fourth incision was made transversely through the skin in front of the leg, so as to form a flap in this situation, one-fourth only of the length of the posterior flap. When the skin had somewhat retracted by its natural elasticity, an incision was made through the parts situated in front of the bones, which were reflected upward to a level with the upper extremities of the first longitudinal incisions. The deeper structures at the back of the leg were then freely divided in the situation of the lower transverse incision. The conjoined gastrocnemius and solcus muscles were separated from the subjacent parts and reflected as high as the anterior

flap. This part of the operation was performed with the greatest facility on account of the loose attachments of these muscles, especially at the lower parts of the leg. The deeper layer of muscles, together with the large vessels and nerves, were divided as high as the incisions would permit, and the bones sawn through in the usual way. The flaps were then adjusted in the manner recommended by Mr. Teale. The long flap thus formed was much thicker than when taken from the front of the leg. It was consequently less liable to slough. It afforded a much more efficient protection to the ends of the bones, and a thicker and softer pad upon which to rest a part of the weight of the body when an artificial limb was applied.

Three cases were detailed in which this mode of operating had been adopted, and drawings were given of the stumps after they had healed.

Two other cases were mentioned. In one of these, which was performed after great loss of blood from ulceration of the anterior tibial artery, in a case of very severe compound fracture, the patient died. In the other case, the patient made a rapid and good recovery. These were, the author believed, all the instances in which this particular operation had been performed.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, APRIL 7TH, 1865.

GEORGE FINCHAM, M.D., President, in the Chair.

Fracture of the Skull. Dr. MARTYN gave the particulars of a case of fracture of the skull from *contrecoup*. This occurred to a gentleman who was found dying in his bed in the morning, having left his home the previous evening in good health. When seen by the author, he was already dead. A *post mortem* examination showed a scalp-wound over the right parietal protuberance; and, upon dissecting off the scalp and sawing through the skull, a large clot of blood was found beneath the dura mater, on the left side of the base, chiefly occupying the middle fossa. This had proceeded from the middle meningeal artery, which had been ruptured by a fracture which traversed it. The fracture extended downwards and forwards and upwards and backwards to the extent of three or four inches, just in a direction corresponding to the line of the wound of the scalp. It did not reach the foramen magnum. There was no trace of bruise or wound on this side of the head. The author justified his idea of this fracture occurring by *contrecoup*, from the absence of any evidence of a blow or fall injuring the left side of the head directly. The injury was supposed to have been caused by a blow from some heavy body, as a poker; and, from the patient's history, there was reason to believe he had been subjected to some violence.

Strangulated Femoral Hernia. Miss F., aged 42, had suffered from this rupture for about fifteen years. On the morning of February 22nd, she first had "twisting pain" of the belly; and, although she took purgatives and used injections, could not get a passage through the bowels. She was seen on the evening of that day by Dr. MARTYN, who found her vomiting, in much pain, and in great distress. He at once discovered the nature of the case. The attempt made to reduce the tumour by the taxis failed; therefore her hips were raised, and ice applied, and she was advised to be put under chloroform for the purpose of again attempting its reduction; failing which, the usual operation for her relief was recommended. The

patient strenuously opposing these proceedings, opium in grain doses every hour was ordered. The next day, the patient was found to be much relieved by the opium, and would submit to no further treatment. On the following day (Monday), at 11 P.M., the author's attendance was again requested, the patient's symptoms being greatly aggravated. The abdomen was greatly distended; the vomiting was incessant; and her appearance indicated great prostration. She would now submit to anything for relief. As no assistance could be obtained at that time, and the case being urgent, with the help of his own assistant, he proceeded to operate, first placing the patient under chloroform. A knuckle of intestine, of the size of a small walnut, occupied the sac, which was strictured at the crural arch. This was divided, and speedy relief obtained. The bowels acted spontaneously three or four times in the night; and she afterwards went on well, without a bad symptom. The author considered the above case of some practical importance, from the length of time that had elapsed, with all the active symptoms of strangulated hernia going on for six whole days, and the operation eventually proving successful. Dr. Martyn thought that the long duration of the rupture (fifteen years) favoured the result from the bowels having become more tolerant of the injury.

Transfusion of Blood. Dr. GRAYLY HEWITT exhibited an instrument for the transfusion of blood, which, from its simplicity, would greatly assist in effecting the perfect performance of the operation. Its exhibition was accompanied by some remarks upon the nature of the cases requiring the operation, and of the mode of performing it.

Correspondence.

BEEF-TEA.

LETTER FROM WILLIAM KING, M.D.

SIR,—Your remarks on the waste of muscular food, in the number for June 3, have induced me to send you the following method of preparing food for delicate invalids, and those who are recovering from serious illness. It has a French origin, and was called *bœuf-pourré*.

Take one pound of beef, picked clean, pound it in a marble mortar into a pulp, add to it half a French roll sopped in gravy, and pound them well together; add to them the white and yolk of one egg, and pound all well together, adding a little spice to flavour it; puddle them through a hair sieve, scraping it off on the underside with a spoon as it oozes through; the whole will pass through if properly done; tie it up in a cloth, and boil for an hour. This preparation I used for many years when I was in practice, with great benefit.

The waste which you describe in muscular fibre in making beef-tea, is so enormous as to be well nigh incredible. While I was physician to the Sussex County Hospital, we had our broth-days two or three days in the week. Many of the patients disliked the broth, though well made with meat in it. We were allowed to order things, under the general name of fancy diet, which some of the economic governors thought extravagant; the hospital itself was always liberal.

I always thought the broth a poor innutritious diet, and I think the stomach has an aversion to fluids as a diet, and can digest solids, properly prepared, better. I am sorry to say that I did not inquire what became of the muscular fibre left from beef-tea; but I think

the waste of our broth, with meat in it, was not so great as you describe it. A physician ought to be a cook as well as a pharmacologist; for a good and pleasant diet is the basis of health, in a hospital as out of it.

Surely, that muscular fibre, which you mention as wasted, might, if pounded with bread, and a proper quantity of spice to flavour it, be made into a nutritious diet, either in the hospital or out of it, to thousands who seldom taste meat in any shape. We know that it is the muscular fibre, which we eat, which alone nourishes the muscle. Certainly, the physician is not a cook, and the cook is a jealous person, and does not like to be dictated to, even by the physician. But this waste is either incredible, or a great crime. I am, etc.

WILLIAM KING, M.D. Cantab.

23, Montpellier Road, Brighton, 6th June, 1865.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. The following members of the College, having undergone the necessary examinations at a meeting of the Board on June 7th, received the Licence in Midwifery.

Acey, Thomas, Hull; diploma of membership dated July 16, 1858
Ayres, Philip Burnard Chenery, Bedford; November 15, 1864
Bugden, Richard, Tachbrook Street, Pimlico; May 11, 1865
Cass, William Cunningham, Cowes, Isle of Wight; May 23, 1865
Collier, Thomas, Bridgend, Glamorganshire; July 26, 1864
Evans, John Tasker, Hertford; April 12, 1864
Fry, Augustin Barber, Kibworth, Leicestershire; May 24, 1864
Gourley, Samuel, West Hartlepool (not a member)
Knipe, William Melville, Rotherhithe; May 24, 1864
Rains, Samuel, Manchester; January 21, 1865
Roche, John, Fermoy, Ireland; April 8, 1866
Strange, William Heath, Streteley, near Reading; May 24, 1864

Admitted as Fellows of the College.

Beaumont, Thomas Mills, Knaresborough; diploma of membership dated April 11, 1864
Berney, Edward, Croydon; May 3, 1841
Donald, Joseph Rickerby, Holloway; November 1, 1839
Fereday, Samuel Day, Dudley; November 11, 1836

UNIVERSITY OF CAMBRIDGE. Degree of M.D. conferred at a Congregation held on June 8.

Phillipson, George Hare, Caius College

Degree of Master in Surgery.

Balla, Walter, St. Peter's College

First M.B. Examination. Easter Term, 1865. Examined and approved.

Bell, W. A., B.A., Trinity Hall
Dalby, W. B., B.A., Sidney College
Lestourgeon, Charles, M.A.

Second M.B. Examination. Easter Term, 1865. Examined and approved.

Lee, R. J., B.A., Caius College

APOTHECARIES' HALL. On June 8th, 1865, the following Licentiates were admitted:—

Andrews, Richard James, Trinity Square, Tower Hill
Birch, George, Enfield Road, De Beauvoir Square
Fuller, James Mortimer, Park Road, St. John's Wood
Gourley, Samuel, West Hartlepool, Durham

At the same Court, the following passed the first examination:—

Hopgood, Thomas Frederick, University College Hospital
Spratt, William, Guy's Hospital

APPOINTMENTS.

ARMY.

ARDEN, Surgeon-Major W., 14th Hussars, to be Staff-Surgeon-Major, *vice* O. B. Miller.
BOILEAU, Staff-Assistant-Surgeon J. P. H., M.D., to be Assistant-Surgeon 29th Foot, *vice* W. L. Farmer.
CARPENTER, Staff-Assistant-Surgeon W., M.D., to be Assistant-Surgeon 26th Foot.
CORBAN, Staff-Assistant-Surgeon L., M.D., to be Assistant-Surgeon 43rd Foot.

DAVIS, Assistant-Surgeon J. N., 44th Foot, to be Staff-Assistant-Surgeon, *vice* W. Carpenter, M.D.
FARMER, Assistant-Surgeon W. L., 29th Foot, to be Assistant-Surgeon 16th Lancers.
GREENHILL, Assistant-Surgeon J. R., 72nd Foot, to be Staff-Assistant-Surgeon, *vice* L. Corban, M.D.
JAMESON, Staff-Assistant-Surgeon W. H., to be Assistant-Surgeon 41st Foot.
KEIR, Staff-Assistant-Surgeon W., M.D., to be Assistant-Surgeon 16th Foot, *vice* R. W. Saunders, M.D.
MAUNSELL, Assistant-Surgeon T., 48th Foot, to be Staff-Assistant-Surgeon, *vice* E. O'Sullivan.
MILLER, Staff-Surgeon O. B., to be Surgeon 14th Hussars, *vice* Surgeon-Major W. Arden.
O'SULLIVAN, Staff-Assistant-Surgeon E., to be Assistant-Surgeon 96th Foot.
TROUP, Assistant-Surgeon R. W., 54th Foot, to be Staff-Assistant-Surgeon, *vice* W. H. Jameson.

ROYAL NAVY.

ANDERSON, James R., Esq., Surgeon, to the *Fisgard*, for Greenwich Hospital.
BROWNE, Francis H., Esq., Assistant-Surgeon, to the *Achilles*.
CLOSE, Henry A., Esq., Assistant-Surgeon, to the *Arethusa*.
COLLINS, A., Esq., Surgeon (additional), to the *Edgar*.
GRAHAM, William, Esq., Assistant-Surgeon, to the *Octavia*.
KYNSEY, Josiah F., Esq., Assistant-Surgeon, to the *Orontes*.
MARTIN, James J., Esq., Surgeon, to the *Arethusa*.
NASON, C. H., Esq., Assistant-Surgeon, to the *Prince Consort*.
RICHARDSON, William, Esq., Surgeon, to the *Octavia*.
SECCOMBE, Thomas, Esq., Surgeon, to the *Constance*.
SEDGWICK, Henry N. M., Esq., Assistant-Surgeon, to the *Octavia*.
SWEETMAN, Stephen, Esq., Assistant-Surgeon, to the *Constance*.
TREVAN, Matthew, Esq., Assistant-Surgeon, to the *Constance*.
WADE, Seaton, Esq., Surgeon, to the *Asia*.
WRIGHT, George V., Esq., Assistant-Surgeon, to the *Arethusa*.

MILITIA.

SMITH, T. S., Esq., to be Assistant-Surgeon 4th Lancashire Militia.

VOLUNTEERS, (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

ANDREW, Edwyn, Esq., to be Assistant-Surgeon 1st Administrative Battalion Shropshire R.V.
ANNINGSON, J., Esq., to be Assistant-Surgeon 1st Yorkshire R.V.
BASS, H., M.D., to be Surgeon 1st Administrative Battalion Tower Hatolets R.V.
HOWSIN, F. A., M.D., to be Honorary Assistant-Surgeon 28th Yorkshire R.V.
PADLEY, G., Esq., to be Assistant-Surgeon 1st Glamorganshire A.V.
PRIOR, C. E., Esq., to be Honorary Surgeon 1st Huntingdonshire Light Horse Volunteer Cavalry.

DEATHS.

BEATSON. On May 7th, at Calcutta, Mary Augusta, wife of *W. B. Beatson, M.D.

*FOREMAN, Robert C., M.D., at Brighton, aged 42, on June 11.

KING, Gilbert L., Esq., Surgeon R.N., at Plymouth, aged 32, on June 9.

*MACY, Henry J., Esq., of Westown, near Bristol, at Gosport, on June 9.

SOUTHEY, Henry H., M.D., F.R.S., D.C.L., at 1, Harley Street, aged 81, on June 13.

PROFESSOR OPFOLZER has received an autograph letter of thanks from the Emperor of Russia, and the second class of the order of St. Anna.

ASSOCIATION OF MEDICAL OFFICERS OF ASYLUMS AND HOSPITALS FOR THE INSANE. Dr. Wood is the President-elect of this Association. The annual meeting will be held at the College of Physicians on July 6th.

TESTIMONIAL TO MR. EDGELOW. The students of St. George's Hospital have presented their late Demonstrator of Anatomy, Mr. Edgelow, with a testimonial—a lathe and a case of dental instruments.

ARMY SANITATION. Dr. Haurowitz, the private physician of the Grand Duke Constantine, has been sent by the Russian Government to North America, to investigate and report upon the sanitary arrangements of the army made in connexion with the war.

SOCIETY OF SWISS NATURALISTS. The annual meeting of this Society will this year be held at Geneva, August 21st to 23rd, under the presidency of Professor de la Rive. This Society has been established fifty years.

THE DEATH-RATE IN VIENNA was 40 per 1000 during the week ending the 27th ult., when the temperature was 4.1° Fahrenheit higher than in the same week in London, where the rate was 22 per 1000.

ROYAL COLLEGE OF SURGEONS. The President and Council of the Royal College of Surgeons have invited the Fellows and Members of the College to a *soirée*, to be held at the College on the 28th inst.

DR. EDWIN LEE has been nominated a corresponding member of the Royal Academy of Medicine of Belgium, and of the Society of Medical and Natural Sciences of Brussels.

SURGEON TO THE QUEEN. The office of surgeon in ordinary to the Queen in Scotland has become vacant by the death of Dr. David MacLagan. The post is not a very onerous one, the health of her Majesty and her family happily not requiring much medical aid during her Scottish residences, but it is esteemed one of great honour.

POOR-LAW MEDICAL RELIEF. In a debate in the House of Commons on Monday last, on the Poor-law Board Continuance Bill, Mr. Neate said that the medical profession ought to have an opportunity to bring the grievances which, rightly or wrongly, they held themselves to suffer before the house, and which, if the present opportunity was refused them, could not be afforded them. Mr. Villiers, in reply, said the Committee had come to the conclusion that there was no sufficient ground for changing the present system of medical relief.

THE ORDER OF THE BATH. The Queen has been graciously pleased to give orders for the appointment of Alexander Bryson, M.D., Director-General of the Medical Department of the Navy, to be an ordinary member of the Civil Division of the third class or companions of the Order of the Bath. On the 8th inst., Sir J. B. Gibson, Director-General of the Army Medical Department, and Inspector-General Sir William Linton, were invested with the Riband and Badge and Star of the Military Division of the second class of the Order.

PARLIAMENTARY VOTES. The following sums have been voted by the House of Commons: £1,600 for the Westmoreland Lock Hospital, Dublin; £700 for the Rotunda Lying-in Hospital, Dublin; £200 for the Combe Lying-in Hospital, Dublin; £5,600 to complete the vote for the House of Industry Hospital, Dublin; £1,500 to complete the sum for Cork Street Fever Hospital, Dublin; £600 for the Meath Hospital; £100 for St. Mark's Ophthalmic Hospital, Dublin; £300 to complete the sum for Dr. Steevens's Hospital, Dublin; £245 for the board of superintendence of the hospitals in Dublin.

HYDROPHOBIA. An inquest was held last week at Westminster Hospital, on a lad, aged 17, who died of hydrophobia, having been bitten by a dog nine weeks since. He patted the dog, when it turned round and bit him on the hand, and then ran off. Shortly afterwards a violent pain in the hand ensued, and a woman washed the wound with warm water. He then went home to bed, and a doctor was called in. He continued very ill until the 2nd instant, when he was brought to the hospital. Mr. C. Hawkins, senior house-surgeon, saw two cicatrices on the left hand about an inch apart. The deceased was suffering from symptoms of hydrophobia. He had cramps, a flow of saliva from the mouth, and an intense desire to drink. When water was offered him, he clutched the vessel, but was unable to drink. His face became black and turbid, and his eyeballs protruded. Opium and soothing medicine were administered. The cause of death unquestionably was hydrophobia.

THE RATE OF MORTALITY last week was 22 per 1000 in London, 28 in Edinburgh, and 25 in Dublin; 34 in Liverpool, 25 in Manchester, 26 in Salford, 15 in Birmingham, 24 in Leeds, 21 in Bristol, 23 in Hull, and 31 in Glasgow.

WESTMINSTER HOSPITAL. At a special general meeting of the governors of the hospital, held on the 6th instant, the Marquis of Westminster, K.G., was unanimously elected president, in the room of the late Duke of Northumberland, K.G.

DEATH OF DR. SOUTHEY. This eminent physician, brother of the poet, expired on Monday, at his residence in Harley Street, in the 82nd year of his age. He attained the title of M.D. at Edinburgh in 1806, and was chosen a Fellow of the Royal College of Physicians in 1812; he was also a Fellow of the Royal Society, and a D.C.L. of Oxford. His professional studies and reputation, however, were chiefly in connection with lunacy, in which he was one of the highest medical authorities, being for many years Examiner of Lunatics to the Court of Chancery. The deceased gentleman was physician in ordinary to George IV, and physician to the London Hospital; holding, also, the appointment for many years of Graham Professor of Medicine, which is now vacant by his death. Dr. Southey was the author of various medical works, of which one of the most important was on *Pulmonary Consumption*.

GREENWICH HOSPITAL FUND. In the discussion in the House of Commons on this subject, on the 8th instant, Mr. Hennessy said, in reference to a clause providing that pensions should be granted to "officers," that it appeared that the term "officers" did not include medical officers or chaplains. Chaplains were dealt with by a subsequent clause, and therefore medical officers were the only class of officers who were excluded from the benefits of this bill. This was the more unjust because the commissioners who inquired into the state of Greenwich Hospital reported that the only part of the establishment which required no reform was that which was under the control of the medical staff. The hon. member moved that after the word "officers" the words "medical officers" be inserted. Mr. Childers could not consent to the proposed amendment, as in the first place the words proposed to be inserted were superfluous, the word "officers" including medical officers; and, in the second place, because the medical officers not being deprived of any advantage by the scheme, were not entitled to any benefit from it. Sir J. Pakington thought that engineers as well as medical officers were entitled to participate in the benefits of the scheme. Mr. Moore inquired whether the medical officers were to be excluded from sharing in the advantages of the hospital. Mr. Childers said they were to be included in the general word "officers." Sir F. Kelly said the Marine officers were expressly included in that list, while the medical officers were as expressly excluded from it. Notwithstanding the assurance the hon. gentleman had given them that medical officers were included in the general word "officers," some hon. gentlemen had doubts on the subject which might easily be removed by the two or three words necessary being inserted in the interpretation clause. Mr. Childers would take care that the wishes of the hon. and learned member should receive attention. Mr. Hennessy said that after the assurance of the junior lord of the Admiralty that the medical officers were included in the word "officers," he would withdraw his amendment. Lord A. Paget would be sorry if the hon. member withdrew his amendment, on the supposition that medical officers were intended to participate in the benefits of the scheme. Medical officers held appointments in the hospital at present,

and those appointments they would not be deprived of, so that, as they lost nothing by the scheme, they could not fairly hope to derive benefit from it.

HOMŒOPATHIC CANDIDATES. Dr. Tweedie's name was published as a member of the Committee appointed to further the election of Captain Grosvenor for Westminster. Thereupon he writes to the captain, wishing to learn whether or not the captain is a supporter of homœopathy. To his letter the captain returns the following curt and equivocal answer:—"Sir: Whenever I am ill—which, by the blessing of Providence, does not happen very often—I apply for advice and assistance to the doctor of my regiment, who is, to the best of my belief, a very orthodox practitioner. I am, etc., J. S. W. Grosvenor." To this note Dr. Tweedie rejoins by requesting that his name be withdrawn from the captain's Committee.

VACCINATION A FAILURE AND DELUSION! The Annual Conference of the British Medical Reform Association will be held at the Ram Inn, Sheep Street, Northampton, on June 8th, 1865. A public tea will be provided; tickets ninepence each. After which, a public meeting will be held at the Mechanics' Lecture Hall, when a lecture will be delivered by Thos. Stowell, M.D. (Brighton), Member of the Royal College of Surgeons, England; subject, "Small-pox, its History and supposed Antidote; Vaccination, its Origin and positive Failure; Vaccination superseded." Chair to be taken by John Skelton, jun., M.D. M.R.C.S.England. The meeting will also be addressed by Drs. Payne, Wortley, near Leeds; White, Leeds; Thomas, Newcastle-upon-Tyne; Hodgkins, Wolverhampton; Turnbull, L.R.C.S.Edin., L.R.C.P., Aberavon; S. Colmer, M.R.C.S.E., Yovil; and other friends. Admission free. Dr. Stowell has kindly consented to be consulted upon small-pox and other cases, on Friday morning, June 9th, at the Botanic Institute, 110, Bridge Street.

THE WOORALI POISON. The Woorali or curare poison forms the subject of an interesting paper by Dr. Claude Bernard, in a late number of the *Revue des Deux Mondes*. This poison, though harmless when introduced into the stomach, causes paralysis when thrown into the circulation. So certain is the deadly effect of this poison known to be, that when an Indian happens accidentally to wound himself with one of his own arrows, he simply lays himself down to die without making the slightest attempt to save himself; and, as death comes on without any visible struggle, it is universally believed that the victim suffers no pain. This notion, however, Dr. Claude Bernard shows to be erroneous. Paralysis creeps gradually on from limb to limb, depriving the animal of motion, but does not in the slightest degree affect the intellectual faculties or power of volition. Now this he considers to be one of the greatest tortures to which an intelligent being can be subjected. Dr. Claude Bernard shows that the proximate cause of the animal's death by woorali is by the gradual extension of paralysis to the respiratory organs; and shows also that the poisoned animal may be restored to life by artificial respiration. By this process time is given to the organs to eliminate the poison by the ordinary functions, so that in the course of a few hours the animal will recover. Another means of cure is a ligature effected above the wound, so as to prevent the poison from being carried to the heart by the circulation of the blood. The ligature may be alternately slackened and tightened, so as to allow small portions of the poison to penetrate into the bloodvessels by degrees, allowing time for each portion to be eliminated before another is admitted, and thus, in the course of about twelve hours, the whole of the poison is eliminated.

DEATH OF SIR JOHN RICHARDSON. Sir John Richardson was born in 1787, and was educated at the Grammar School of Dumfries, his native town. At fourteen years of age, he entered the University of Edinburgh, and applied himself assiduously to the study of medicine. In due course he entered the army as assistant-surgeon, and served at the siege of Copenhagen in 1807. In consequence of the great ability he displayed on that occasion, and "for having served in the boats during a night attack upon a French brig in the Tagus," he was promoted in 1808 to be acting surgeon of the *Hercules*, a 74-gun ship. During the war with the United States in Canada and Georgia, he served as surgeon to the 1st battalion of the Marines; and in 1819 accompanied Sir John Franklin's Arctic expedition as surgeon and naturalist. He also accompanied Sir John Franklin's second expedition in 1825, when he commanded two boats, in which he discovered the passage between the mouths of the Mackenzie and Coppermine Rivers. In 1838 he was appointed Physician to the Fleet, and Inspector of Hospitals in 1840. The deceased knight, who was a Fellow of the Royal Society, was the author of the *Fauna Borealis Americana*, the *Zoological Appendix* to Sir Edward Parry's second voyage, the *Ichthyology of the Voyage of the Erebus, the Terror, and the Sulphur*, and several reports and scientific papers. He received the honour of knighthood in 1846.

ODONTOLOGICAL SOCIETY. An ordinary monthly meeting of this Society was held on Monday, the 5th instant, at the Hospital, Soho Square; the President (Thomas Rogers, Esq.) in the chair. Mr. Coleman called the attention of the Society to a case in which torsion had been unsuccessful, owing to the spiral shape of the fang causing the tooth, when turned, to come out of the socket. Mr. Woodhouse said that his plan had been, never to attempt torsion after the tooth had been through more than a year. Dr. L. Levison read a paper on a few Human Skulls, as furnishing data in proof of the brain being under similar laws (organic) as induce the development or wasting of the muscular system. He said that, as most of these skulls were abnormal specimens, they furnished some suggestive explanations of certain forms of disease in the dental organs. Mr. Woodhouse read a paper, on the Use of Carbolic Acid in Dentistry. He stated that carbolic acid, in the operation of excavating a tooth for stopping, from its cauterising property, was exceedingly useful in rendering a fresh prepared surface of the cavity less sensitive before filling it. The acid was most useful in cases where the pulp was exposed, and where, without its aid, the general practice would be to destroy it. After describing the mode of treatment, Mr. Woodhouse read notes of cases prepared by Mr. Gibbons, in which the acid had been successfully applied to the treatment of sensitive dentine, exposed pulp, and alveolar abscess. A long and animated discussion followed, various members of Society narrating cases where the application of carbolic acid had been most successful.

A SENSIBLE JURY. Dr. Herapath has received the following flattering testimonial and an address in reference to his investigation of the Dawlish poisoning case. "Dawlish, June 7, 1865. My dear Sir,—On behalf of the foreman and ten of the remaining eleven gentlemen who sat on the late inquest, and twenty-seven other subscribers among the gentry and tradesmen of this little town, I have the pleasure of sending you a cheque for £5 as an earnest and testimony of your valuable and kindly volunteered services, together with the accompanying public address to you on the occasion, from the Daw-

lish Times. I am, dear sir, yours faithfully, J. G. HARDING. Dr. Bird Herapath, F.R.S." *The Address.* "We, the undersigned, foreman of the jury and jurymen, considering, as we do, that our coroner, although legally was scarcely morally justified in disallowing Dr. Bird Herapath's expenses, have hereby agreed to raise among our resident inhabitants a small sum as a testimonial, by way of thanks, to that gentleman. Dr. Bird Herapath was prepared with and showed the jury the result of a very elaborate analysis. Without his or other competent chemical assistance, the jury could not, and would not, have arrived at any result whatever. We are of opinion, that it is a bad precedent in the county of Devon to throw the entire onus of a *post mortem* scrutiny on any professional gentleman not chemically qualified as an expert in poisons. The 'labourer is certainly worthy of his hire'; and it is clear that, in many cases (if professional men are not to be paid), shortcomings and failures of justice will arise. We, the undersigned, issue therefore our protest—conceived in no offensive spirit—but as a matter of what seems to us justice and equity—feeling, as part of the community of Dawlish, that it is a reflection on our town, not to say the county, that an eminent toxicologist should have, of necessity, been referred to, and yet dismissed without any remuneration whatever."

DR. MACLAGAN. This good old man—who never made an enemy and never lost a friend—the valued family doctor and friend—the public-hearted citizen—the genial companion of our best men for fifty years—died on Tuesday evening—gathered into the garner of the great husbandman like a shock of corn fully ripe. His well-known person, his hearty smile and kindly greeting, have been missed from our streets for more than a year, and for some weeks he has been gently dying—*felix opportunitate mortis*, with his unfailing life-companion and her seven sons, an unbroken family, around his bed. Dr. MacLagan was born in Edinburgh, in February 1785. He took his degree in 1805; and, having resolved to join the medical service of the army, he went to London, studied at St. George's Hospital, and became a member of the Royal College of Surgeons of England in 1807. His first service was with the 91st Regiment. With the 91st he went, in 1809, to Walcheren, and had the mortification of seeing the splendid battalion to which he belonged reduced by death and sickness in a few weeks from a thousand men to something less than one effective company. In November 1811, he sailed for Lisbon, to join the army under Lord Wellington. He was appointed staff-surgeon to the 9th Portuguese Brigade, which he joined in the investing-ground before Badajoz. He continued to serve with the Fourth Division till September 1814. He was present at the storming of Badajoz, and at the battles of Salamanca, Vittoria, Pyrenees, Nivelle, and Nive; and, therefore, in due time received the Peninsular medal, with six clasps. His professional skill and ceaseless activity in the discharge of duty secured for him the most flattering expressions from all those under whom he served, including, among others, a special notice in an order of the day by Marshal Beresford, who praised him "for the promptitude and zeal displayed by him in the care of all the wounded, in having them accommodated and attended to, and their cases treated on the spot." The result of these distinguished services was his promotion to be Physician to the Forces, which rank he held when the Portuguese army went home from the campaign in France; and his return to England *via* Lisbon, instead of a more direct route, was owing to his detention by Sir Benjamin d'Urban, Quartermaster-General of the Portuguese

army, who stated that he valued Dr. MacLagan's services so highly "as to be obliged to make a point of retaining him to superintend the hospital arrangements of the Portuguese army." In 1816, having gone on half-pay, he settled in Edinburgh. From this period to his death, Dr. MacLagan is identified with his native city. He was elected President of the Royal College of Surgeons in 1826. In 1848 he became a Fellow of the Royal College of Physicians, and President in 1856. He thus had the unique honour of having been President of both the great medical incorporations of Edinburgh. Dr. MacLagan leaves seven sons. His eldest is our excellent Professor of Medical Jurisprudence; another, Colonel Robert, is a distinguished officer of Engineers. (*Scotsman.*)

UNIVERSITY OF CAMBRIDGE. The following were the questions proposed at the recent examination for the degree of Master in Surgery. *Surgical Anatomy*: 1. Describe the clavicle and its articulations. 2. Describe the shoulder-joint. In what direction is luxation most likely to happen? What parts are most liable to injury in this accident? 3. Name the bones of the tarsus. State the nature of their articulations; and describe briefly the ligaments of this part. 4. Describe the course and relations of the external carotid artery. When this vessel is to be tied near its origin, how is the incision to be made, and what parts are divided by it in succession? 5. Give the relations of the superficial veins and nerves at the bend of the elbow. How is the brachial artery placed at this part? 6. Define externally the position of the femoral artery where it passes under the superior border of the sartorius. In making the incision for applying a ligature to the artery a little above this point, what parts are successively divided? Point out the position of any veins or nerves that lie near the artery at this place. 7. Describe the spermatic canal. In the operation for strangulated hernia lying within the canal, what parts have to be divided? How may the spermatic cord and epigastric artery be placed with regard to the hernial sac? 8. Describe the nasal fossæ, and the arteries and nerves within them.—*Pathology, and the Principles and Practice of Surgery*: 1. What changes take place in a vein when it becomes varicose? Where does this most frequently occur? What ill consequences are likely to result from the varicose condition of a vein? 2. Describe the appearances which distinguish the various dislocations of the hip-joint, and state accurately the treatment suited to each. 3. The pathology of simple stricture. In what parts of the alimentary and urinary tracts does it most frequently occur? and in what parts does it not occur? 4. A man receives a severe injury to his head, what symptoms would be likely to follow it, and how would you treat the case? 5. In what respects does a cancerous tubercle of the skin differ from a scrofulous? 6. A woman has a tumour in the breast; by what symptoms would you be led to judge of its nature, and under what circumstances would you advise your patient to undergo an operation? 7. What are the sources of hæmaturia in the male? How would you discriminate between them? and what would be your treatment in each case? 8. Describe minutely the operation for inguinal hernie. What dangers have you to guard against? How would you avoid them?—*Midwifery*: 1. Describe the formation, structure, and functions of the placenta. 2. Describe any case you may have treated yourself of placenta prævia, stating the steps you adopted for the relief of your patient. 3. What symptoms would lead you to suspect that a woman was in the third month of pregnancy? 4. In head presentations give the various positions

relatively to the pelvis in which the head can be placed, and state the mode of rectifying a malposition where necessary. 5. In a case of protracted labour under what circumstances would you interfere, and how?—There were also examinations *visû vocæ* in surgery, anatomy, and midwifery, and by the bedside of the patients in the hospital, operations on the dead subject and specimens shown of healthy and morbid anatomy.

OPERATION DAYS AT THE HOSPITALS.

MONDAY.....Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY.....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY.....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopædic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY.....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY.....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY. Statistical Society.
WEDNESDAY. Geological.—Meteorological (Anniversary).
THURSDAY. Zoological.

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

S. J.—The correctness of the account of syphilisation given by us in the last number of the JOURNAL, is guaranteed by the fact, that it was perused and corrected by Professor Boeck himself.

RAILWAY ACCIDENTS.—Is there any reason given for the fact that, in the late railway accident on the South-Eastern Railway, eight of the ten persons killed were of the female sex? T. F.

THE FORMATION OF ETHICAL COMMITTEES.—SIR: In my communication to the JOURNAL (inserted on the 8th of April), respecting the formation of Ethical Committees by the Branches, it was implied, and it is believed, that the few independent Ethical Societies which now exist would not object to merge themselves in the Branches, were these Committees appointed. It is well known that several of these associations have admirably fulfilled the intention for which they were originally formed, and have rendered essential services to the profession.

Many of their members are also members of the British Medical Association; and the Branches would do well to secure the services and experience of some of these, by electing them on the Committees. I have no doubt many of them are prepared to hail with gratification the opening for a more extended field of action, whereby ethical principles and usages will be practically recognised and embraced by a great body of the profession.

The annual meeting of the Association being near at hand, it is hoped the members will be prepared to form an opinion whether the reasons adduced in this and my previous letter are not sufficiently strong to induce the Association to adopt the course I have recommended. I am, etc.

Manchester, June 8th, 1865.

AN OLD MEMBER.

[Why should not our respected correspondent himself bring forward a resolution on the subject at our annual meeting?]

EXAMINATIONS IN ARTS.—It may be interesting to students to know that there will be a preliminary examination at the Royal College of Surgeons on Tuesday next; and that gentlemen passing this ordeal, or a similar examination at the College of Physicians or Apothecaries' Hall, can enter on their hospital studies in October next.

SYPHILISATION.—The patient lately visited by Dr. Boeck, and operated on by him in Ireland, is, we believe, a very unfavourable case for the operation of syphilisation. The process is being carried out by Dr. Bidenkap, Dr. Boeck having returned to Christiania. Dr. Boeck gave evidence before the Veneral Commission on Friday, the 9th instant. His evidence was, we understand, taken in English, which he speaks imperfectly. Possibly, therefore, he may not have fully expressed his exact meaning on all the points touched on by him.

POOR-LAW MEDICAL REFORM.—SIR: I am sorry so frequently to trouble you, but events have transpired so unexpectedly during the last few weeks, that it has been unavoidable, and I must again crave your permission for space to inform all the Poor-law Medical Officers that a Poor-law Continuance Bill has been introduced into the House of Commons; and as I considered it would be a good opportunity to make a final attempt this session to amend the Medical Relief of the Poor, I have forwarded a pamphlet on the subject to each member of the House of Commons, urging them to insist on clauses being introduced into the Bill now before the House.

I should have sent a copy of the pamphlet to each Poor-law medical officer; but, as I am already in debt about £20, I do not feel justified in incurring further expense; but I have directed the printer to keep the type standing for a few days, to enable any gentleman to have a copy on forwarding six postage stamps to Mr. Sherren, printer, Weymouth, or to myself.

I sincerely trust that success will attend our efforts, and that the present Parliament will yet do us and the poor that justice for which we have so long toiled.

I trust every medical man in the kingdom, but especially the Poor-law medical officers, will, without delay, urge upon his member the necessity of Poor-law Medical Reform.

I am, etc., RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, June 10th, 1865.

SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

T. WATKIN WILLIAMS, General Secretary.

Birmingham, June 1865.

COMMUNICATIONS have been received from:—Dr. HENRY MARSHALL; Dr. P. W. LATHAM; Mr. T. M. STONE; Mr. J. Z. LAURENCE; Mr. R. FLINT; Dr. MACKESY; Dr. FALCONER; Dr. BRYAN; Dr. WATERS; Dr. WILLIAMS; Dr. J. R. WARDELL; Mr. RICHARD GRIFFIN; Mr. STEELE; Dr. PHILIPSON; THE SECRETARY OF THE ODONTOLOGICAL SOCIETY; Dr. HERAPATH; A MEMBER: Mr. W. J. COULSON; Dr. CHEVALLIER; and Mr. C. H. ROPER.

BOOKS RECEIVED.

1. Sea-Air and Sea-Bathing for Children and Invalids; their Properties, Uses, and Mode of Employment. By Dr. Brochard. Translated and Edited by Wm. Strange, M.D. London: 1865.
2. Der Croup. Von Dr. F. Pauli. Würzburg: 1865.
3. The Fourth Annual Report of the Glasgow Dispensary for Skin Diseases. Glasgow: 1865.
4. Chloroform; its Action and Administration. A Handbook. By Arthur F. Ernest Sansom, M.B. Lond. London: 1865.
5. The Student's Book of Cutaneous Medicine and Diseases of the Skin. By Erasmus Wilson, F.R.S. London: 1865.
6. Tension of the Eyeball; Glaucoma; etc. By James Voss Solomon. London: 1865.

Original Communications.

ON CATARRHAL OPHTHALMIA.

By HENRY HANCOCK, F.R.C.S.E., Senior Surgeon to the Charing Cross and Royal Westminster Ophthalmic Hospitals.

Most writers upon ophthalmic diseases describe catarrhal ophthalmia as a purely local affection, depending upon atmospheric changes, especially upon exposure to cold and wet, and essentially requiring local applications for its cure. I believe that this opinion is incorrect; that some other cause is requisite to produce this particular affection of the eyes, beyond those here mentioned; that there must, in fact, be a peculiar condition of system predisposing to this particular affection.

Were atmospheric changes, or exposure to wet and cold, alone sufficient, every inflammation of the eye depending upon these causes would necessarily be catarrhal. This, however, is by no means the case. In one, there may be simple conjunctivitis; in another, rheumatic scleritis; in a third, the inflammation will assume a gouty character; whilst, in the class of cases under consideration, it is catarrhal.

The patients most predisposed to catarrhal and its sister though more formidable diseases, purulent and gonorrhœal ophthalmia, are essentially those in a low and depressed condition of the system generally, analogous to that met with in erysipelas; and it is in this class of patients that we find catarrhal ophthalmia most prevalent. It is a perfect pest to the children confined in our large pauper establishments; it is a common companion or successor to the epidemics of low typhoid or typhus fevers which rage among distressed pauper populations. Indeed, it would seem that whatever tends to depress the nervous system, and to vitiate the blood, is a predisposing cause to this form of ophthalmia; and that, although the physical signs may be most apparent in the eyes, they are, in truth, local manifestations of general wrong, against which the treatment should be directed, rather than against the local manifestations themselves. Under these circumstances, I cannot agree with Mackenzie (4th edition, page 441) that, if catarrhal ophthalmia be treated only by general remedies, it will continue for many weeks, becoming the cause of much febrile excitement and constitutional illness, as well as of local distress and danger; or that the conjunctiva will become sarcomatous and rough (granular), and by rubbing, in this state, against the cornea, render it (especially the upper half of it) vascular and nebulous, or even densely opaque.

That the lids become granular after catarrhal ophthalmia, and that they in this condition affect the cornea as thus described, is unfortunately a fact of too frequent occurrence to be disputed; but I cannot admit either that treatment by general remedies solely will cause these lamentable results, or that "special remedies in this disease are inferior in importance to local ones." From many years' experience in the treatment of catarrhal ophthalmia by local astringents, such as nitrate of silver, sulphate of zinc, etc., I am convinced more frequently than otherwise, that their employment prolongs the complaint, and causes granulation of the lids. Freely admitting that bleeding, local or general, frequent doses of calomel, or any violent depleting remedies, do harm and should be avoided, as in erysipelas, I

have for some years past entirely restricted my treatment of catarrhal ophthalmia to constitutional remedies, for the most part of an attractive, a stimulating, and tonic character, merely directing the eyes to be fomented frequently with warm water, as much for the purpose of cleanliness as of comfort. I now very seldom see granular lids follow catarrhal inflammation; whilst the cure has certainly not been more protracted than when local applications were most successfully employed. The cases in which this treatment is most beneficial are those described by Mackenzie as "pure mucous or blenorrhœal inflammation of the conjunctiva;" in other words, in simple catarrhal inflammation—ophthalmia, *unaccompanied by supra- or circum-orbital pain*, and for the most part confined, at all events in its early stages, to the conjunctiva and the Meibomian follicles. In these, the disease mostly comes on suddenly, commencing with a sensation of itching and stiffness, speedily converted into a feeling as though grit or sand were in the eye. Upon examination, the eyelashes are found loaded with thickened glutinous mucus. The eyelashes are swollen, their lining conjunctiva being of a darkish red colour and flabby; whilst that of the eyeball, in the milder forms of the disease, is traversed by a network of vessels of the same dark red colour, which can readily be moved by pressing the lower lid against the eyeball, which in most instances is marked, especially at its lower half, by patches of extravasated blood, distinguishing this disease from the more acute and phlegmonous inflammation of the conjunctiva.

In its most simple form, the disease will be restricted to the angles of the lids and adjacent conjunctiva. When more severe, it will extend over the whole surface of the lids and eyeball; whilst, in still more severe and serious cases, the subconjunctival cellular tissue is infiltrated and raised, forming a distinct elevated fleshy ridge around the cornea, which appears sunken in, and at times partly obscured by irregular masses of swelling investing its surface, and constituting that condition termed chemosis. At the same time, the conjunctiva of the eyelids becoming in like manner infiltrated, the latter are puffed and swollen, creating difficulty of opening the lids, and in this way impeding vision.

Even when the amount of chemosis is considerable, the cornea for a time remains clear; but, if this condition exist for two or three days, it will become hazy, opaque, yellowish, and ultimately slough and give way, allowing the iris to protrude, resulting in more or less destruction of vision.

Lacrymation is always increased, the secretion being sometimes quite clear, at other times thick, yellowish, or muco-purulent. The symptoms towards night increase in severity; the intolerance of light is greater; the patient is feverish, and complains of pain and weight in the head, principally in the region of the frontal sinuses, and in the course of the lacrymal sac and ducts. These symptoms usually subside after the patient is quiet in bed; but they are sometimes so severe as entirely to prevent rest or sleep. In such cases, the Dover's powder or opium is of the greatest service, and will frequently cut short the attack. In ordinary cases, I give bark and ammonia; but, when the patient resides in a low damp locality, it may be necessary to give the sulphate of quinine in full doses, with or without opium, according to the intensity of the pain and the irritability of the patient; whilst the local applications should be restricted to warm water, or at most a poppy-head fomentation, to the exclusion of all local remedies of a stimulating or astringent character.

So long as the tongue is coated, and the breath foul and offensive, mild alterative aperients, such as

pilula hydrargyri, with *hyoscyamus* and extract of *colocyath*, are of great service, especially where there are chemosis of the conjunctiva, and tendency to opacity or sloughing of the cornea. In such cases, bleeding, whether local or general, violent purging, and local applications of a stimulating and astringent character, do considerable mischief; whilst, on the other hand, I have commonly seen the happiest results from mild alterative aperients—bark and ammonia or quinine, with or without opium, according to the amount of pain; with warm and soothing local applications.

That the disease, even in its most severe form, will yield, and yield rapidly, to constitutional remedies alone, is amply proved by the cases here subjoined.

CASE I. J. E. F., aged 8 months, was brought on October 10th, 1864, to the Royal Westminster Ophthalmic Hospital, suffering from catarrhal ophthalmia of both eyes, of one week's duration. The conjunctivæ were chemosed, and discharged profusely; and the eyelids were so much swollen that the child could not open his eyes.

R *Ammonia sesquicarb. gr. v; tinctura cinchonæ ʒi; decocti ejusdem ad ʒij. M. Sumat ʒij ter quotidie.*

The eyes and forehead over the frontal sinus were ordered to be frequently fomented with warm water.

Oct. 12th. He was very much improved. There was less discharge; and the swelling of the lids was so much reduced that he could now partially open his eyes.

R *Hydrargyri cum cretâ gr. iij; pulveris rhei gr. v. M. Fiat pulvis hora somni sumendus.*

The mixture was repeated, and the warm water continued.

Oct. 14th. The patient was going on well. The medicine was repeated.

Oct. 21st. He was now cured.

CASE II. J. M., aged 3, was brought in October 10th, 1864, with catarrhal ophthalmia of both eyes, of one week's duration. The symptoms were similar to those of the last case. Three drachms of the mixture of ammonia and cinchona (as in Case I) were given three times a day, and an alterative powder at bedtime; and warm water was applied as in the former case.

Oct. 12th. The child was much better. The mixture and warm water were continued.

Oct. 17th. All pain and discharge were gone. The chemosis of the conjunctiva and swelling of the eyelids had entirely disappeared. The patient was ordered to continue the treatment for two or three days longer. The child was finally dismissed cured.

CASE III. B. H., aged 16, applied October 12th, 1864, with catarrhal ophthalmia of both eyes, of four days' duration. She said she caught the complaint from a little brother. There was considerable congestion of the conjunctiva of both eyes, with the characteristic patches of extravasated blood. The discharge was but scanty. She stated that the attack came on suddenly; that she became worse towards night; and she complained of pain and weight in her head and forehead, especially over the frontal sinus, accompanied with some intolerance of light. The tongue was foul.

R *Pilula hydrargyri, extracti hyoscyami, extracti coloc. comp., sing. gr. iij. M. Fiat pilula hora somni sumenda.*

She was ordered to take an ounce of the ammonia and cinchona mixture three times a day, and to apply warm water frequently to the eyes and forehead.

Oct. 14th. She was better. There was less congestion, little or no discharge, and less pain and intolerance of light. The mixture was repeated.

This patient did not apply again.

CASE IV. H. B., aged 38, applied to Mr. Hancock October 17th, 1864, with catarrhal inflammation of both eyes, of five days' duration. The patient complained of great pain at night, and said that the attack came on suddenly. There was slight chemosis; profuse discharge; and the eyelids were much swollen. The ammonia and cinchona mixture was ordered to be taken in ounce doses three times a day.

Oct. 19th. There was no improvement. The mixture was repeated.

Oct. 21st. The patient was better. The eyes were less swollen; the pain and discharge much less. The mixture was repeated.

The patient continued to improve, and on the 28th was dismissed cured.

CASE V. J. C., aged 43, applied to Mr. Hancock October 24th, 1864, with a very severe attack of catarrhal inflammation of both eyes, of a week's duration, which he attributed to exposure to cold. He stated that the attack came on suddenly, with a feeling as of grit in the eyes. There was now profuse discharge, with severe pain at times. The conjunctiva was of a deep red colour; and the chemosis was so great that the cornea appeared sunken and overlapped at its circumference by the irregular surrounding swelling. The lids were also so much swollen that he could not open his eyes. He was ordered to take an ounce of the cinchona and ammonia mixture, also five grains of compound ipecacuanha powder, three times a day.

Oct. 26th. He was much better in every respect. The bowels were confined. He was ordered to take two cathartic pills at bedtime; and to repeat the mixture and omit the powder.

Oct. 28th. He was still improving. The treatment was continued.

Nov. 7th. He had gone on well to this day, and was now dismissed cured.

ON CERTAIN FUNCTIONAL DISEASES OF THE RETINA.*

By J. Z. LAURENCE, F.R.C.S., M.B.Univ. Lond., Surgeon to the Ophthalmic Hospital, Southwark.

BEFORE commencing the immediate subject of this communication, it will be well to define, as clearly as we can, what we are to understand by the term "functional disease."

All disease is, in a certain point of view, functional in its manifestation. For, where no disturbance of function exists, either to the patient's or to the physician's senses, disease can hardly be said to exist, if we except what is understood by the term "latent disease"—disease so subtle in its character, so impervious to either the patient's or the physician's observation, as to elude all outward detection. But the term "functional disease" has, by a kind of common assent for a considerable period, been construed in a limited sense to mean a perversion of vital action, manifesting itself in subjective or objective symptoms, inconsistent with health, but unaccompanied by any change of structure in the constituents of the body—so that, when this is subjected to the analysis of our senses, we are unable to detect in it any departure from those conditions which we are accustomed to meet with in the normal organism. This—so to say—vital etiology of disease played, in days gone by, an important part in the doctrines of the age; so much so, as to have even originated a distinct school of medicine—Van Helmont's school of Vitalism—a principle supposed to preside over

* Strictly, for the word "retina," I should have substituted all the nervous structures concerned in vision.

the body, and directly opposed to the influence of mechanical and chemical agents. But as our means of physically investigating disease have become multiplied and perfected, so has the number of the so-called diseases of function progressively decreased. Morbid changes, inappreciable to our unaided senses, have disclosed themselves to the analysis of instrumental appliances. The stethoscope, the ophthalmoscope, the laryngoscope, the microscope, and chemistry, have each taken an important share in detecting material changes in the organism in diseases, which had previously, from the want of such artificial assistance to our senses, been ranked amongst those of a functional nature.

There are, however, certain morbid states which we can hardly suppose to have any other than a purely functional origin. I may, for example, instance that of syncope. It would be an improbable ultra-speculation to suppose that the nervous centres undergo any material change of structure during a short faint, to as readily again acquire their original normal condition on recovery; although, even here, it is true, we are met by our certain knowledge of the extreme rapidity with which physiological processes of an undoubtedly material character—such as the oxygenation of the blood—take place under our very eyes; and, if a physiological process, why not a pathological? If we, then, take a broad view of the entire subject, we are irresistibly impelled to the conclusion that, sooner or later, when our present methods of research have arrived at greater perfection, or have become supplemented by others of increased refinement, the term “functional disease” will altogether vanish from the realms of medical science. However, it is in the nature of things that such a state of science is, at any rate as regards our generation, but an Utopian aspiration.

At present, then, we must remain satisfied by understanding, under the term “functional disease”, a disease which we, in our existing state of knowledge, have no means of connecting with any observed material change in the organism obvious to our unaided or aided senses; and it is in this limited signification that I employ the term functional, as applied to those conditions of the eye of which I am about to speak. Before, however, proceeding to the immediate subject of our investigation, let me draw attention to another important preliminary reflection.

In studying pathology, we must, I think, clearly separate two factors; viz., what we observe during life and what after death, using the word death in its limited sense to mean the extinction of life, whether it affect the whole or part of the body.

To illustrate what I mean, I may take a disease of the chest. During life we perceive a peculiar sound distinguished as fine crepitation, accompanied by dulness of percussion, and all the other concomitant physical and rational symptoms of pneumonia. I say “pneumonia”, because we have gained the right to this designation, not from the symptoms observed during life, but from inspection of the lungs after death. A certain set of symptoms has been observed in thousands of cases to accompany certain morbid changes in the lung-substance. We have, therefore, a perfect right to call that disease in which we observe this set of symptoms “pneumonia”, although we may never have had an opportunity, by the patient's death, of actually verifying our diagnosis by submitting the affected lungs to physical inspection. In the pathology of the eye, however, it will, as far as we can at present see, be ages before we can ever arrive at such a positive diagnosis; and the reason is obvious. It is because, out of the hundreds of eyes we examine with the ophthalmoscope,

we very rarely indeed ever have an opportunity of examining the organic changes that accompany the ophthalmoscopic appearances. It is all very well for authors to assign certain material morbid conditions to certain aspects of the fundus oculi; to say, *e.g.*, that whenever the optic nerve presents a dead-white, tendinous appearance, that then there exists atrophy of that nerve. I regard such names as names only—till ophthalmoscopic appearances have, by numerous dissections, been absolutely proved in an overwhelming number of cases to be connected with certain respective, material, anatomical changes. We may, however, with perfect justice, connect symptoms with ophthalmoscopic appearances. We may even go further, and very reasonably conceive the two to depend on certain morbid conditions; but we have no right to authoritatively and dogmatically lay down any inseparable connection between the two.

To recapitulate: in the following observations I shall designate by the term functional disease, a perversion of normal action, partially or wholly directly inexplicable by any organic changes in the eye, in our present state of knowledge, appreciable to our senses.

One of the most remarkable functional diseases of the retina is its paralysis. I have observed this taking place suddenly after a blow on or near the eye; the patient there and then, as far as I could ascertain, becoming partially or wholly blind, and, what is more, never recovering any further vision. These cases are so interesting, that I may be permitted to give the details of some that I have observed.

CASE I. A man was struck on the eye by a rocket-ball in 1854. Violent inflammation ensued at the time. I saw him about nine years after the accident. I then found he had simple perception of light. After a careful comparative ophthalmoscopic examination of both eyes, I could find nothing but a small black pigmentary deposit in the macula lutea of the blind eye.

CASE II. A young woman was struck by the cork of a ginger-beer bottle on the left eye. This set up inflammation in the eye, which lasted for about a week. I saw her about two months after the accident. She had never been able to distinguish even light from darkness since the accident. The pupil was somewhat dilated, but contracted slightly to light. A comparative ophthalmoscopic examination showed that, to all outward appearances, the fundi of both eyes were precisely similar and normal.

In the following case we have an instance of acute paralysis of the retina occurring idiopathically.

CASE III. Robert K., aged 32, an engineer, whilst in South America three years ago, had a paralytic stroke, from which he lost the use of the left side of his body, whilst the left side of his jaw “was locked”, and the tongue deviated to the left side. The right eye became totally blind and turned completely in; the left eye was not at all affected. He used galvanism; and, applying it for six months to the right temple, recovered the movements of the right eye. He is gradually recovering the use of his left side. Now the right globe is slightly divergent for distance; its movements perfect excepting inwards, he not being able to invert the corneal margin nearer than to about a line from the caruncle. He is stone-blind of this eye. Both optic entrances, vessels, etc., were perfectly alike in the two eyes, and apparently perfectly normal.

This case, however, is not one quite at point; for there was probably some deep central cause for the blindness.

In the above cases, then, we have sudden and complete abolition of useful sight, unaccompanied by any

appreciable organic changes in the retina or optic nerve entrance sufficient to account for the blindness.

A very remarkable series of cases are those in which a blow on a position corresponding to one of the branches of the fifth nerve has been followed by amaurosis.

Maekenzie, in his *Practical Treatise* (pp. 115-118), alludes to several such cases. "Petit submitted to the French Academy of Surgery the case of an officer who became completely amaurotic in consequence of a sword-wound in the eyebrow." Vicq d'Azyr had recourse to experiment. He laid bare, in a variety of animals, the frontal and superciliary branches of the fifth pair; he bruised and tore the exposed nerves; and convinced himself that this was speedily followed by blindness."

The following very striking instance occurred in my own practice.

CASE IV. A man, 38 years of age, was, eight days before I saw him, thrown forcibly against a broad piece of iron projecting from a mantel-shelf. He went at once to St. Bartholomew's Hospital. Much bleeding ensued; and for six days the lids were so swollen, as to prevent him from opening them. When he could do so, he found that he was quite blind of the eye. On examination, I observed half an inch below the left lower eyelid, and parallel with it a wound of the skin measuring three-quarters of an inch across. He said that it was here that the piece of iron struck him. The parts around the wound were red and thickened. The eye on the injured side stood about a line higher than the left eye, and was also slightly divergent. He had no perception of light with the eye. A comparative ophthalmoscopic examination of each eye disclosed not the slightest difference in either eye. In both the fundus was somewhat pale. A second such examination, twenty days afterwards, yielded the same results. On a third examination, a week later, I found signs of commencing atrophy of the optic nerve; it was paler in colour, and its contour more abrupt than that of the right eye. He had not recovered the slightest perception of light.

A case somewhat of the same kind came under my notice in the autumn of 1863. But, in this case, the eye of the opposite side to the injury of the face became amaurotic; in addition, changes of nutrition also set up in the eye.

CASE V. Ann B., aged 43, was, whilst walking along, struck by a brick falling from some buildings on the right side of her face. When I saw her a fortnight after this accident, there was a linear scar running pretty nearly in a line with the outer border of the right nasal bone. There was also a short scar down the dorsum of the nose below the bridge. She was stunned for an hour or so; and her nostrils, she said, bled. Two days after the accident, she noticed she could no longer read with the left eye, and subsequently the sight became much worse as if "a skin were before the eye." On examination, I found both eyeballs very prominent; the left eyeball as soft as a bag of water, the right one softish only; the left iris green and tremulous, the right one blue and not tremulous; both pupils acted well and independently to light; the corneæ were both equally sensitive; the optic entrance in the right eye appeared from some irregular refraction, distorted, and "floated" with each movement of the eye; the fundus oculi of the left eye was normal. She complained of a sensation of cold in the left eye. With the left eye she could not read c c (Snellen) at twenty feet; with an 11-inch concave lens, she read it at twenty-six inches. Her acuity of vision (S) with this eye was thus 1-100th; with the right eye, she read No. 23 (Jäger) at twenty feet with a 6-inch concave lens; and s therefore equalled 1-10th. I saw this patient

again on Jan. 31st, 1865. She had now lost all perception of light with the left eye; the lens had become opaque; the iris was bulged forwards; the pupil undilatable, even to atropine, its edge irregular. The eyeball was very tender, and "felt always cold" to her; the cornea was markedly less sensitive than in the other eye. She told me she had had a black eye from the injury.

There is one weak point in both the above cases that we have no right to disregard. In both, the patients had swelling and ecchymosis of the lids after the accident. I regard this, however, as not the direct result of the injury; but of the same nature as that which so frequently occurs at a distance from fractures of bones, or after the application of leeches in the proximity of loose integument. Under any circumstances, the absence of ophthalmoscopic signs in the blind eyes is a circumstance of great interest.

It is a remarkable fact that, in paralysis of the motor nerves of the extrinsic muscles of the eye, vision is rarely much, if at all, impaired. The very fact of the constant occurrence of double vision in these cases is sufficient to prove the general truth of this assertion. But minutely exact observations on this interesting subject, especially with reference to the state of the pupil and of vision, remain to be made.

How are we to interpret such cases as the above? For want of a better explanation, I at present call the blindness a reflex phenomenon. I conceive the blow on the branches of the fifth nerve to be conducted by them to the cerebrum, and hence reflected in a centrifugal direction by the optic nerve to the retina. In our present state of knowledge, I think we are justified in thus explaining such cases. In the action of the pupil to light, we have a physiological phenomenon of a similar nature, only that the conducting and reflecting nerves act here in a reversed order. The light stimulates the retina; this stimulus is transmitted to the sensorium by the optic nerve, and is hence reflected to the nerves of the iris.*

Such cases as those I have been recording are instances of what might be termed acute paralysis of the retina. They are not very common, but still occur every now and then. The following very interesting case may perhaps be considered an instance of a subacute form of paralysis of the retina; whether from pressure on the retina itself, or on its conductor to the sensorium, the optic nerve, I am not in a position to say.

CASE VI. Elizabeth P., aged 11, a very intelligent girl, stated that a fortnight before I saw her, she felt what she described as a "pinching" pain in the right eye and the right side of the forehead, and, on closing the left eye, she discovered that the sight of the right was dim. The pain had continued ever since; and the sight became progressively less and less, till she could barely distinguish light from darkness with the affected eye. To still further fix this point, I, by the prism test, convinced myself of the absence of all simulation of blindness. On her regarding a distant object, I observed the right eye was drawn somewhat outwards and upwards, and its power of inversion diminished; facts pointing to partial paralysis of the internal and inferior recti muscles. The right eye was also more prominent than the left one. On examining the two eyes ophthalmoscopically, I found them normal, and absolutely identical. She had suffered from periodic attacks of violent headache for three years, the last one being two months ago. The headaches would

* Fontana and De Ruiter have shown that the pupil does not contract, when a jet of light is thrown in the iris alone, without its entering the pupil.

last about four hours at a time, and were so violent as to make her cry. She had never had any fits. She subsequently had an attack of what her general medical attendant, Dr. Jeffree of Kennington, considered meningitis; and after this she completely recovered the vision of the affected eye. I, at the onset, diagnosed the amaurosis as depending on some effusion within the orbit pressing on the optic nerve or retina; and I consider the ultimate progress of the case justifies me in adhering to this diagnosis.

[To be continued.]

CARCINOMA OF THE STOMACH.

By JOHN RICHARD WARDELL, M.D., M.R.C.P., Physician to the Tunbridge Wells Infirmary.

THE following cases are not given as presenting any very peculiar characteristics of the above named disease; but rather as a fair illustration of its examples which are ordinarily met with in practice.

CASE I. I was requested, by Dr. Johnson of this place, to see with him, January 28th, 1863, Mr. S., who had for some weeks previously been under his care. The patient was head gardener to a gentleman residing in the neighbourhood; and he had regularly pursued his occupation up to the time of the more urgent symptoms of his illness. He was now, and had been for some days, confined to his bed. He was 51 years of age, and had always been a healthy man until about two years prior to the above date, when he first began to experience what he conceived to be merely impaired digestion, for which the ordinary remedies had been employed. During the summer of 1862, he had been slightly jaundiced. Subsequent to that affection, he had abscess of the liver, which opened externally; and for some months a sinus remained, from which a small quantity of purulent matter continued to escape.

At my first visit, he had a cachectic look, was much emaciated, and then laboured under persistent sickness and vomiting; the ejections being sour, and a biliary mucous fluid. The respirations were not accelerated; percussion over the thorax generally elicited the clear pulmonic notes; and auscultation proclaimed no abnormal sounds. The pulse was 92, small, compressible, and regular; the cardiac impulse weak, not diffused; there was no valvular disease. On carefully percussing the hepatic region, dulness manifestly extended over a less space than natural; the abdomen was so distended with flatus that now palpation could detect no abnormalities of the viscera. Pressure at the epigastrium gave acute pain; and he described this pain as "sharp and shooting". The bowels were regular; and, when they were moved, only small amounts of fecal matter were voided. The urine was of specific gravity 1020; no morbid products were detected on the application of ordinary tests. He had had a variety of tonic and stomachic medicines without any material benefit. He had taken the bitter infusions, mineral acids, bismuth, quinine, oxide of silver, prussic acid, aloes, and belladonna, and other remedies of a similar kind. On a general review of the case, and when the tympany existed, the diagnosis could be but a doubtful one. The solution of morphia, with hydrocyanic acid, were agreed upon, to be taken at short intervals; and concentrated beef-tea, with port wine, every two hours. Under this treatment, the sickness was for a time relieved.

I saw him with Dr. Johnson again in the course of another week. The tympanitis had now subsided; and, on again examining the abdomen, we could feel an irregular hard lump, of about the size of a small

orange, at the right epigastric region, corresponding with the situation of the pyloric orifice. It was now abundantly clear, from this fact, the history, and the whole of the accompanying symptoms, that this was a case of carcinoma. He continued to waste and decline in strength; the sickness, vomiting, and epigastric pain, being to the last persistent and predominant symptoms.

He died February 14th, 1864. No inspection was made.

CASE II. The next example of this disease was in the person of Mrs. D. who, Oct. 16, 1863, came from a distance to consult me. Her case was reported as being one of stricture of the œsophagus. She was 49 years of age, married; her countenance was dusky, yellowish, anæmic-looking; the volume of flesh was considerably reduced. About two years before, she had first begun to experience pain at the epigastrium immediately after taking food. Her affection had been regarded by an hospital physician as dyspepsia, and by a general practitioner as mere indigestion; for which a great variety of remedies had been tried, yet with little real benefit. The loss of flesh and strength, anorexia, with occasional vomiting, becoming more and more pronounced, and the opinion having been given that the disease was stricture of the œsophagus, herself and friends became alarmed, and my advice was requested. Three months prior to my seeing her, she had had, from time to time, attacks of vomiting almost immediately after a meal, and the ejected matters were invariably sour.

When I saw her, she said the swallowed morsel always produced pain, and it "felt as if it stuck very low down", on which account she had been compelled to live on fluid or on semi-fluid diet. The tongue was clean, smooth, and red; and the papillæ, even at the V-shaped circumvallate lines, were almost indistinct. Her bowels were regular; pulse small and weak, 92. Percussion and auscultation gave no indication of thoracic disease. The abdomen, on palpation, gave no evidence of lesion, except at a circumscribed place at the epigastric region between the mesian line and the anterior border of the left false ribs. Over this space even moderate pressure gave great increase of pain. Pressure could be borne at the right side of the epigastrium. She said the pain was always in one place; that she could cover it with the palm of the hand; that it was a "sharp, pricking, wringing, sometimes a burning, pain." Her husband and daughter, who drove over with her, were much concerned at her inability to swallow solids, and were afraid of death by starvation. I softened an œsophagus bougie in hot water, oiled it well, and very cautiously introduced it. Not the slightest resistance was felt until its end reached the cardiac orifice, where there was slight obstruction; but excessive pain was produced, which was felt through into her back. The instrument was at once withdrawn, the object not being dilatation, but a mere help to diagnosis. From the history, symptoms, and all the circumstances, I did not hesitate to pronounce the case as being a fatal one. On careful manipulation, some thickening of the cardiac end of the stomach could be felt through the attenuated parietes. It was a plain case of carcinoma. I ordered pills, with extract of belladonna, aqueous extract of aloes, and quina; and a belladonna and opium plaster to the epigastrium. I also directed her to have new milk, thickened with some farinaceous article of diet; concentrated beef-tea, with isinglass, tapioca, and port wine. The pain increased in intensity; her flesh and strength decreased; sour vomiting became more frequent; and the desire for food less and less; the difficulty of taking it greater;

and she gradually sank on December 16th, about two years and three months from the commencement of her illness.

CASE III. I was desired by Dr. Johnson, May 16th, 1863, to see a patient who for three months previously had been under his care. He was a tall, powerful man, 55 years of age, of florid complexion, who, twelve months before this date, had enjoyed good health. He then began to labour under a sense of pain and fullness at the epigastrium, but he did not for some time subsequently seek advice. In Feb. 1863, he consulted Dr. Johnson, who treated his case in the ordinary manner when such symptoms are exemplified. He had given to him, from time to time, a variety of stomachic medicines, which were followed by some temporary improvement. But he did not make progress, and my own opinion was asked. When I first saw him, the pulse was 78, volume good, and regular. The physical signs of the thoracic organs were natural. The tongue was covered with a thin creamy coat; his appetite was impaired; the bowels were inclined to be confined, necessitating the occasional use of some aperient. On examining the abdomen, the epigastrium was full, rounded, and preternaturally resonant on percussion. Pressure over this region, at the mesial line and towards the left hypochondrium, gave pain which extended into the left back. He placed his fingers on the precise spot, which "felt tender." No tumour, nor well defined hardness, could be detected. The kidneys acted normally. The urine was of specific gravity 1020; no morbid products were found, except excess of triple-phosphates. He had latterly become desponding, and was easily fatigued. It was now impossible to say, whether it was or was not malignant disease. There was yet no great wasting; nor had he the cachectic expression. He had hydrocyanic acid, strychnine, aloes, extract of opium, extract of belladonna, belladonna plaster to the epigastrium, and like remedies, with a carefully regulated diet. He improved for a time; but the pain, which was of the stabbing kind, never entirely removed. He made no real progress; and he was recommended to go to Brighton, where he remained a month. On his return, he was thinner; and the face began to wear a haggard, sharper expression. Nitrate of silver, extract of conium, decoction of cinchona, and dilute nitric acid, were given; and morphia at bed-time. He had more pain after meals; the vomiting matters ejected were always sour. He was ordered to have a liniment of camphor, extract of belladonna, tincture of opium, and chloroform, to be applied to the epigastrium.

Now (Sept. 20th), we believed in the existence of malignant disease. The loss of flesh was rapid; the pain sharp and lancinating; the vomitings more frequent. He was recommended to consult Dr. Brinton; and, at Dr. Johnson's request, I wrote a short account of the case. That gentleman's reply was as follows.

"I have examined Mr. — very carefully; and, on the whole, fear your opinion is only too correct. At least, I find considerable thickening of the stomach near its cardiac end; and surmise that a certain degree of softening and abrasion of the mucous membrane, if not some downright ulceration, is present here. At the same time, it is quite possible that these symptoms and appearances may be due to mere ulceration without a markedly cancerous deposit. Even in the latter case, I should hope much may be done (as I have certainly found in cases with peculiarities analogous to this) to relieve his sufferings and defer the result. The prescription and diet concur in essentials with the plan already pursued." (The prescription was for pills, with extract of colo-

cynth and extract of belladonna, and quina; strong soups and farinaceous food for diet.)

During the next three months, all the symptoms were more pronounced. Emaciation went on; strength rapidly declined; he had pain without intermission; the sour vomitings soon after meals became more frequent; and the nature of the malady was only too obvious. At the epigastric region, to the left of the mesial line and towards the hypochondrium, there was resistive hardness, and even moderate pressure increased the pain. Morphia was given every night. The bowels were opened on alternate days by enemata. Lime-water or milk were given to relieve excessive acidity. Having to go to London on Jan. 24th, 1864, he wished to consult Dr. Budd. Again, at Dr. Johnson's request, I wrote a concise detail of the case. Dr. Budd replied as follows.

"I agree with you and Dr. Johnson that the disease under which Mr. — is suffering is malignant. The gastric symptoms and the loss of flesh are such as usually betoken malignant disease; and in the left epigastric region (to which you directed my attention) an irregular lump can be felt. I would recommend a light diet, some soothing medicines, such as chloric ether, hydrocyanic acid, and tincture of calumba, bicarbonate of potash, or Vichy water; a belladonna plaster over the epigastrium; morphia every night; and occasionally a colocynth or aloetic pill."

In the course of another month, he became confined to the house. The opiates required to be very considerably increased. The emaciation became at length extreme. Port wine, brandy, iced champagne, concentrated beef-tea, for a short time extended his existence; and he died March 12th.

CASE IV. J. T., aged 64, a thin anæmic-looking man, for many years had been in declining health. This gentleman told me that five years previously he began to experience much disorder in the stomach and bowels; the former frequently giving considerable pain; the latter being irregular in their action, with much tendency to be confined. He placed himself under my care March 25th, 1864. He had been treated by several practitioners, yet without deriving more than temporary benefit. He looked languid and haggard, the countenance always being expressive of suffering. The physical signs of the heart and lungs were normal. Pulse 76, soft, regular. He had pain at the right iliac fossa, described as lancinating and shooting up into the right back; also some pain on pressure at the epigastrium. He could lie on either side, but was most free from pain when standing. When he sat down or went to bed, the epigastric pain increased. Hence, at my visits, I generally found him walking about the room; and he would say, "I am tolerably easy when erect." When pressed at the right hypogastrium, pain was experienced; and percussion gave dulness, which, however, from time to time differed in extent and intensity. He was much troubled with flatus; and the bowels were rarely moved, except by artificial means. There was no disease of the bladder; the urine was normal both in quantity and characteristics. His appetite was impaired and capricious; he had now no sickness or vomiting. I ordered him nitrate of bismuth with infusion of calumba and tincture of henbane. The mineral acids, morphia, extract of belladonna, aqueous extract of aloes, quinine, were given; and epithems, with belladonna, opium, and chloroform; and a diet selected of the most digestible and nourishing articles, as pounded meat, new milk, eggs, concentrated soups, jellies, and the like; wine and brandy in small quantities. Under this treatment, he for a time seemed to rally; his appetite was better; he slept longer; and he had more hope; yet

the cachectic look was still present. There was a continuous loss of flesh, and the epigastric pain never entirely ceased. On November 5th, persistent sickness and vomiting supervened; the ejections were a sour muco-biliary fluid, accompanied with much pain at epigastrium, extending down into the right hypogastrium. I ordered hydrocyanic acid and solution of morphia, anodyne fomentations, and opiate enema. Iced champagne and concentrated soups were given in small quantities and at frequent intervals, as soon as they could be retained. He had a repetition of these distressing attacks, some of which continued for many hours. He gradually but surely lost ground. The appetite declined; he became more and more feeble and attenuated; pain, sickness, and vomiting being the predominant symptoms to the last. He died December 5th.

SECTIO CADAVERIS, December 7th, twenty-four hours after death. Dr. Davy, house-surgeon to the infirmary, kindly made the autopsy. The body was greatly emaciated. On opening the abdomen, the omentum was found reddish, vascular, and divested of its ordinary amount of fat. There was no excess of serum; no traces of inflammation in any organs inspected *in situ*. The peritoneum was quite healthy. The liver was small, yellowish, fawn-coloured, and softer than normal to the touch. On making repeated sections of its parenchyma, a nutmeg appearance was exhibited, more especially towards the borders; and this condition was associated with the fatty change. Microscopic examination showed the hepatic cells to be engorged with oil-drops; and the latter, of smaller size, were seen crowded together in grape-like clusters. Both kidneys were lobulated; the capsules could be stripped off without preternatural adhesions. Longitudinal sections of each kidney showed the pelvis and calyces to be filled with fat. The cones in some places had lost their normal configurations; and in some parts the cortical substance had become thin and diminished. The pancreas, duodenum, jejunum, ileum, colon, and rectum were healthy. There was no trace of disease at the ileo-caecal junction, as anticipated during life. The bladder was healthy. The stomach, when manipulated before its removal, gave abundant evidence of lesion. A hard, irregular, resisting substance was felt at the lesser curvature. The organ being removed and laid open, some dark biliary grumous fluid was discovered in its cavity. Attached to the line of the smaller curvature was a large, irregular, nodulated, jelly-like mass, which extended between the cardiac and pyloric orifices; but both these orifices were quite exempt from disease. On making sections of this tumour, it presented a whity-greyish mottled appearance, with distinct fibroid striations vertical to the axis of the canal; and this fibroid substance contained variously sized loculi which were filled with transparent and semi-transparent gelatiniform exudations. The base of this growth was hard and dense, its density increasing in a ratio with its approach to the peritoneum; it was confounded and incorporated with the filamentous and muscular tissues proper to the organ; and, when regarded at its peritoneal aspect in certain places, its irregularities had a rough tuberculated appearance. Reviewed as a whole, it formed an apt example of scirrhus-colloid cancer, so often discovered in its favourite *habitat*, the stomach. Juice expressed from a thin slice, and placed under the microscope, contained very numerous nucleated, non-nucleated, caudate, and fusiform cells; and interspersed were resplendent fat-molecules, all of which constitute the characteristic products of an heterologous or malignant growth.

Transactions of Branches.

BATH AND BRISTOL BRANCH.

ON THE HYPODERMIC INJECTION OF MORPHIA.

By H. W. FREEMAN, Esq., Resident Medical Officer to the Bath United Hospital.

[Read May 18th, 1865.]

I BEG to submit, briefly, to your kind consideration, a few remarks on the action, use, and mode of administration of morphia when given subcutaneously.

I do not aspire to lay anything markedly original before you, but merely to give in the abstract a few observations of the hypodermic method in certain forms of disease in comparison with the usual effects of the drug when taken by the stomach.

It is just ten years ago since Dr. Alexander Wood of Edinburgh first introduced the injection of morphia into the cellular tissue of a part affected with neuralgia. Since that period it has been used extensively on the continent and in our own country, not only locally, but generally; the injection of the drug at a remote part of the body has not been found to materially alter its properties.

The endowed cancer ward of the Middlesex Hospital has, perhaps, afforded as large a field for the observation of its effect as most metropolitan institutions of its kind; and in, perhaps, but few hospitals has the hypodermic method of morphia received so fair and impartial a trial in all varieties of cases, both medical and surgical. Long since it has stood alone as the great remedy for pain in those malignant forms of disease, no other class of remedies seeming so efficacious.

The most convenient form of injection is that by a syringe made by Coxeter, which is graduated into six minims. The standard solution used at University College and the Middlesex Hospital is a neutral one, and prepared so that six minims contain a grain of morphia. Sufficient acetic acid is used to dissolve the salt, and afterwards neutralised with liquor potassæ. The physiological action is the same essentially, although not quite identically, as when the morphia is taken by the stomach. Its effects, however, are more marked and increased in intensity when used hypodermically, one-third of a grain acting as powerfully as one grain taken by the mouth, and much more rapidly. Much as with opium, the action appears to be modified by age, habit, temperament, and idiosyncrasy, the tendency always being to rapid alleviation of suffering, to stupor and to sleep. The stimulating stage, although brief, is marked, the patient first experiencing a sensation of slight vertigo and of approaching intoxication—then follow its calmative effects, and something approaching insensibility.

In illustration of the general phenomena, let me draw your attention for a moment to a case now under observation at the United Hospital, under the care of Dr. Falconer.

Louisa M., a middle-aged woman, is suffering from carcinoma of the pylorus, with intense pain, vomiting, and its usual accompanying symptoms. After giving her an injection into the outer side of her arm with a third of a grain, a minute and a half to two minutes elapse before its effects are first felt. She complains of a tipsy feel, slight giddiness, and warmth of body, with other pleasurable sensations. The calmative feeling gradually passes over her in from ten to twelve minutes, proceeding from above downwards,

and usually in fifteen minutes she is found sleeping. She remains in a state approaching torpor, and free from pain for a period averaging six to eight hours. Her pupils never markedly contract, and ten or twelve minutes elapse before any effect is produced on the irides. Her temperature rises 1° to $1\frac{1}{2}^{\circ}$ for the first hour after the injection, generally declining as the effects of the drug pass off. This patient has now been under this mode of treatment for upwards of three months; and, although the disease gradually creeps on, and the effects of the drug are transient, yet it remains clear that pain is relieved, her existence rendered less miserable, and her life has been prolonged.

In this case, as usually happens, forty to fifty minims of the solution of acetate of morphia have been given, and repeated at intervals without relieving pain or producing sleep. Since adopting the subcutaneous mode, her appetite, before much impaired, has much improved; the nausea and vomiting have been considerably relieved; and, after the narcotic action of the morphia, she rarely, if ever, complains of headache, constipation, nausea, sweating, or dryness of fauces. This is only one of a number of similar cases accompanied by the same phenomena, in which we notice the absence of the usual after-effects of opium and morphia when taken into the stomach, where becoming mixed with the various ingesta, they find their way slowly into the veins, and are probably in part decomposed in the stomach by its secretion, and are carried out of the system without having entered the circulation; while, if given subcutaneously, the full dose becomes absorbed, and produces its narcotic effects almost at once.

As a remedy in *neuralgia*, much has been written for and against subcutaneous injection. It has been urged that its action is transient, its power non-curative, generating nausea, and sickness, and producing a deplorable state of system, worse than the original mischief. A portion of this might hold true in some individual cases; the same exception might be taken to the general class of narcotics; but, in taking the majority of cases, I do not think we can fairly assume that such always occurs practically. Two brief cases, shewing its value in some cases of *neuralgia*, may prove interesting.

CASE I. Jane T., aged 24, was admitted into the United Hospital, under the care of Dr. Falconer, with subacute rheumatism of the lower extremities. The blister mode of treatment was adopted. She drew rapidly to convalescence, but got a relapse, with intense *neuralgia* affecting the intermuscular fibrous septa of the deep muscles of the thigh. A third of a grain of morphia was injected into the affected region. The usual phenomena were displayed, and within an hour she felt free from pain, and remained easy for three days. Symptoms of the same kind of pain were then experienced in the other thigh; a fourth of a grain was injected. She got rapidly well, pain disappeared, and within a week after the first injection she left the hospital. No other drug was administered during the treatment.

CASE II. Selina W., a hospital nurse, aged 20, also under the care of Dr. Falconer, was taken with rigors, pain in the limbs, and acute febricula with intense lumbar *neuralgia*. The prodromata of variola were predicted. The febrile symptoms, however, gradually subsided, but the *neuralgia* remained persistent. A fourth of a grain of morphia was injected into the outer side of the arm. The calmative effects of the narcotic were well developed for some time, and existed over many hours; she became very drowsy, and inclined to sleep. She recovered without a return of the *neuralgia* pain.

Both those patients were nervous, hysterical girls,

the latter stont and plethoric. Nausea was slightly complained of by one; no headache by either; no dryness of throat, or anorexia; and no subsequent return of the disorder. In those two cases we might observe that the pain was in each purely neuralgic, *unconnected* with any organic disease, or with any known irritation in any distant parts of the body; the effect of the drug being the same on each, although in one applied to the affected spot, the other at a distance in the arm.

Within the province of ophthalmic surgery, subcutaneous injections of morphia have been found of the most signal use.

Some papers of Professor von Gräfe, which appeared in the JOURNAL of the Association a half year since, went to show the individual merit of atropine and morphine injected about the orbit for wounds of the cornea, ciliary neuroses, iritis or glaucomatous, and for various forms of neuralgia and reflex spasms, due to corneitis occurring traumatically or idiopathically. He said that the use of atropine by injection was very limited; to relieve pain, and to produce its mydriatic effect, it is preferable to drop it on the conjunctiva, unless the eye will not tolerate its presence. In neuralgia of the eye, atropine injected appears quite inert. Morphine I have seen repeatedly prove invaluable. A case in point occurred under my own observation whilst ophthalmic assistant to Mr. Soelberg Wells at the Middlesex Hospital.

Fanny B., a markedly strumous girl of 16, was admitted with granular lids, which had produced corneitis and pannus, accompanied with intense photophobia, lacrymation, and ciliary neurosis with excessive spasm of the orbicularis palpebrarum. It was impossible to get a glimpse of the eyeball unless chloroform were used. Atropine and belladonna were subsequently applied to the conjunctivæ for six weeks. No progress took place; spasm and the hyperæsthesia remained intense. It was found, however, on making pressure over each supraorbital nerve as it escaped from its notch, that the lids could be slightly separated; and as the supraorbital nerve gives off some few filaments to the upper lid, and the spasm being thought to be reflex, it was suggested to divide the nerve externally to the notch. Happily the injection of morphia over the brow was adopted; and within forty-eight hours, two injections, each one-sixth of a grain, having been given, the girl could partially open her lids without much distress, the hyperæsthesia daily became less with a nightly injection, and in a week or ten days she could see to read No. 8 of Jäger's test-types.

To further enhance the value of the hypodermic injection of morphia in a surgical point of view, it has been but recently discovered how marked are its effects in prolonging the anæsthesia of chloroform, by injecting from a *third* to *half* a grain of the narcotic before the patient becomes quite sensible to external impressions.

It is just a year ago since the *Versailles Medical Society* first published their interesting researches on this subject of prolongation of anæsthesia. 1. Their conclusions went to show that five to ten centigrammes of morphia injected alone without chloroform produced a kind of intoxication, going on to torpor, but not giving rise to insensibility, properly so called. 2. Salt of morphia injected during the anæsthesia of chloroform prolonged its duration in proportion to the quantity employed. 3. Although the experiments were performed on dogs, yet it might be used without danger on man, more especially when the duration of an operation gives rise to fears in continuing the anæsthesia by means of chloroform. Three months ago, a second series of experiments, made on dogs, went to support the sur-

gical view, which was quite correct, and to show that injection might be employed without risk.

For upwards of two years past, all capital operations at the Middlesex Hospital have been treated in this way. All the amputations, ovariectomies, herniotomies, for the most part, have received from a third to half a grain of morphia subcutaneously immediately after the operation, and in the majority with good effect; and modern surgery knows how valuable it is in a practical point of view, to calm the nervous agitation of patients after operation, to lessen shock, to procure sleep, and, more especially in ovariectomies and herniotomies, to keep the stomach in a state of physiological rest for some hours afterwards. In those latter two classes of operation, nothing seems to do so well. Nausea might be induced; but whether from shock, chloroform, or morphia, is, perhaps, not quite clear; but, judging from the usual phenomena, it would be fair therapeutically to assume that most probably it arose from the effects of the chloroform, seeing that the after-injection of morphia entailed no such symptoms. Allow me to mention two cases, recently under observation, to bear out this fact.

CASE I. Sarah S., aged 40, was operated on by Mr. De Morgan for ovariectomy; the operation lasted twenty-eight minutes. Half a grain of morphia was subcutaneously given when the chloroform anaesthesia was subsiding. Some spasm occurred during the operation, and continued for an hour or so subsequently. At the end of three hours, a third of a grain was repeated, and again four hours after. After the second dose, no tendency to sickness supervened; the patient became placid, and remained in a state of stupor. Some good sleep followed, and she awoke refreshed.

CASE II. Caroline C. had amputation of thigh performed by Mr. Charles Moore; the operation lasted sixteen to seventeen minutes. Half a grain of morphia was given subcutaneously. She became quiet; dozed for six hours; and had no sickness for twenty-four hours. The morphia was repeated with good effect; and the patient made a good recovery.

The opportunity will not allow me to trespass further in detail upon the valuable time of the Society; but the numerous cases treated in almost every metropolitan hospital by subcutaneous injection of morphia where opium is indicated would be too long to enter upon here. The great obstetrician Scanzoni lauds it in the puerperal stage, and more particularly in puerperal convulsion. From personal observation in cases of tetanus, delirium tremens, and mania, more especially in cases of carcinoma of uterus and stomach, to relieve pain instantly—although, perhaps, it must be acknowledged, but temporarily—it stands alone. And hospital experience goes to show that, although it has to be administered frequently and in gradually increasing doses in those chronic malignant states, yet we seem to possess no drug better suited for those peculiar cases; and no drug, when given subcutaneously for a lengthened period, perhaps of many months' duration, produces seemingly so little after ill-effect upon the human economy.

To compare the narcotic action of atropine hypodermically, with the like administration of morphia, is but to compare the therapeutical value of opium and belladonna as narcotics. The effect of atropine might be much more lasting, less transient, than morphia; yet the latter exerts its influence almost instantaneously. The use of belladonna must consequently be more limited in daily practice; and if its use be persisted in for any length of time, the probable atropial phenomenon, its liability to frantic excitement and gay delirium, with its own peculiar effects on the

human system, would contra-indicate its continuance.

Atropine, as belladonna, relieves *par excellence* superficial pain. Morphia, as opium, relieves internal deep seated pain. Yet, in this mode of administering morphia, it cannot be looked upon with impunity, knowing how great and powerful are its effects; and consequently great caution and a certain amount of discrimination are demanded in its administration.

Opium, inadmissible in some varied forms of disease, would be doubly inadmissible as morphia given subcutaneously. Opium is inadmissible in advanced stages of phthisis, in old standing cases of chronic bronchitis, or where the air-passages, loaded with profuse secretion, can scarcely be evacuated; and here morphia given subcutaneously, in a moderately large dose, would kill very rapidly; the tendency not being only to diminish the secretion, but to paralyse the action of the mucous passages in eliminating the secretion. The wheezing dyspnoea of dry asthma would scarcely come within the category.

Habit, it appears, modifies the effects of morphia given subcutaneously; the dose requiring to be gradually increased, yet not so quickly as if taken by the stomach. Many a cancer patient in the wards of the Middlesex Hospital takes from two to three grains daily hypodermically, equalling six to nine grains of crude morphia taken by the stomach. Yet no other remedy seems to answer so well.

It might seem probable, that the frequent introduction of the perforating tube of the syringe into the cellular tissue would cause abscess or erysipelas; but, cautiously applied, it rarely does so. Most of the long standing cases of carcinoma present areas covered with traces of the perforating nozzle, so as not to allow space for its repetition; and although the surface be tender, yet I have never seen either abscess or inflammation supervening. I have never seen or heard of harm being produced by this powerful remedy; yet I have witnessed results which, when it has been cautiously administered, have been as much satisfactory and astounding to the observer, as they have afforded comfort and alleviation of suffering to the observed.

CASE OF EXCISION OF THE UPPER JAW.

By HENRY MARSHALL, M.D., F.R.C.S.Ed., Clifton.

[Read May 18, 1865.]

THE subject of the following case, M. B., aged 59, is a single woman, a native of Monmouthshire, and resident there. She was recommended to my care by Mr. Morgan of Newport, on account of a tumour of the left maxillary bone.

I saw her for the first time on April 12th; and found the cheek on the affected side to be fuller and larger than the other, produced by a firm tumour, which was tender on pressure. On looking into the mouth, I found all the teeth in the upper jaw absent, and a swelling of the gum on the left side, extending over part of the hard palate, as far as, but not beyond, the mesial line. An ulcerated opening existed in the gum, through which a probe might be passed into the antrum; but not without producing an inconvenient amount of hæmorrhage.

She stated that she first became aware of a small lump "like a gum-boil" in the left upper gum, about the beginning of last year (1864). It gave her no trouble or inconvenience, and was supposed to arise from the stump of a decayed tooth, until September of the same year, when it suddenly became very painful and increased in size, ulcerated, and emitted a very offensive discharge. This swelling gradually, but steadily, increased; and in December she consulted Mr. Morgan.

By this time, the tumour had encroached upon the palate; while there was a discharge of offensive matter from the nose, and the left nostril had become stuffed.

Mr. Morgan made an incision into the tumour, which was followed by rather free hamorrhage; and up to the time of my seeing her, she frequently suffered from its spontaneous recurrence.

Being of opinion, that the excision of the superior maxillary bone offered the only hope of relief from the disease, and having obtained her consent to undergo the operation, I advised her entering the Bristol General Hospital, to which course she agreed, and was admitted under my care on April 20th.

Two days after (April 22nd), having put her fully under the influence of chloroform, I made an incision through the cheek from the zygomatic process of the malar bone downwards in a slightly curved direction to the angle of the mouth, the convexity of the curve looking downwards and backwards. Then raising upwards and inwards the flaps of soft parts from the bone, and detaching the ala of the nose from the maxillary and nasal bones, I divided with cutting pliers the superior maxillary bone at its junction with the malar; then placing one blade of the pliers in the orbit and the other in the nose, divided the nasal process of the maxillary bone. I cut through the hard palate a little to the right of the mesial line by similar means, and then wrenched out the bone from its remaining connections. Not a single vessel required to be tied.

Having placed some pieces of folded lint into the cavity, I brought the edges of the wound together by means of a hare-lip pin at the angle of the mouth, and of a few silver wire sutures.

On examination of the bone which had been removed, the antrum was found distended by a grey gelatinous tumour, of an obviously malignant character.

The patient hardly suffered any constitutional disturbance, and passed a good night without the assistance of a sedative.

All the sutures were removed by the end of the fourth day, the wound having united throughout by first intention. She rapidly recovered her strength; and was able to sit up ten days after the operation, and to leave the hospital on May 11th, just nineteen days after the operation. There is now scarcely any difference externally between the two sides of the face.

In performing the operation, I followed the directions laid down by Mr. Syme, to whom the credit is due of having been the first to put a case on record of complete extirpation of the upper jaw, as well as of having introduced the most simple rules for its performance. Most surgical works in this country attribute the first performance of the operation to the late Mr. Lizards. Although, in his *Anatomical Plates* published in 1826, this surgeon suggested the operation, the first case in which he performed it was in August 1829; while Mr. Syme had removed the entire superior maxillary bone two or three months previously, in a case which was published in the *Edinburgh Medical and Surgical Journal* of the same year. In the following year, M. Gensoul of Lyons published a treatise on removal of the upper jaw, from which it appeared that he had performed the operation as early as 1827, although he did not make it public until 1830.

DR. PERCY'S METALLURGY has been translated into French by two engineers, MM. Petigand and Rouna, who have added special information from French sources.

Reviews and Notices.

MANUAL OF THE TURKISH BATH. Heat a Mode of Cure and a Source of Strength for Men and Animals. From Writings of Mr. URQUHART, edited by Sir JOHN FIFE, M.D., F.R.C.S., Senior Surgeon to the Newcastle Infirmary. Pp. 419. London: 1865.

IN the preface to this work, Sir JOHN FIFE informs us that the Turkish Bath has been, since 1859, used in the Newcastle Infirmary with great success in the treatment of various diseases; the average number of cases treated each day being fifteen. It is the conviction of the utility of this agent, confirmed by the benefits he has observed to follow its use, that has induced him to father this miscellaneous collection, mainly consisting of writings of the gentleman who has been the chief advocate of the introduction of the bath. In doing this, he observes that

"It is necessary, in the first instance, to guard against any hasty conclusions on the one hand, or, on the other hand, the rejection of statements that may seem at variance with the therapeutic science of men experienced in the value, and justly confident in the indications, that therapeutics afford.

"The same persevering confidence which enabled the author to effect the restoration to us of this Greek and Roman luxury may be well excused in regarding the Turkish Bath as a panacea; because without such a faith in its powers no one could have laboured so long, or have made the sacrifices required to revive this institution, buried for nearly a thousand years."

We infer from these remarks, that Sir John Fife does not pledge himself to the adoption of all the opinions expressed by Mr. Urquhart, but that he is desirous of placing before the profession the views held by that gentleman, in order that they may be tested by experience and judicious reasoning.

The contents of the book are various. First, we find the *verbatim* report of a Dialogue held on July 27th, 1860, on the subject of "Heat; how useful for Man, and how used by him." There are said to have been present "between thirty and forty medical and professional gentlemen and others;" and among the speakers were, besides Mr. Urquhart, Mr. Witt, Mr. E. Wilson, and Dr. Sibson. The principal *dramatis personæ* are Mr. Urquhart and Mr. Wilson, well known as a zealous advocate of the Turkish bath; and the points discussed are, the importance of "bringing the skin into action, and so evoking its latent powers as the means of reinvigorating the constitution and throwing off disease;" the action of heat independently of that of the skin; endosmose and exosmose; electricity; and actinism.

After this follows a Second Dialogue, headed "The Medical Society at Riversdale." In February 1861, Dr. Thudichum, at that time an out-and-out advocate of the Turkish bath, read a paper on the subject before the Medical Society of London. The reading of the paper was followed by a discussion, in which, while the value of the bath as a remedial agent was not denied, considerable scepticism was expressed as to the advantage of using it to the extent advocated by Dr. Thudichum. Mr. Urquhart, who was present, invited the members of the Society to visit him at his country residence; and, on February

25th, the invitation was accepted by, *inter alios*, Dr. Druitt, Dr. Thudichum, Dr. Leared, and Dr. Rogers. A very interesting discussion—interrupted by a visit to Mr. Urquhart's bath—took place. In the *verbatim* record of it which is here given, the reader will find a full account of Mr. Urquhart's views—often of a very extraordinary nature—on heat, clothing, diet, etc.; the sum and substance, as usual, being that the Turkish bath is a panacea for “all the ills to which flesh is heir”—provided that it be properly used. It is rather curious to observe that he claims, as an example of the good effects of the Turkish bath, Mr. Banting, “the type of obesity”; who, in a letter written to Mr. Urquhart in 1861, says:

“I have striven against obesity for near twenty years unsuccessfully. Through the baths alone (thirty-seven in three months) I am reduced in girth many inches, and in weight 5 lbs.”

Mr. Urquhart thinks the “5 lbs.” must be a mistake for “35 lbs.”—why, we know not. But, if the bath were so efficacious in 1861, what had become of its effect on Mr. Banting's obesity when he last year proclaimed to the world the *dietetic system* by which he had been happily able to reduce his inconvenient bulk? Appended to this dialogue are the following notes: Description of the Bath of Riverside (Mr. Urquhart's residence), by Mr. E. Wilson; the Bath of the Finns, from *Travels of Acerbi in 1798-9*; Waste of Fuel in England; Clothing not requisite in our Climate; Dyspepsia treated by one Meal a Day; and Medical Treatment of Rheumatism.

We find next a paper on the Art of Constructing a Turkish Bath, and its Economy as a Means of Cleanliness, read before the Society of Arts in February 1862. Then follows a Lecture delivered at Newcastle-on-Tyne in 1861, on the question, Why does Man Perspire? The next chapter is headed, Consumption produced by Habits, not by Climate. Next there is a paper by Dr. Leared on the Treatment of Phthisis by the Turkish Bath, reprinted from the *Lancet*; a letter by Dr. Thudichum on the Contents of Perspiration as Discharging the Matter of Disease; observations on Cancer, Leprosy, Hydrophobia, and Apoplexy, with notes of various special cases; a correspondence between Mr. Urquhart and Sir John Fife on the Construction of a Bath; a chapter on the Introduction of the Bath into the Lunatic Asylums and the Naval and Military Hospitals; and remarks on Heat-Rays, Sun-Rays, Electricity, and Vital Power.

The book is concluded with some remarks on the application of the Turkish Bath to Animals.

This outline of the contents will show that the materials of which the book consists are very varied; and, indeed, the reader will find in it a most interesting collection of what can be said about the Turkish bath, from the vagaries, mingled with some sound sense and important suggestions, of Mr. Urquhart, to the rational observations of Dr. Lockhart Robertson and other men of his stamp. Sir John Fife has acted with the best intentions in allowing himself to appear as the sponsor of this book. He has had ample evidence in the Newcastle Infirmary of the benefit derivable from the use of the Turkish bath—or rather, to adopt the words of the title and Mr. Urquhart's ideas, of heat in the cure of disease; and, so far, we understand him to be desirous of

bearing testimony to the value of the remedial agent whose use Mr. Urquhart has been so active in persuading his countrymen to adopt. In his preface, as has been seen, Sir John Fife attempts to excuse the extravagant expectations of Mr. Urquhart; and from this it is to be inferred that he does not endorse them. Nor can we suppose that he endorses the erroneous ideas which Mr. Urquhart expresses here and there as to the manner in which the Turkish bath has been received by the medical profession. Let us give an example or two.

On page 120, at the end of the Dialogue between Mr. Urquhart and the members of the Medical Society of London (1861), we find the following footnote.

“About this time a fierce war was waged against the bath by the medical journals. In replying to one of these, Dr. Thudichum wrote as follows:—‘The public in this matter is far in advance of the medical profession. Our duty, as doctors of the healing art, simply is, to make ourselves acquainted with the use of this therapeutic instrument.’”

The letter of Dr. Thudichum, from which the foregoing extract was taken, was sent to the *BRITISH MEDICAL JOURNAL*, and was published in the number for March 16, 1861, page 291. The leading article—the declaration of “fierce war”—to which it was intended as a reply, appeared at page 231 of the number for March 2; and in it occurred the following expressions.

“As a therapeutic agent the bath is, undoubtedly, worthy of much praise; and, certainly, we needed not this Turkish sudatory to tell us of the virtues of hot air, as applied to the external surface of the body in disease. We may, nevertheless, gladly avail ourselves of it as an extended and ready means of applying the agent. Gladly would we see the bath taken up by our hospitals. . . . What is now wanting, is a series of careful observations upon the effects of hot air in the cure of individuals suffering from different diseases; and there is abundance of evidence of the value of the bath as a powerful remedial agent to justify, or rather to oblige, our large medical institutions to make the Turkish bath an important item of their instruments of cure.”

This is from an article which, according to Mr. Urquhart, breathes “fierce war” against the use of the Turkish bath!

Again, at page 251 of the book, Mr. Urquhart, in speaking of the discussion in the Medical Society of London and the subsequent visit of several Fellows of that Society to his establishment, says that at the Society

“Twelve medical men, not one of whom had ever been in a bath or knew anything about it, spoke successively, giving utterance to opinions and asserting them with a confidence which could only be the result of the reverse of knowledge.”

And, a few lines further on, he says that not one of them appeared among his visitors; although, as he has learnt, “the most eloquent on that occasion—Dr. Richardson—has since become a convert.”

On referring to the notes of the discussion given in this *JOURNAL* (February 2nd, 1861, page 127), we find that several of the speakers brought forward instances of ill effects which they had observed to follow the use of the Turkish bath; while one—the late Dr. James Bird—stated that he had himself used the bath, and had derived great benefit from it.

Others, too, had seen it used. As to Dr. Richardson's "conversion", on turning to his paper published in the *JOURNAL* of the same date (page 114), we find that his "conversion" must have preceded the time at which Mr. Urquhart supposes it to have taken place. Here is an extract from his paper.

"Practically, in my own hands, I have seen benefit follow the use of heated air. I have known, for example, a hot-air bath improvised in cases of scarlatina, and I believe that in all cases where sweating was produced much good was done; but this is by no means a new remedy in this country.

"Since Turkish baths have been erected, I have sent to them cases of every kind that were likely, in my opinion, to be relieved by diaphoresis; and, in the main, the results have been good."

Mr. Urquhart must be more accurate in his statement of simple matters of fact, if he wishes his expressions of doctrine on more philosophical subjects to be accepted. It is not by misinterpreting the opinions of medical men in the manner to which we have referred, that he will impress on the profession a sense of the benefits derivable from the Turkish bath.

We sincerely trust that the very injudicious remarks sometimes made by Mr. Urquhart will not have the effect of deterring the medical profession from instituting an extended and a fair trial of the therapeutic value of the Turkish bath. To him is undoubtedly due the merit of having forced the subject on public attention; and, as far as scientific observation has gone, there is no question that in the Turkish bath, properly applied to proper cases, medicine has in its hands a most valuable remedy. What is wanted, we said four years ago, is a careful study of its effects. Since that time, it has been tried in several large institutions, but still not so extensively as it deserves. To the medical staff of the Newcastle-on-Tyne Infirmary especial praise is due for what they have done in this direction; and, if they (in conjunction with the staff of other hospitals and of lunatic asylums) would lay before the profession the results of the experiments which have been carried on by them during the last five or six years, they would—notwithstanding the very interesting character of the volume before us—produce a *Manual of the Turkish Bath* which would be a trustworthy guide to the use of this agent, and would produce far more conversions to the recognition of its value than volumes of extravagant laudation.

LECTURES ON NURSING: Short Notes addressed to Nurses. By J. C. LORY MARSH, M.D. Second Edition. London: 1865.

THIS unassuming little volume contains much information valuable for the purposes of those who are engaged in nursing. The necessity of an improvement in our nursing system has been of late years felt all over the kingdom. The ignorance of those to whom we have been contented to commit the care of our patients is very often not only destructive of their comfort, but even fatally prejudicial to their recovery. Unfortunately, we are as yet only on the threshold of this most needed reform in the management of the sick, as any one will readily see who reads the requirements of a proper nurse here given in Dr. LORY MARSH'S lectures. The importance of the nurse has practically not yet been fully appreci-

ated; and yet we doctors well know that the life of the patient is often far more in the hands of the nurse than it is in the hands of the doctor. For example, in cases of fever, what avail all the minute directions of the physician, if there be not an intelligent and *honest* nurse at hand to carry them out? We are glad to see an experienced physician like Dr. Marsh aiding in this good work by giving, in plain language, plain and useful directions on nursing.

THE WORKS OF SIR BENJAMIN COLLINS BRODIE, Bart., D.C.L., Sergeant-Surgeon to the Queen, President of the Royal Society, etc.; with an AUTOBIOGRAPHY. Collated or arranged by CHAS. HAWKINS, F.R.C.S.Eng. In Three Volumes. London: 1865.

MR. CHARLES HAWKINS modestly declines to call himself the editor of these volumes. He does not consider that the works of Sir B. BRODIE "require editing; his language needs no explanations or elucidations." And, he adds, that his long and intimate acquaintance with Sir B. Brodie "renders him unfit to make a juridical estimate of his character." In a preface, therefore, he prefers recording what was thought of Sir B. Brodie by others.

We cannot, of course, pretend to give any review of these volumes; but shall content ourselves with pointing out their main contents.

The first volume contains an Autobiography, of which we shall give our readers extracts from time to time; Psychological Inquiries, in two parts, the same having been published just before the author's death; Lectures given by him at the Royal College of Surgeons, when Professor there; the Hunterian Oration; Introductory Addresses delivered at St. George's Hospital; Addresses as President of the Medical Societies, of the Ethnological Society, of the Society for Promoting Social Science, and of the Royal Society; Articles on Quackery from the *Quarterly Review*, on Homœopathy from *Fraser's Magazine*, on Tobacco from the *Times*; and a Letter on Special Hospitals.

The second volume contains all papers of Sir B. Brodie's printed in the *Philosophical Transactions*, and a Croonian Lecture, which by the author's request was not printed at the time, and is now first published by Mr. Hawkins; the Works on Diseases of the Joints and on Diseases of the Urinary Organs, to which is added the paper on Lithotripsy from the *Medico-Chirurgical Transactions*.

The third volume contains papers published by Sir B. Brodie in the *Medico-Chirurgical Transactions* and other journals; Lectures given at St. George's Hospital on Pathology and Surgery, including those on Local Nervous Affections; and, lastly, Pathological and Surgical Observations on forty different subjects, which were dictated by the author during the last winter of his life, when he had his early notes of cases read over to him, his sight then not allowing him to read or write.

CHLOROFORM: ITS ACTION AND ADMINISTRATION. A Handbook. By ARTHUR E. SANSOM, M.B. Lond. Pp. 192. London: 1865.

THIS volume contains a very good and sensible summary of the history of chloroform, of its discovery, action, and application. The author appears to us

to have fully mastered his subject, and to have produced, in a very convenient form, a volume wherein the practitioner of medicine may obtain at once information on all the various details required to be known by those who undertake the administration of chloroform.

British Medical Journal.

SATURDAY, JUNE 24TH, 1865.

THE COLLEGE OF SURGEONS.

THAT the position assumed by this JOURNAL, in reference to the management of the College of Surgeons, should not be to the taste of all members of the Council, we can readily believe. One kind of objection, however, which has been thrown at us, we most distinctly demur to. It has been stated that we are interfering with matters which do not concern us, and which are the proper business of the Council only. Also, it has been said that we have incorrectly stated the case against the College management. Ever since this JOURNAL undertook an inquiry into the doings of the College, these things have been said. But the fact is, that no single one of the statements made by us has ever been disproved; and we believe that no one of them is capable of being disproved.

This JOURNAL, it must be remembered, was the first to investigate seriously the management of the College, to show its unsuitableness, and to demand its reformation; and we think we may fairly claim from the profession no small amount of thanks for having now for several years consistently and persistently prosecuted the question—not making it a matter of narrow personal interests, but arguing it on the broad and general basis of the rights and interests of the profession at large. From the very first, we pointed out the evils and demanded the reform, which we now point out and still demand; but with this difference, that at the present moment the reform is manifestly near at hand. When we first demanded a vote by written papers for country Fellows, we were laughed at. When we first demanded that Examiners should have no seat in the Council, we were laughed at. When we demanded that Examiners should be elected by merit out of the whole body of Fellows, we were also laughed at. But now all this is altered. Now candidates for the Council appear on the platform, pledged to support all these innovations! Could any greater illustration of the correctness of the views adopted and steadily pursued by us in this very important matter be given? We beg to tender this fact—the fact, that candidates of the highest position in the profession, who now offer themselves for a seat in Council, actually, as a passport to the

seat, pledge themselves to carry out in Council the very reforms which we have for several years past been urging and enforcing upon the attention of the profession—we beg, we say, to tender this fact as our answer to gentlemen who assert that we have unfairly and untruly dealt with the Council. And it is in support of these principles, that we strongly urge the election of Mr. Turner and of Mr. Charles Hawkins. Both these gentlemen have but one sole object in view—viz., as Councillors, to do the work of the Council. Neither of them has any aspiring for an Examinership. Both have long conscientiously supported the principles which we here maintain, and are not converts by compulsion on the eve of an election.

Next week, we will give a general summary of the actual state of the College management, and inquire if it be a management which is suitable to the age in which we live, and just to the profession whose interests are so deeply mixed up with it.

ELECTION OF FELLOWS OF THE ROYAL SOCIETY.

A NOTE from a correspondent, concerning the election of Fellows of the Royal Society, published at another page, is suggestive of much that regards the interests of the medical profession, and therefore deserves our best attention. The allegation of favouritism in the elections of the Royal Society does not, however, seem to be fully justified. There may be some slight reform desirable in the mode of nominating the officers of the Society; but we venture to state, from information on which we can rely, that nothing can be fairer than the selection of the candidates. There is always a very grave and even anxious investigation into the scientific attainments of every one of them; and a fair selection is made, so as to represent every branch of science. Our correspondent has probably not taken into account the new scientific professions which have sprung up within a very short period. The naval and military professions, to begin with, which were once merely defenders of their country in active service, have now been obliged to become conversant with all the scientific topics of the day, so as to apply all new discoveries to the purposes of war. Even more than this, they are employed by the Government in scientific pursuits. Engineer officers are taking observations to ascertain the figure of the earth; meteorologists are working to develop principles which may lead to the establishment of one of the most practical of sciences; and naval architecture and nautical magnetism are being energetically pushed forward. Another newly created class of scientific men is to be found in the civil engineers; and there is still another class who make pure philosophy

their profession. All these make a large influx of new candidates to compete for admission with the medical profession, who were once almost exclusively engaged in inquiries into the laws of Nature. Regrets, therefore, as to the diminished proportion of medical men in the elections of the Royal Society, when only fifteen new Fellows are annually selected by the Council, are hardly called for. The apprehension hinted at, not only by our correspondent, but also in other quarters, that there is a general depreciation of our profession, whether in the general estimate of its scientific character, or as to its social position, is a topic to which we may refer hereafter, when we shall not deny that, whatever may be the wider bearings of the question, a certain amount of injustice is meted to us at the present moment. We must rest in the meantime in the trite but true reflection, that it is useless as well as unwise to complain of an injustice which belongs to human character and attaches to all human institutions; while we venture to remind our readers that it becomes all truly and highly educated men, especially those trained in the ancient universities, who most feel the pressure of a political and German partiality, to trust more to their own industry and pure love of science, and to value more the estimation of the scientific world than those preferences which are bestowed through foreign courtly influence. This influence, together with new experiments in education, though they will probably prevail during the present generation, must in time give place to justice and common sense.

NAVAL SURGEONS.

BEYOND the ordinary dangers to men who are dependent on the will of irresponsible boards, in pointing out the errors of administration that oppress themselves, our brethren of the army and navy labour under most un-English restrictions, intended to prevent appeal to public opinion, and to prohibit combination for the purpose of making joint remonstrance against injustice to individuals or of improving the position of a class.

This pernicious system can only be justified in war times. During peace, it is certain, that the more the weak point of our systems of defence and offence are examined, the more probability there is that they will be strengthened.

This policy of suppression of opinion and truth is a very short-sighted one, when applied to the medical profession employed by the Crown; and is, indeed, powerless to effect the desired object: for it is impossible to prevent our independent medical press from making known the grievances and vexations suffered by the army and navy medical officers. In fact, we think that much less of acrimony and dislike would creep out if open discussion were allowed, and officers could, in safety, avow their productions.

At the time when the Royal College of Physicians

of London has decided on taking action in behalf of these services, happily for the Royal Navy medical officers, a former colleague of theirs, and a highly respected member of our Association,* has stepped into the field to do for the navy what it cannot do for itself; *i.e.*, to ventilate the ground of complaint, and to explain what he believes to be necessary for the restoration of the navy to that popularity it once enjoyed with our profession.

Dr. Brown has shewn that, in very many particulars of emoluments, and notably in that of honorary distinctions, the Medical Service of the Navy is very far in the rear of the Army Medical Service; and he then very justly claims for the navy an equalisation on all points.

The real cause of this special injury to the Naval Service, Dr. Brown ascribes to the paramount influence of one class of officers at the Board of Admiralty, where every question of medical interest is received through the medium of an officer of the executive class—the Medical Director-General having no direct relationship with the Board. This fact alone will account for the *mala fides* that, Dr. Brown states, has been persevered in towards our profession through this century.

As the result of this antagonism of sections, it has come to pass that the Naval Service is without candidates, even of an inferior class; so that the Medical Service is so far virtually at a stand-still. To remedy this state of things, Dr. Brown demands for the navy medical officers that equality with the army medical officers which was granted, at the instigation of Lord Nelson, by Order in Council, 1805, and again by Order in Council, 1859; neither of which has been carried into effect. Discouraged by this continued and successful opposition to authorised claims of equality, Dr. Brown considers that the naval medical profession can look to Parliament alone for redress of wrongs so long endured.

We sincerely recommend Dr. Brown's admirable and forcible exposition to the consideration of the profession; trusting that, in the coming elections, they will lose no opportunity of impressing on candidates for Parliamentary honours, the necessity for the exertion of the authority of Parliament once more, in order to establish the State Medical Services on a satisfactory footing; so that there may be no necessity to remedy such an evil under the pressure of impending war.

One word more of advice let us give to those junior members of the profession who may be thinking of entering the Navy or Army Services; and it will be the advice which *Punch* once gave to people about to marry—"Don't do it." If our profession would only for a short time join in a resolution to obtain their rights, how easily they would be gained. If

* *Requisitions of the Naval Medical Officers.* By F. J. Brown, M.D., etc., formerly Assistant-Surgeon in the Royal Navy.

men would only abstain a very short time from entering the Army and Navy Medical Services, all their grievances would at once vanish.

WHAT IS THE NUTRITIVE VALUE OF BEEF-TEA?

WE dare say some of our readers may remember an anecdote told of a famous *chef de cuisine*. When asked by his noble master how he managed to use so many hams—some thirty or forty—for a single dinner, he gave the unanswerable reply: “Milor, I shall put them all into no bigger as my thumb!” What really went with the hams we can only guess; but we may safely affirm that the whole of the nutritive matter of the thirty hams was not employed for his lordship’s benefit. And the anecdote recurs to us in considering the subject of M. Liebig’s *Extractum Carnis*. Can the scientific chemist, any more than the accomplished *chef de cuisine*, concentrate in his extract all the most highly nutritive matter of the meat? We cannot but think that the profession is labouring under some very grievous error in reference to the use of beef-tea and extract of flesh. We would, indeed, like to suggest for the consideration of our brethren a few plain questions on the subject. Are there before us any plain and satisfactory data from which we may obtain an idea of the real value of these extracts of flesh? Do we really know what amount of nutritive material we are administering to our patients, when we give them ordinary beef-tea? May we not be deluding ourselves in this respect? Is it possible to substitute effectively *Extractum Carnis Liebigii* for the *caro* itself? What is the real amount of nutritive material extracted from a pound of flesh? What is the relative value, as nutritive materials, of a pound of beef, and of a pint of beef-tea extracted from that pound? Is it not (so far as we have any proof to the contrary) just possible that a dog fed solely on beef-tea would perish as rapidly as if he were fed only on water? Have we, as physicians, really any scientific knowledge at all concerning the actual nutritive power of this beef-tea, in the fabrication of which, as we have said, in one hospital alone in London, some 52,000 pounds of meat are annually consumed? Can any one give us anything approaching to a correct answer of such a question as the following? What is the relative nutritive value of 52,000 pints of beef-tea, and of the remains of the 52,000 pounds of meat out of which they were made? We venture to say, *à priori*, on the strength of the most patent scientific facts, that these remains, forming the great bulk of the beef, and consisting wholly of fibrinous and albuminous matters, contain almost all the nutritive material of the beef. Yet this solid nutritive matter we throw away as waste, and at the same time flatter ourselves that in the pint of

beef-tea we have all the virtue and excellence of the pound of beef! A pint of beef-tea, made from a pound of beef after Liebig’s prescription, yields, on evaporation, something less than half an ounce of solid matter! This half-ounce of solid matter, therefore, be it what it may, represents the return in nutritive matter of the pound of beef.

We are satisfied that every one who calmly considers the questions here proposed will agree with us, that the whole matter is one which urgently demands a very careful and scientific inquiry, from two points of view—1. To ascertain what is the actual value as a nutriment of the beef-tea which is so universally given by us to our patients; and 2. To ascertain whether there does not exist in all our hospitals at the present moment an enormous waste of nutritive materials, in the shape of meat—the *bouilli*—which is thrown away or sold as refuse, after it has been used in the making of beef-tea—the *bouillon*. We believe that a competent commission, appointed to answer these questions, would do a very great service to our beef-tea fed patients, and would effect an immense saving in the consumption of meat in our hospitals; and, we may add, that we really do not know any source from whence authoritative information on the subject can be obtained.

Since writing these lines, we read in the *Dublin Medical Press* of June 14th, the following remarks, by a no less authority than Dr. Henry Kennedy. In a paper “On the Use of Barm and other Agents in the Treatment of Fever”, he says:

“As it would not be possible to consider here all the class of agents known as stimulants, I shall confine myself to two or three. And first amongst these may be placed wine and beef-tea, though the latter be not, strictly speaking, a stimulant, but which I constantly hear spoken of as if they were the same, and that where the one was used the other ought to be given with it. In a large number of cases of fever, however, they cannot be given together with advantage; and, paradoxical as it may seem, wine, in my experience, causes infinitely less risk than beef-tea, and here it is the principle I wish to elucidate is clearly seen, for the composition of these two fluids, it need scarcely be observed, is very different. In beef-tea, the quantity of fibrine, gelatine, etc., is considerable, and in proportion with the strength of the fluid. In wine, on the contrary, it is in very minute quantity; and besides, the latter has in addition most, if not all, the elements which enter into the formation of our frames. Of these, I might mention the alkalies and alkaline earths, fatty matter, sugar, albumen, traces of iron, malic, citric, and tannic acids, and all these again combined with more or less of a direct stimulant, in the shape of alcohol. Really, if with a knowledge of the component parts of our bodies, we then set about making a fluid suitable to a wasting sickness, it must necessarily have a composition like that of wine, which, it may be almost said, Nature has given us freely. Besides, too, all experience has proved its sustaining powers, for there can be no doubt that life will be supported by it for an almost unlimited period, and it is a positive fact that it will be taken often when all other kinds of food will be refused.”

We quote this passage, not so much for the purpose of giving Dr. Kennedy's opinion as to the value of wine, etc., in fever, but to illustrate the truth of the statement above made; viz., how little even hospital physicians know of the actual constitution and nutritive qualities of beef-tea. Dr. Kennedy here tells us, and assumes as one of the bases of his argument, that the "quantity of fibrine in beef-tea is considerable": whereas, beef-tea does not contain a particle of fibrine, inasmuch as fibrine is completely insoluble in water!

WE have been made aware, by prospectuses we have lately received, of an attempt that is now being made to revive, in a modified form, a practice which not very long ago aroused a tempest of indignation, without a parallel (so far as we know) in the social history of British medicine. It is but eleven years, as any one may see by a reference to our columns for 1854, since the medical brotherhood throughout the country was protesting with vehemence against the continuance of what was succinctly and very descriptively termed "the puff biographical." The profession was then startled—not to say scandalised—by the weekly appearance of the autobiographies of living men, many of whom took credit to themselves for qualities and public services which had not previously been heard of; while men of mark who refused their countenance to so disreputable a system, were either "damned with faint praise", or dismissed with a contemptuous snarl. How odious the transparent device was to the great mass of the medical community, was proved by the unanimity with which the second resolution of the Liverpool meeting was echoed from every quarter of the country:—"That this meeting disapproves of, and will discountenance by every means in its power, the publication of the biographies of living members of the profession." This resolution seems to us to place the question in its true light. It objects, not to the way in which the thing is done, but to the thing itself. It is quite true, that the present project is free from the most obnoxious features of the "puffs biographical" of 1854; and if it were possible to divest the proposed sketches of eminent medical men of everything objectionable, the able and accomplished editor is as likely as any one we know to accomplish the task. But that even he has his misgivings, is very plain from an apologetic paragraph which he has introduced in a second edition of his prospectus, by way of meeting the objections which some, we doubt not, have already urged, and of anticipating those which many others have yet in store for him. After so unequivocal a *pronunciamiento* as that of 1854, we cannot imagine that the profession will accept any apology for "Contemporary Biography", even under the "proper limita-

tions" and "necessary restrictions" contemplated by the editor, who, we trust, with his wonted sagacity, will pause before he plunges into "a sea of troubles", from which it would be no easy matter to extricate himself.

If we may judge from a letter which has been forwarded to us, something like an active canvass must be going on in behalf of candidates for the councillorship of the College of Surgeons. We do not for a moment accuse the gentleman on whose behalf the letter was written of being any party to the injudicious proceedings of his officious friend the writer; but we think it our duty to remonstrate against a practice which has always been condemned by the sentiment of the profession. The idea has, we believe, always been this: that those gentlemen-Fellows who are worthy of a seat in the Council must be sufficiently well known and appreciated in the profession, and cannot, therefore, require any of the dubious or fictitious aid which is often obtained by the canvasser's art. The letter we refer to is addressed to a Fellow, and is written by a Fellow, of the College. As regards the claims to consideration put forward by the writer in behalf of his friend, as the advocate in Council of certain liberal measures, we may remark that Fellows are now beginning to ask, How comes it that none of the things mentioned in this letter (and, by the way, we do not see among them voting by proxy) have been carried out? They do not stop to inquire with whom the obstruction rests. They reason only on the fact that nothing has been done, and they reason rightly; and, in accordance therewith, have, it would seem, determined, *pour encourager les autres*, to turn out every Councillor in rotation, until the spirit of the Charter has been carried into action. The Fellows have at last discovered their power, and are learning to exercise it. But what a victory is all this to us—that even Councillors should now be actually apologising for the *not* doing of those things which we have for years been demanding, and which we were once ridiculed for even suggesting!

THE idea of a "doctor" finding his way into Parliament could not be alluded to by the *Times* without a sneer.

"We observe that Mr. Clement, a medical candidate for Shrewsbury, rests his claims on somewhat analogous grounds. He urges, with some reason, that every profession but his own is duly represented in the House of Commons, whereas only one member of Parliament is a doctor. Perhaps the practical exclusion of physicians and surgeons may be justified sufficiently by the nature of their engagements; certainly it is not due to any jealousy on the part of their patients. If Sir Charles Locock and Mr. Clement shall find their way into the House of Commons, they may do good service in the discussion of sanitary measures; but they must first approve themselves as politicians to the electors of the Isle of Wight and Shrewsbury."

It is generally understood, that Mr. Ransome has no idea of going to the poll on the present occasion of election of Councillors at the College of Surgeons. Indeed, if we are rightly informed, Mr. Southam signed his paper on condition that he retired before the day of election.

Three cases of cerebro-spinal meningitis have lately presented in Oppolzer's clinical wards, and a few cases have been also observed in private practice in Vienna.

M. Payen, in his work on alimentary substances, speaks sensibly of the actual value of horse-flesh as an article of food. Animals (he says) which are destroyed on account of injuries received by them when vigorous and healthy, yield flesh of excellent edible quality. But accidents of the kind are rare; and most horses, when arrived at the full stop of their existence, are wasted and exhausted by work and disease; their flesh is tough and distasteful. Of course, feeding horses for the meat market is out of the question.

CEREBRO-SPINAL MENINGITIS.

DR. NIEMEYER gives the following as results of fifteen autopsies of cases of the epidemic cerebro-spinal meningitis, made at Karlsruhe, Rastalt, and Freiburg.

The bodies were but little wasted. Rigidity lasted a long time. Herpetic vesicles were often seen on the face and other parts, and in a few cases petechiæ. The dura mater was congested. The large vessels of the pia mater, and often also the smaller vessels, were distended with blood. In the subarachnoid space there was serous or purulent effusion. In most cases, the effusion was observed on the convexity of the hemispheres. The base of the brain and the upper surface of the cerebellum seem to have been attacked in all cases. The brain-substance was congested and softened. In the ventricles was a little coloured fluid, and in a few cases much purulent fluid. The vessels of the dura mater of the spinal cord were congested; the large veins were distended with blood. Under the dura mater was a large quantity of thick purulent fluid. The substance of the cord was softened, but not broken down. The lungs were congested. The lower part of the intestines was congested, with a few ecchymoses of the mucous membrane. In some cases, the solitary and Peyer's glands were swollen.

Of the symptoms, severe headache was the most constant. Pain in the neck and back soon followed the headache. Pressure on the spine increased the pain in many cases, but not in all. Pain in the extremities was not frequently observed. Hyperæsthesia of the skin occurred in most cases. Tetanic spasms of the muscles of the neck and back were present in almost every case. Convulsions were rarely seen. Paralysis of different parts of the extremities was frequently present; hemiplegia; in two cases, facial paralysis. There were great restlessness, jactitation, complaints of headache and delirium, often ending in coma. Deafness was frequent.

Ptosis of one or both eyelids was frequently noted; so also diplopia. The pupils were generally contracted. The pulse was rapid; the respiration disturbed and interrupted, deep and sighing, then becoming rapid. The bowels were generally much constipated. In some few cases, the urine was albuminous. On the skin were seen only a few patches of herpes, about the mouth chiefly. In one case, on the eighth day, was seen an exanthematous kind of urticaria; in many cases were scattered dark-coloured roseola spots, which passed into petechiæ. Febrile symptoms attended the beginning of the fever. Generally, without any warning, the patient would have shivering, with great headache and sickness. The headache would rapidly increase, the patient becoming very restless; the pupils contracted; the pulse 80 to 100, and the respiration 30 to 40. The heat of the body was moderate. At the end of the first or second day, and seldom later, the head was drawn backwards; and the pain extended down the neck and the back. There was great restlessness; the abdomen was sunken; the patient had constipation, wanderings, and contracted pupils; the pulse and breathing became rapid. On the third and fourth days, tetanic spasms of the neck and back, sometimes with trismus; marked opisthotonos. Deep sopor, unconsciousness, and death, followed. In those cases which recover, the restlessness and all the symptoms diminish; and, if the case go on well, all signs of disease disappear in a few days, and then follows a long convalescence.

Dr. Niemeyer regards the symptoms of the disease as distinctly connected with purulent inflammation of the pia mater of the brain and spinal cord. As to the prognosis; of 126 cases observed at Rastalt between December and April, 38 died, or 30 per cent. At Rastalt, the treatment consisted of ice applied to the head and back; leeches behind the ears; and internally calomel; with the subcutaneous injection of morphia to relieve the restlessness and jactitation.

Dr. Zuelchaur of Graudenz gives, in the *Berlin. Klinische Wochenschrift* of May 1st, his experience of cerebro-spinal meningitis. The disease (he says) has been epidemic at Graudenz for some weeks.

The patients (most of whom appear to have been children under 15 years of age) are suddenly seized with great pain in the head, which sometimes remits, and then soon returns worse than before. The pain is seated chiefly in the fore part and top of the head. In children, sometimes, it is accompanied with unconsciousness. Sickness soon follows. A few hours later, pain comes in the nape of the neck (and in one case preceded the headache), so that the patient can no longer move the head freely; the head is drawn backwards, and at the same time the shoulders are drawn together, so that the patient, at first sight, appears to be the subject of spondyl-arthritis of the vertebrae of the neck. If any attempt be made to draw the head forcibly forwards, the greatest pain is felt in the neck. At the same time, the skin is hot, the cheeks of bluish-red colour, and the pulse strong. But, in very acute cases, the extremities soon become cold, the pulse weak and rapid, and then follow sopor and death. In the less acute cases, the symptoms are less rapid in progress, but still characteristic enough. In those who recover, the sickness ceases; but the headache often continues, with restlessness, etc., even when convalescence is far advanced. Convalescence is slow. In one case, complete deafness—evidently the result of effusion—remained. Another boy of 15 remained unconscious several days during the height of the fever; and there is much doubt whether he will ever fully recover his senses.

DEATH OF EDWARD DANIELL, Esq.

THE profession will hear with profound regret of the decease of one of the foremost members of the Association, Edward Daniell, Esq., late of Newport Pagnell. Mr. Daniell had only a few weeks retired from practice, in the active duties of which he had been engaged for half a century. He had taken a house at Stony Stratford; and had intended, in the quiet retirement of his life, to collect his scattered literary and scientific papers, and republish them in a revised and connected form. Unhappily, this was not to be. Mr. Daniell had been for some time past rather failing. Before he left Newport Pagnell, he had been subject to boils; but had not been confined to the house. In the latter part of May, a large carbuncular boil commenced to form at the back of the neck, and attained so much importance, that on June 4th, Dr. Richardson was sent for in consultation. For some days, it was hoped, although the local mischief was very extensive, that the patient would have sufficient restorative power to recover. In the course of the week, he kept up fairly, and on June 9th the carbuncular swelling was discharging freely from an opening which had been made after producing anæsthesia by cold. A part also looked healthy; but there was an evident decrease of systemic power. On the 13th, the stomach became irritable. From this time, he gradually declined until the 16th, when he died at 10.15 A.M. Mr. Daniell was attended throughout his illness with unremitting care by his two sons, Mr. Alfred Daniell of Kegworth and Mr. Wm. Daniell, and was also visited on several occasions by Dr. Richardson. He was in his seventieth year. Briefly recording his death, and offering, as we are sure we may do, the sympathies of the whole Association to his bereaved family, we reserve for a future number an account of his life and labours from the pen of one of his most intimate professional friends.

DIVISION OF THE CERVIX UTERI. Dr. Marion Sims answers Mr. Spencer Wells's objection in reference to this operation. "Mr. Wells says he has seen 'many women in whom,' after this operation, 'the vaginal portion of the cervix has curled up and almost disappeared, while the remains of the cervical canal or the os internum have become nearly impervious.' I have never seen such a result after any of my operations, and do not know what it means or how to account for it. My only trouble before, is to keep the os externum sufficiently open. I am greatly surprised to find Mr. Wells objecting to the use of the speculum. Does he not use a speculum almost every day, and sometimes very often in the day? If it is indelicate to use a speculum for incising the os, is it less so to resort to it for cauterising the same, or for other operations that demand its use? He seems also to object to my speculum because an assistant is necessary to hold it. It would be far better if all medical men would adopt my plan of having a third person in the room, whether as assistant or not, whenever a vaginal or speculum examination is to be made. It is much more delicate for a lady to be locked up in a room for half an hour with a doctor and a nurse than to be so locked up with a doctor alone!"

Progress of Medical Science.

MEDICINE.

APPLICATION OF MUSTARD IN INSANITY. Dr. S. Newington recommends a new remedial agent in the treatment of insanity and other diseases. It is the application of mustard as an irritant to the surface of the body. Five or six handfuls of mustard may be employed in an ordinary bath; or the mustard may be mixed with linseed meal and applied largely to the abdomen—the object being to produce a desiccative action of blood to the skin. Dr. Newington says that he finds the agent a powerful remedy in mania, inducing sleep where other remedies have failed. His theory of its use is, that the brain is in an unusual state of activity, and consequently there is an unnatural determination of blood to the organ, preventing sleep. By the remedy, blood is driven from the brain, and sleep induced.

HYDATID CYST OF THE LIVER TREATED BY CAUSTIC; INTRACYSTIC HÆMORRHAGE; DEATH. A man, aged 34, was admitted lately into the Hôtel Dieu at Lyons. He was apparently of vigorous constitution; but his health was greatly impaired by a disease of the liver. Four years previously, a tumour had appeared in the right hypochondrium, and now occupied a space bounded by two vertical lines passing, one at the distance of four finger-breadths from the umbilicus and the other through the centre of the ribs; and by two horizontal lines at the level of the xiphoid cartilage and of the right iliac crest. The development of the tumour had been accompanied by severe derangement of the digestive organs, by loss of appetite and of strength, and by icterus. The history and aspect of the case led to the supposition that it was one of hydatid cyst of the liver; and this opinion was confirmed by an exploratory puncture with a trocar. M. Gayet, under whose care the patient was, decided on opening the cyst by caustic, and afterwards washing it with disinfectant and slightly styptic solutions. Accordingly, Vienna paste was applied over an extent of seven *centimètres* parallel to and two finger-breadths below the false ribs; after which Canquoin's paste was applied for nine days successively, until the cyst was opened. Four quarts and a half of yellow liquid escaped, in which no trace of echinococcus could be found. The discharge was arrested, in order to prevent hæmorrhage into the vacuum; but, after the patient had apparently passed a day favourably, he was seized in the evening with rigor, nausea, hiccup, cold sweats of the limbs, and other symptoms of hæmorrhage. On the following day, the patient was in the same state; the abdomen had again become distended; and the finger, when introduced into the cavity, came into contact with a large mass of clots, beyond which was felt a soft floating substance, which might have been taken for intestine, but that it was certain that the peritoneum had not been entered. In order to prevent putrefaction, M. Gayet contrived an apparatus for the continuous irrigation of the sac; but the patient gradually sank, and died four days after the opening of the cyst. On *post mortem* examination, the liver was found to be enlarged, with the cyst occupying its lower surface. The gall-bladder was healthy. In the interior of the cyst, there was found to be a second cyst, having walls of a homogeneous translucent substance; there were no traces of vessels nor of organised structure. It was filled with vegetations, formed of a finely granular substance arranged

in alternately dark and clear bands, like the walls of echinococcus vesicles; but no hooklets could be found. (*Gaz. Méd. de Lyon*, 15 Mai, 1865.)

MUSCULAR CONTRACTION SUCCESSFULLY TREATED BY SUBCUTANEOUS INJECTION OF ATROPINE. Madame B., aged 31, had, at the age of 11, when her mother died, a severe attack of hysteria, which recurred several times. When she was 18 years old, a second attack was followed by a lethargic state which lasted three days. She was believed to be dead, and preparations were being made for her funeral, when she recovered. She was married at the age of 19, and became the mother of three healthy children. Her health seemed to be re-established; when, in November last, she had a hysterical attack (the precise nature of which is not stated) which lasted for twenty-four hours, and was followed by general contraction of the lower limbs. This yielded on the next day; but the left foot remained strongly retracted, presenting the appearance of a well marked varus. The external edge rested on the ground; the sole was very concave; the external malleolus projected, but the internal one could scarcely be felt. This state continued two months, in spite of all treatment; becoming indeed worse, so that the foot appeared subluxated. Dr. Boissarie, the patient's medical attendant, then injected at the point of exit of the sciatic nerve, twelve drops of a solution containing 5 centigrammes of sulphate of atropine in 20 grammes of water (1 part in 400). In half an hour, the patient had nausea, a sense of constriction of the throat, and disturbance of vision; these symptoms continued through the day and a part of the night. The foot, which hitherto no traction had availed to bring into its normal position, could now be moved readily in every direction. The patient was now able to walk; but this was attended with a tendency to the part of the foot, probably from weakness of the antagonistic muscles. As there was still some stiffness in the muscles which had previously been contracted, two injections—one of eight drops and the other of four—of the above-mentioned solution, were made at intervals of three days. They entirely removed all traces of contraction. (*Gaz. des Hôp.*, and *Bull. Génér. de Thé.*, Avril 1865.)

ANATOMY, PHYSIOLOGY, & PATHOLOGY.

HYSTERICAL ANÆSTHESIA AND ATAXIA. M. Lasègue relates and comments on the case of a patient in the Hôpital Necker, a girl who, at the age of 18, was seized with hysteria, and afterwards with catalepsy. The cataleptic attacks recurred every two or three days at uncertain intervals, and lasted, on an average, two or three hours each. The sleep was calm, and difficult to be distinguished from physiological sleep. M. Lasègue applied to the patient electricity, pinching, pricking, and other means of irritation, without producing the least effect. All the muscles appeared to be under the cataleptic influence, except those of the face; the jaws were fixed, but the lips and eyelids resumed their normal position when the hands were removed after separating them. The patient had anæsthesia of the limbs and of part of the body; the face, skull, and a part of the neck retained some sensibility. The anæsthesia was not only cutaneous, but deep-seated; needles could be plunged deeply into the patient without producing the least evidence of pain. M. Lasègue availed himself of the opportunity of investigating the influence of this state on the muscular action, and arrived at the following results. When the patient's eyes were bandaged, she could move the muscles lying under the

parts where sensation remained, but not those lying under the anæsthetic parts of the body. Thus she moved the head, neck, and body; but the limbs were immovable, and, when put into any position, they remained there without producing the least fatigue, as if the patient were in a partially cataleptic state. This phenomenon was observed both in the lower and in the upper limbs; and yet the patient walked without looking at her feet, and with her eyes fixed on the ceiling. When her eyes were shut, she could not raise her hand to the head; but, if she had the fingers applied on a sensitive point of this region, she could, with some hesitation, perform definite movements. With her eyes open, the patient could, even with some expertness, perform the most delicate movements—provided that she never raised her eyes. When her sight was directed towards a distant object, her movements were restrained, but less so than when the eyes were closed. If obliged to look at an object within reach, she could not extend her hand to it, unless she could see her arm; but this became possible if she could distinguish the movements of the arm through her clothes.

M. Lasègue makes a number of interesting observations, and concludes as follows. The sense of muscular activity is more complex than appears at first. It is composed of elements furnished by sight, by touch, and by the slow and gradual education of movements. Each movement in itself represents a succession of phenomena, capable of being minutely analysed, from the time when motion has been determined on to the time when the object has been accomplished; and from this chain, apparently indissoluble, one or more links may be wanting. In hysterical cataleptics, the rigidity of the muscular organism, the disappearance of volition, the intervention of the sight and of touch, are so many elements, diversely modified according to circumstances, which change the results produced. (*Archives Générales de Méd.*, and *Gaz. Méd. de Paris*, 29 Avril 1865.)

CONSAINGUINEOUS MARRIAGES. Dr. A. Mitchell has discussed the question of "the Influence which Consanguinity in the Parentage exercises on the Offspring"; and the following are the conclusions at which he has arrived.

1. Consanguinity in parentage tends to injure the offspring. This injury assumes various forms. It may show itself in diminished viability at birth; in feeble constitutions exposing them to increased risk from the invasion of strumous disease in after-life; in bodily defects and malformations; in deprivation or impairment of the senses, especially those of hearing and sight; and, more frequently than in any other way, in errors and disturbances of the nervous system, as in epilepsy, chorea, paralysis, imbecility, idiocy, and moral and intellectual insanity. Sterility or impaired reproductiveness is another result of consanguinity in marriage, but not one of such frequent occurrence as has been thought.

2. When the children seem to escape, the injury may show itself in the grandchildren; so that there may be given to the offspring by the kinship of their parents a potential defect which may become actual in their children, and thenceforward appear as an hereditary disease.

3. Many isolated cases, and even groups of cases, present themselves in which no injurious result can be detected. This may occur even when all other circumstances are of an unfavourable character.

4. As regards mental disease, unions between blood-relations influence idiocy and imbecility more than they do the acquired forms of insanity, or those which show themselves after childhood.

5. The amount of idiocy in Scotland is to some extent increased by the prevalence of consanguine marriages, but the frequency of these marriages does not appear to be nearly so great as has been generally supposed. (*Edinburgh Medical Journal*, June 1865.)

PATHOLOGY OF HYDROPHOBIA. In a course of lectures on hydrophobia, published by Dr. T. C. Shinkwin from the manuscript notes of the late Dr. T. S. Holland of Cork, the following conclusions are given. 1. No one of the morbid appearances that are stated to have occurred in autopsies made on persons who died of hydrophobia, nor all taken collectively, could produce the symptoms essential to that disease, and that it presents phenomena for which none of these pathological changes can account. 2. Hydrophobia can proceed to a fatal termination without leaving in the dead body any trace of diseased change. 3. All the pathological appearances hitherto recorded must be considered as secondary or accidental lesions, to none of which can be assigned the place of the *proximate cause*, which is still unknown. 4. From a consideration of the sudden, interrupted, intense, and rapidly fatal character of the symptoms, it appears highly probable that as the blood is the most generally diffused and rapidly circulating medium, it is the receiver of and agent through which the nervous system is acted on by the poison and excited by it to produce the symptoms characteristic of hydrophobia. 5. Presuming the correctness of the last conclusion, it follows from it that treatment should be directed to remove the altered condition of the blood, and that attention should in all future autopsies be directed to discover the physical, chemical, and microscopical changes occurring in it and in the nervous system. 6. If it be necessary to give this disease a nosological order, it should be placed among a series of affections that may be included under the general term of toxo-sanguineo-nervous diseases. (*Dublin Medical Press*, May 17th, 1865.)

TUBERCULAR DISEASE IN A MONKEY. At a meeting of the Pathological Society of Dublin, the Rev. Professor Haughton exhibited the body of a large monkey (*Macacus Nemestrinus*), which had died recently in the Zoological Gardens of that city from tubercular disease. The animal was a very large and handsome one of its kind. Dr. Haughton observed that, although it is a common opinion, and is expressed in many works on natural history, that monkeys in confinement are very liable to tubercular disease, he had not found, during over six years' constant dissection of the monkeys who had died in the Gardens, one instance of the kind until the present. Most of the animals had died from scrofula or from pneumonia. The present macaque appeared perfectly healthy until about four weeks before death, when he suddenly lost his appetite, and became worse from day to day. Various foods were tried with him, but no medicine. He died rather abruptly. On making a *post mortem* examination, Dr. Haughton found the whole internal viscera affected with tubercular disease. The lungs, both right and left, but particularly the right, were filled both on the surface and through their substance with milary tubercle. The disease appeared to have attained its most advanced stage in the lungs. There were two or three specks on the surface of the heart, which had exactly the same feel as the milary particles in the lung. The liver contained five lobes, four of which were completely filled with tubercular matter; the fourth lobe was a complete mass of it; the disease in this was more advanced than in the others, and bore the appearance of a cheesy deposit. The spleen was also affected

with the same disease, and from its appearance Dr. Haughton thought the disease even more advanced in this organ than in either the liver or lungs. The mesenteric glands were conglomerated into one large tubercular mass. There was no diarrhoea during the progress of the disease, and exceedingly little cough. The glands of the lumbar region were healthy, but the spinal glands among the back of the thorax were the seat of tubercle. Dr. Haughton also found that the animal had suffered from chronic rheumatic arthritis, which had caused dislocation of both patellæ over the external condyle. The rheumatic arthritis had completely cut away the top of the external condyles of both thighs and the inferior surfaces of the patellæ. From this cause doubtless it was that the animal for some time previous to his death appeared to prefer sitting on his rump to any other attitude, squatting on the callosities of the skin. Some months ago Dr. Haughton dissected a lion which died in the Gardens, and found the animal had suffered from rheumatic arthritis of the left shoulder-joint. The appearance presented by the bone in both cases was identical, and showed that the disease must have originated while the animal was in a state of confinement, the bone having partially rotted away, and not exhibiting the polished ivory surface which it would present were the animal capable of enjoying its natural amount of exercise. (*Dub. Med. Press*, May 10th, 1865.)

RENO-PULMONARY ABSCESS. At a meeting of the Pathological Society of Dublin, Dr. Gordon exhibited a specimen of this rare disease. The subject, aged 24, had been a patient in the Whitworth Hospital. On admission, she was affected with hectic, profuse night-sweats, purulent expectoration, diarrhoea, and emaciation; and passed large quantities of pus in the urine. The physical examination of the chest discovered the existence of an abscess in the right lung. About four days before her death, in addition to the symptoms already enumerated, there was observed a peculiar strong gangrenous fetor, both from her breath and from the expectoration. This symptom continued up to her death, and from the moment of its appearance she began to sink most rapidly. On tracing the progress of the disease from the kidney, the original cause was found to have been the presence of a large calculus in the pelvis of the kidney, in addition to which was another large calculus lying loose in the distended kidney, which was completely filled with purulent matter. The capsule of the kidney was also separated from it, the intervening space being occupied by a very large quantity of purulent greyish matter, mixed with some soft tenacious lymph. This abscess had escaped in some degree from the distended capsule, and so prevented the enormous distension which takes place in many instances. From this the matter passed upwards, displacing the inferior edge of the liver forwards; and, passing up and occupying the posterior surface of the liver, it pressed upwards against the inferior surface of the diaphragm, forming a large pouch, lined with soft lymph, and with the abscess pressing it upwards. The diaphragm, though thin, was not actually perforated. On examining the upper surface of the diaphragm, a state of things was found to exist similar to what was below—viz., a large abscess lay on the wasted upper surface of the diaphragm, corresponding in position to that which lay on the inferior surface. The base of this upper abscess was formed by the diaphragm; the upper part was formed by a large abscess existing in the lung, which, under ordinary circumstances, would have opened in the cavity of the pleura and caused pneumothorax, but in this case was bound down by thick

and strong lymph all around it. If the patient had lived sufficiently long a communication would, no doubt, have been established between the two abscesses. On further examination, two large ulcers were found in the duodenum. Dr. Gordon thought these accidental, and not connected with the renal abscess, which was endeavouring to make its exit by perforation through the duodenum, and which the lung, as far as it could, was assisting on the upper surface. (*Dub. Med. Press*, June 14th, 1865.)

USES OF SUGAR AND LACTIC ACID IN THE ECONOMY. In the April number of the *American Journal of Medical Sciences*, is a paper on this subject by Professor S. Jackson. He says that the facts marked out by M. Claude Bernard prove that, in the first stage of organic or nutritive actions, in animal as in vegetable life, glucose (grape-sugar) is an indispensable agent in the formation of plastic matter and organic forms. Milk, which has sugar as a large constituent, is the food of mammalia. At a later period of life, the supply of sugar is obtained to a large extent from fruits, etc., and by the conversion of the starchy elements of food into saccharine matter. Nature also has endowed the liver with a glucogenic function, by which the organism is supplied with glucose. Although constantly formed, it never accumulates in health, so it must either be transformed or destroyed. In certain conditions neither is done, and the blood and all eliminations from it are found charged with glucose, as in diabetes mellitus. As a general rule the change of amyloid matter and cane-sugar occurs in the alimentary canal, usually the stomach in most animals, although in dogs it occurs further along in the duodenum, by the pancreatic fluid. Absorption of dextrin and glucose unchanged also may take place, and the transformation may occur in the blood or through the agency of some organ. Glucose cannot remain long as such under the influence of oxygen, heat and moisture, but is transferred into lactic acid. This product appears to be the final object of the vast provision of starch and sugar. Professor Jackson states in conclusion, that Drs. W. F. Atlee and J. H. Packard have recently treated gangrenous wounds successfully with sugar. The active principle is not the sugar as supposed, but the lactic acid into which the saccharine matter has "been converted, by contact with animal substances in a state of decomposition" (Liebig.) He suggests that lactic acid should be tried direct, by the use of sour milk. The wound should be thoroughly washed with milk, and cleansed of putrid matter, and then bound with lint, kept saturated with acid milk. His explanation is supported by the well known fact that the gastric juice, which is an antiseptic, always contains lactic acid, and thereby arrests putrefaction. (*Philadelphia Medical and Surgical Reporter*, May 13th, 1865.)

MIDWIFERY AND DISEASES OF WOMEN.

RELAXATION OF THE PELVIC ARTICULATIONS AFTER LABOUR. Difficulty of locomotion coming on after parturition has been several times noticed (especially by French writers). It is liable to lead to the idea that the patient is suffering from spinal or uterine disease. But when it occurs in women who have been recently delivered, the practitioner should bear in mind the possibility of its arising from relaxation of the articulations of the pelvis. By palpation and pressure over the sacro-iliac synchondroses and over the pubic symphysis, pain is produced; and the point of the finger can often, in the latter situation, be introduced between the bones. M. Trouseau, in a clinical lecture on the subject, recognises

the value of rest, topical astringents, and tonics; but he urges especially the necessity of applying a firm bandage so as to embrace not only the bones of the pelvis, but the trochanters of the thigh-bones. (*L'Union Méd.*; and *Bulletin Génér. de Thérap.*, Avril 30, 1865.)

Association Intelligence.

MEDICAL PROVIDENT SOCIETY.

CONTRIBUTIONS TO THE AUXILIARY FUND.

SIR,—I have much pleasure in stating that I have this day received from T. Taylor Griffith, Esq., of Wrexham, a cheque for Seventy Pounds, being the amount of donations collected by him for the Auxiliary Fund of the above named Society. Of this sum, £50, collected principally from members of the North Wales Branch, are intended as a response to the generous invitation made some time ago by Mr. Carden of Worcester; who has promised to give £50 (in addition to his former donation), provided that ten others will also each contribute a like sum.

The subjoined is a copy of the list sent me by Mr. Griffith.

	£	s.	d.
A Friend (Surgeon)	10	0	0
Dr. Hughes (Mold)	2	2	0
Dr. Roberts (St. Asaph)	2	2	0
Dr. Edward Williams (Wrexham)	2	2	0
John Dickenson, Esq., Surgeon (Wrexham)	2	2	0
A. E. Turnour, Esq., Surgeon (Denbigh)	1	1	0
Dr. Burton (Ruabon)	1	1	0
Dr. Davies (Wrexham)	1	1	0
Dr. Davies (Holywell)	1	1	0
T. F. Edwards, Esq., Surgeon (Denbigh)	1	1	0
J. Edmunds, Esq., Surgeon (Chirk)	1	1	0
Frederick Heaton, Esq., Surgeon (Wrexham)	1	1	0
T. Eytton Jones, Esq., Surgeon (Wrexham)	1	1	0
T. Evans Jones, Esq., Surgeon (Llanasa)	1	1	0
E. Turner Jones, Esq., Surgeon (Denbigh)	1	1	0
D. Kent Jones, Esq., Surgeon (Beaumaris)	1	1	0
Dr. Jenkins (Ruthin)	1	1	0
Dr. Jones (Ruabon)	1	1	0
L. L. Lodge, Esq., Surgeon (St. Asaph)	1	1	0
R. C. Roberts, Esq., Surgeon (Ruabon)	1	1	0
F. Theed, Esq., Surgeon (Rhyll)	1	1	0
Dr. Harvey Williams (Rhyll)	1	1	0
Dr. Williams (Mold)	1	1	0
Thos. G. Prytherch, Esq., Surgeon (Wrexham) ..	1	1	0
J. E. Eytton, Esq., Surgeon (Overton)	1	1	0
Wm. Bennett, Esq. (Morecambe)	1	1	0
T. T. Griffith, Esq., Surgeon (Wrexham)	8	10	0
	50	0	0
Miss Bennion (Wrexham Vechan), by Dr. Edward Williams	10	0	0
A Friend, by T. T. Griffith, Esq.	10	0	0
	70	0	0

In addition to this sum, and to £668:3:0 already announced in the JOURNAL, the following contributions to the Auxiliary Fund have been made since the publication of the last list.

	£	s.	d.
John Clay, Esq. (Birmingham)	10	10	0
Dr. J. G. Davey (Northwoods, Bristol)	5	5	0
Dr. Desmond (Liverpool), additional	7	7	0
Dr. Fitch (Chaddesley Corbet)	1	1	0
C. Hooper, Esq. (Aylesbury)	5	5	0
Dr. S. W. J. Merriman (London)	10	10	0
Dr. B. W. Richardson (London)	21	0	0

The Auxiliary Fund, therefore, now amounts to nearly £800: the greater part of which is placed at interest in a London bank.

I am, etc.,
ALEXANDER HENRY,
Secretary to the Medical Provident Society.

15, George Street, Portman Square, W., 20th June, 1865.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFRESON, M.D. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S.Ed., Professor of Clinical Surgery in the University of Edinburgh.

Gentlemen intending to read papers, cases, or any other communications, are requested to give notice of the same to the General Secretary, at their earliest convenience.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
CAMBRIDGE AND HUNTINGDON. [Annual.]	Ely.	Tuesday, June 27th, 11 A.M.
MIDLAND. [Annual.]	Town Library, Town Hall, Leicester.	Wednesday, June 28th, 2 P.M.
NORTHERN. [Annual.]	Library, Newcastle-upon-Tyne Infirmary.	Wed., June 28, 10.30 A.M.
METROPOL. COUNTIES. [Annual.]	Crystal Palace, Sydenham.	Tuesday, July 4th, 3 P.M.
NORTH WALES. [Annual.]	Royal Hotel, Rhyl.	Tuesday, July 4, 12 noon.
WEST SOMERSET. [Annual.]	Clarke's Castle Hotel, Taunton.	Tuesday, July 4, 2.30 P.M.
EAST ANGLIAN. [Annual.]	Council Chamber, Town Hall, Ipswich.	Friday, July 14th, 2 P.M.

CAMBRIDGE AND HUNTINGDON BRANCH.

THE Annual Meeting of the Cambridge and Huntingdon Branch will be held at Ely, on Tuesday, June 27th, at 11 A.M.; J. MURIEL, Esq., President, in the Chair.

Gentlemen intending to read papers or cases are requested to forward the titles of the same to the Honorary Secretary, without delay.

P. W. LATHAM, M.D., *Hon. Secretary*.

15, Sidney Street, Cambridge, June 1865.

NORTHERN BRANCH.

THE First Annual Meeting of the Northern Branch will be held in the Library of the Newcastle-upon-Tyne Infirmary, on Wednesday, June 28th, at 10.30 A.M.; D. B. WHITE, M.D., President.

Gentlemen intending to read papers and cases, are requested to forward the titles of the same to the Secretary, without delay.

G. H. PHILLIPSON, M.B., *Hon. Secretary*.

Newcastle-upon-Tyne, June 1865.

MIDLAND BRANCH.

THE Annual Meeting of the Midland Branch will be held on Wednesday, June 28th, at 2 P.M., in the Town Library, Town Hall, Leicester; JOHN BARCLAY, M.D., President.

Gentlemen intending to read papers or cases, are requested to forward the titles of the same, without delay, to the Honorary Secretary.

JOHN SLOANE, *Hon. Secretary*.

Welford Place, Leicester, June 1865.

METROPOLITAN COUNTIES BRANCH.

THE Thirteenth Annual Meeting of the Metropolitan Counties Branch will be held at the Crystal Palace, Sydenham, on Tuesday, July 4th, at 3 P.M.

President for 1864-65 CHAS. F. J. LORD, Esq.

President-elect for 1865-66... E. H. SIEVEKING, M.D.

After the meeting, the members and their friends will dine together; E. H. SIEVEKING, M.D., in the Chair. Dinner on the table at 5.30 P.M. precisely.

A. P. STEWART, M.D.

ALEXANDER HENRY, M.D. } *Hon. Secs.*

74, Grosvenor Street, June 1865.

WEST SOMERSET BRANCH.

THE Annual Meeting of the West Somerset Branch will be held at Clarke's Castle Hotel, Taunton, on Tuesday, July 4th, at 2.30 P.M.; HUGH NORRIS, Esq., President.

Gentlemen are requested to give notice to the Secretary of cases or papers they may wish to communicate.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, June 1865.

EAST ANGLIAN BRANCH.

THE Annual Meeting of the East Anglian Branch will be held in the Council Chamber, Town Hall, Ipswich, on Friday, July 14th, at 2 P.M.; A. H. BARTLET, M.D., President.

Dinner at 5 P.M.

Members are requested to forward to Dr. Chevallier the titles of any papers or cases they may wish to communicate, on or before June 30th.

B. CHEVALLIER, M.D., *Hon. Secretary*.

Ipswich, June 14th, 1865.

DRUNKARD CURING. It is said that the managers of the New York Inebriate Asylum have concluded, after trial, that they cannot cure a drunkard in less than a year.

THE YOUNG MEDICAL STUDENT. There was much which tended to damp my ardour in the beginning. A very few days were sufficient to overcome the disgust occasioned by my first entry into the dissecting-room; but the study of bones and muscles and bloodvessels was far from being attractive in the first instance. In the theatre and the dissecting-room, I felt, though with numbers around me, like a solitary person. Between myself and the great majority of the students there was nothing in common. In a medical school, indeed, there is a great mixture of persons. There is always a certain number of well-educated young men. But these are a minority. The effect of the absurd system of apprenticeship to an apothecary—which custom formerly, and since that an Act of Parliament, has imposed on what are called practitioners—is that the great mass of students are sadly deficient in this respect. There were only two among them with whom I had much acquaintance: one of them a young physician of the name of Crawford, a nephew of Crawford who wrote on animal heat, and who died not very long afterwards; and the other was Lawrence, who has since acquired so large and well-deserved a reputation. The latter was, even then, a remarkable person. I never knew any one who had a greater capacity for learning than he had, nor more industry, nor who at the same age had a greater amount of information, not merely on matters relating to his future profession, but on a great variety of other subjects. (*Sir B. Brodie's Autobiography.*)

Medical News.

UNIVERSITY OF CAMBRIDGE. Degree of M.D. conferred at a Congregation held on June 17.

Bagshawe, Frederic, St. John's College
 Cheadle, Walter Butler, Caius College
 Jeaffreson, Samuel John, Pembroke College

UNIVERSITY OF DURHAM. Examination for a Licence in Medicine.

Redwood, T. H., B.A., Bishop Hatfield's Hall

First Examination for License in Medicine and Mastership in Surgery.

Hope, John, Newcastle College
 Newcombe, Frederick William, Newcastle College
 Newton, R. C., Newcastle College

The Barry Scholarship has been awarded to John Caparn Cammack, Bishop Hatfield's Hall; and the Newby Scholarship to James Lister, University College.

APOTHECARIES' HALL. On June 15th, 1865, the following Licentiates were admitted:—

Arnulstead, John William, Leeds
 Haward, Frederick Robertson, Halesworth, Suffolk
 Jones, Alfred, Cardigan
 Mackinnon, Henry W. Alexander, Portugal Street, Lincoln's Inn

At the same Court, the following passed the first examination:—

Dalton, Benjamin Neale, Guy's Hospital
 Elliott, Arthur Bowes, Guy's Hospital
 Lamb, Barnabas Walter, St. Bartholomew's Hospital
 Square, William, St. Bartholomew's Hospital

APPOINTMENTS.

SUTTON, H. G., M.D., has been appointed Assistant-Physician to the Hospital for Diseases of the Chest, Victoria Park.

ROYAL NAVY.

AYRE, William G. J., Esq., Surgeon (additional), to the *Edgar*.
 BRAKE, William, Esq., Surgeon, to the *President*.
 BRICE, Frederick, Esq., Surgeon (additional), to the *Terror*, for Bermuda Hospital.
 SPENCILL, Charles, Esq., Surgeon, to the *Liffey*.
 WHITNEY, James L., Esq., Assistant-Surgeon, to the *Impregnable*.
 WRIGHT, F. L. W., Esq., Assistant-Surgeon, to the *Liverpool*.

MILITIA.

FOOTITT, W. F., Esq., to be Assistant-Surgeon Royal Sherwood Foresters or Nottinghamshire Militia.
 WRIGHT, H., Esq., to be Assistant-Surgeon East and North York Artillery Militia.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.=Rifle Volunteers):—

JACKSON, H., Esq., to be Surgeon 1st Administrative Brigade Argyllshire A.V.

BIRTH.

BARBER. On June 16th, at Ulverstone, the wife of Henry Barber, M.D., of a son.

DEATHS.

*BOND, Charles, M.D., at Lutterworth, aged 42, on June 11.
 *DANIELL, Edward, Esq., late of Newport Pagnell, at Stony Stratford, aged 69, on June 16.
 O'CONNOR. On June 12th, at March, Cambridgeshire, aged 14, Ellen, daughter of T. O'Connor, Esq.
 *WILSON, William Murray, Esq., at Horsforth, near Leeds, aged 70, on June 19.

UNIVERSITY OF OXFORD. At a congregation held on Wednesday last, the honorary degree of D.C.L. was conferred on Robert Christison, M.D., of Edinburgh, and William Stokes, M.D., of Dublin.

UNIVERSITY COLLEGE HOSPITAL. The anniversary dinner was held on Wednesday last at Willis's Rooms; Lord Belper in the chair. About 120 gentlemen were present.

CEREBRO-SPINAL MENINGITIS. A few cases, in a mild form, of cerebro-spinal meningitis, have been observed at Vienna.

Dogs. On the motion of Mr. D. Damer, returns have been ordered of all persons bitten by dogs and conveyed to hospitals since the 1st of January, 1865, within the limits of the metropolis.

DR. GRAILY HEWITT is a candidate for the Professorship of Midwifery in University College. His success as a Lecturer at St. Mary's Hospital, and his well known literary labours in midwifery and the diseases of women, give him the highest claims to the consideration of the elective body of the College.

THE COST OF ALCOHOL. Professor Frankland, in a lecture delivered at the Royal Institution, stated that "the cost of a gallon of pure alcohol, as contained in the following wines and spirits, was, in brandy, 49s.; rum, 28s.; sherry, 85s.; port, 119s.; claret, 142s.; champagne, 172s.; in ale and stout only 15s."

IRISH LUNATICS. By a return issued a few days ago, it appears that in the year 1864 there were committed to county gaols in Ireland 460 dangerous male lunatics, and 292 females—752 in all. The number of insane persons confined in distinct asylums in the same year was 5914; while the total number of persons which such asylums are capable of accommodating is only 4959.

MR. WILLIAM WEBBER, well known as the defendant in the case of Wells *versus* Webber for libel, tried a few years ago, and for his allegations in regard to the insalubrity of Tunbridge Wells, has obtained a verdict for £50 against a printer of that place for not affixing his name to certain verses published in ridicule of Mr. Webber.

DR. PRITCHARD'S TRIAL. The trial of Dr. Pritchard is to come off on Monday, July 3rd. The number of witnesses for the prosecution is about 87. The indictment charges the prisoner with having poisoned Mrs. Pritchard and Mrs. Taylor with antimony, aconite, and opium. The Lord Advocate is to conduct the prosecution, and Mr. Rutherford Clark and Mr. Watson have been engaged for the defence.

SURGERY v. MEDICINE. After an experience of fifty years, I am confirmed in the opinion that the pursuit of what is called pure surgery, such as it is in large cities, in connection with a hospital and a medical school, is more replete with interest, and, on the whole, more satisfactory, than any of the other branches into which the *ars medendi* is divided. (Sir B. Brodie's *Autobiography*.)

DEATH FROM CHLOROFORM. The *Liverpool Mercury* gives the inquest held on a child about two years, which had died from chloroform administered for the removal of a finger. About thirty drops were placed on lint over the child's mouth for about two minutes. The child died in about five minutes after the commencement of the inhalation. The jury's verdict was: Died from the effects of chloroform by misadventure. No blame was attached to either Dr. Sinclair or Mr. Prytherch.

DISTRICT LUNATIC ASYLUMS (IRELAND.) In the House of Commons on the 16th instant, Mr. Blake asked the Chief Secretary for Ireland whether he had any objection to state if the Irish government, before appointing persons to the office of resident physician to the district lunatic asylums, required satisfactory proof that they had acquired a practical knowledge of the treatment of insanity; and, if candidates were examined as to their fitness to be entrusted with the care and treatment of the insane by the inspectors of asylums, and a report made thereon to the Lord Lieutenant. Sir R. Peel answered in the affirmative.

THE RAILWAY ACCIDENT AT REDNAL. Thirty patients injured by the railway accident at Rednal were admitted into the Shrewsbury Infirmary under the care of Mr. Wood. Nine persons were killed at the scene of the accident, and three died in the Infirmary. It is a somewhat singular fact that no (cutting) surgical operation was required in any of the hospital cases. Broken legs, ribs, clavicles, arms, and scapulas, and injury to the abdominal viscera, etc., were the injuries there treated.

ROYAL COLLEGE OF SURGEONS OF IRELAND. The annual meeting of the College was held on Monday, the 5th instant, when the Officers and Council of the College for the ensuing year were elected as follows. *President*—Samuel G. Wilmot. *Vice-President*—Richard G. H. Butcher. *Secretary*—William Colles. *Council*—Arthur Jacob, William Hargrave, Robert Adams, William Colles, James Barker, Hans Irvine, Robert Pentland, Thomas L. Mackesy, Awly P. Baron, Peter Shannon, Rawdon Macnamara, Hamilton Labatt, Benjamin McDowell, Edward Ledwich, William Jameson, Alexander Carte, James H. Wharton, George W. Hatchell, Albert J. Walsh.

LUNACY IN SCOTLAND. The seventh annual report of the Commissioners on Lunacy for Scotland has just been issued. The number of insane persons in Scotland on January 1st, 1864, of whom the commissioners had official cognisance, was 6,391. Of this total 1,039 were supported by private means, 5,320 by parochial rates, and 32 were criminal lunatics in the Central Prison at Perth. The statistics of the seven years ending January 1st, 1864, show on the whole much steadiness in the extent and distribution of lunacy, with latterly some tendency towards diminution in most counties. On comparing the mortality of private and pauper patients, the commissioners find the ratio to be nearly alike on both sides.

ABERNETHY'S LECTURES. He was an admirable teacher. He kept up our attention so that it never flagged, and that what he told us could not be forgotten. He did not tell us so much as some other lecturers; but what he did, he told us well. His lectures were full of original thought, of luminous and almost poetical illustrations, the tedious details of descriptive anatomy being occasionally relieved by appropriate and amusing anecdotes, which, though they had been repeated over and over again, as one course succeeded another, were very agreeable to us new comers. Like most of his pupils, I was led to look up to him as a being of a superior order. (*Sir B. Brodie's Autobiography.*)

POLLUTION OF RIVERS. Instructions have been issued from the Home Office to the commissioners appointed to inquire into the pollution of rivers, directing them to take selected river basins, illustrating different classes of employment and population, with a view to ascertain whether a measure absolutely prohibiting the discharge of the refuse of mines and manufactories into rivers, or absolutely compelling town authorities to carry town sewage on to the lands, might not be remedying one evil at the cost of an evil still more serious in the shape of injury to health and damage to manufactures. The Secretary of State suggests that the following river basins might be taken:—1. The Thames Valley, both as an example of an agricultural river basin, with many navigation works, such as locks and weirs, and mills affecting the flow of water, and many towns and some manufactories discharging their sewage and refuse into the stream from which is mainly derived the water supply of the metropolis; 2. The Mersey Valley, including its feeders, particularly the Irwell, as an example of the river basin most extensively polluted by all forms of manufacturing refuse,

particularly that arising from the cotton manufacture and processes connected therewith; 3. The Aire and Calder Basin, as an additional example of the same class, particularly in connexion with the woollen and iron manufactories; 4. The Severn Basin, for the same reason, but in particular connexion with the great seats of the iron trade; 5. The Taff Valley, in connexion with mining and industry applied to metals; and 6. A river basin comprising a mining district in Cornwall.

POLLUTION OF RIVERS. The Queen has appointed R. Rawlinson, Esq., J. T. Harrison, Esq., and J. T. Way, Esq., to be her Majesty's Commissioners for the purpose of inquiring how far the present use of rivers or running waters in England for the purpose of carrying off the sewage of towns and populous places, and the refuse arising from industrial processes and manufactures, can be prevented without risk to the public health or serious injury to such processes and manufactures; and how far such sewage and refuse can be utilised or got rid of otherwise than by discharge into rivers or running waters, or rendered harmless before reaching them; and also for the purpose of inquiring into the effect on the drainage of lands and inhabited places, of obstructions to the natural flow of rivers or streams caused by mills, weirs, locks, and other navigation works, and into the best means of remedying any evils thence arising.

ENGAGEMENT OF DR. SUTHERLAND. In the House of Commons, on Monday last, Sir S. Northcote asked the Under-Secretary of State for War in what capacity Dr. Sutherland was employed by the War Department; what pay and allowances he received; whether he was paid by salary or by day pay when actually employed, and, if by day pay, for how many days in the year he was employed on an average—from what vote of the Estimates the payment was made; whether the arrangement had received the approval of the Treasury; and whether there would be any objection to lay upon the table of the House a copy of the terms of his original appointment, and of any correspondence between the War Office and the Treasury on the subject. The Marquis of Hartington said that, at the conclusion of the Crimean war, a Royal Commission was appointed to inquire into the sanitary state of the army. Several subcommittees were subsequently appointed. Dr. Sutherland, who had been a member of the Royal Commission, was appointed to serve on four of these subcommittees; and he still continued to serve on the most important of them, the Army Sanitary Committee. The duties of that committee were to consider and report upon all questions relating to sanitary improvements in existing barracks and hospitals, and the most healthy form of construction for new buildings. Dr. Sutherland's great experience and knowledge enabled him to render services upon the committee more valuable probably than those of any other gentleman who could be found. The rate of remuneration was fixed by General Peel at £3:3 per day; and afterwards, upon the recommendation of Mr. Herbert, then President of the Royal Commission, it was continued at the same rate so long as he was completely occupied upon these duties. Dr. Sutherland's time had since been entirely occupied on the details of the business of the Sanitary Committee, and he therefore continued to receive the above rate of remuneration. His salary was charged to the sanitary vote of the Army Estimates. There would be no objection to lay upon the table all the correspondence between the War Office and the Treasury on the subject. The Marquis of Hartington was unable to say whether there was no officer of the army who was qualified to discharge the duties

performed by Dr. Sutherland. It was the opinion of the present Secretary of State, and it had been the opinion of two or three of his predecessors, that these duties were better performed by Dr. Sutherland than they could be by any other person.

CASE OF SUSPECTED SLOW POISONING BY ZINC AND IRON. Mr. Herapath, sen., of the Bristol Medical School says in the *Chemical News*, that at Malmsbury on May 20th an inquest was held on Ann Lait, wife of a horse doctor. Dr. Salter stated in evidence that he had attended Mrs. Lait from April 12th for uterine hæmorrhage and vomiting; the former rapidly ceased, but the latter continued till two days before her death on May 6th. She complained of burning heat of the stomach, fauces, and gullet, coppery taste in the mouth, great thirst and nausea after eating and drinking, followed by vomiting after from half an hour to an hour. The husband had entirely waited upon and fed her. Dr. Salter continued to attend her till the 23rd, on which day he called, and found her coming down stairs; she vomited in his presence; this he secured in a bottle, and subsequently Mr. Herapath received it. He had been struck with her peculiar symptoms, and on calling on the 24th, he saw the husband and wife together, and then said to both that he thought it his duty to tell her "that her symptoms were those of poison, not of disease, advised her to leave home, telling her that if she did she would get well; but if she remained at home she would die, and that he should refuse a certificate in case of her death." They neither of them expressed any concern. On the 29th he gave Lait for her three powders containing oxalate of cerium; on May 5th he called and heard she was sleeping; on the 7th a message was left at his surgery to say she was dead, and in the evening Lait called, and said "he had called in Dr. Jeston, who had seen her on the Tuesday and Thursday before her death." Dr. Salter and Dr. Jeston both refused a certificate. An inquest was held, and a *post mortem* examination followed. On receiving the matters Mr. Herapath found the stomach considerably inflamed in the cardiac portion, and the surface in a strange blistered state; there was not much inflammation of the intestines. In the vomit he found traces of sulphates of zinc and iron, also in the contents of the lower intestines; but in the remains of food in the stomach and duodenum he found only sulphate of iron. These salts, particularly that of zinc, would produce the effects described, but if used as a means of slow poisoning they would, as far as he knows, constitute the first case in which they had been resorted to for the purpose.

THE LATE DR. VALENTINE MOTT. The following account of the funeral of this distinguished American surgeon is abridged from the *Philadelphia Medical and Surgical Reporter* of May 6th. The funeral took place on Sunday, April 30th. The church building in which the funeral services were held, was unable to contain those whose sympathies and feelings induced them to attend. The altar was profusely decorated by crosses, crowns, anchors, wreaths, and massive baskets of flowers, contributed by relatives and admirers of the deceased. One of the baskets bore the letters V. M., in white flowers on a blue ground; another, the word "*Resurgam*"; while, above all, hung a rich wreath surrounding an embroidered cross, with the words, "Christ, our Passover", in illuminated letters across its face. In front of the altar, and beside the pulpit, stood, the pedestal for the coffin, richly draped in sombre black velvet, with floral crosses ornamenting the face of the pall. The font was also filled with flowers, the whole surmounted by a standing cross of japonicas. The reading desk and pulpit were likewise decorated by wreaths. The

mourning drapery for the late President Lincoln, with which the church was hung, still remained. Immediately following the coffin, as it was borne into the church, were the pall-bearers, the members of the Faculty, of the Academy of Medicine, and of the University in Fourteenth Street. Among the gentlemen composing the *cortège*, were nearly all the leading members of the profession in which the deceased held so high a position while living. The pall-bearers were as follows:—Lieut.-Gen. Winfield Scott; G. Bancroft, Esq.; Dr. Martyn Paine; Dr. I. Wood; G. Opdyke, Esq.; Rev. Dr. J. M. Matthews; G. Bibby, Esq.; Dr. W. H. Draper; Dr. A. C. Post; A. T. Stewart, Esq.; Dr. G. T. Elliott; Mr. Routh. Attendant upon the remains were the physicians who were with Dr. Mott during his last illness. Upon the lid of the coffin was a solid silver plate, with the following inscription. "Valentine Mott, M.D., Emeritus of Surgery. Born August 25th, 1785; died April 26th, 1865."

TESTIMONIAL TO DR. ALDIS. At a meeting recently held by medical men and others, it was resolved—"That a testimonial be presented to Dr. Aldis in acknowledgment of the successful efforts which he has made in sanitary progress during a period of twenty-one years, and for the untiring energy with which he has fulfilled the duties of Medical Officer of Health to the parish of St. George, Hanover Square, for more than nine years." In 1844 the Report of the Health of Towns Commission contained some important evidence of Dr. Aldis. He subsequently joined the Health of Towns Association, the Metropolitan Sanitary Association, and assisted in establishing the City and Liberty of Westminster Sanitary Association in 1847, of which he was chairman of the committee during two years, the Earl of Shaftesbury being president. He also gave evidence before the Metropolitan Sanitary Commission when the outbreak of fever occurred at Westminster School and cloisters. During this period sanitary reformers met with much opposition, were thought to be visionaries, and treated with a good deal of contempt; but they devoted much time and money to the object in which they were engaged, and became the pioneers of that sanitary legislation which has produced immense benefit to the labouring population. Among them Dr. Aldis has been an earnest worker; he was always one of that body of unrequited labourers—the dispensary physicians; he has delivered lectures to the working classes on sanitary subjects; in fact, long before he obtained the moderate emoluments of office, his time, purse, and brains were at the service of the poor and of those fellow labourers who desired evidence or information to strengthen their cause. Therefore, we heartily wish success to the "Aldis Testimonial Fund," which the following gentlemen, with others, have already consented to promote—namely, Viscount Walden, Drs. David Davies, Druitt, Ince, S. Day Goss, W. H. Jones, O'Flaherty, W. Pearce, Yearsley, Synnot, Way, Walte, and Webb, the Rev. Messrs. K. B. Foster, J. Cooper, and Lusignan, Messrs. J. R. Lane, J. Teevan, C. A. Elliott, F. Hatchard, and J. Randolph.

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH. At a meeting held on Saturday evening, May 27th, Dr. Druitt, President, in the chair, Dr. Clouston, of Carlisle, read a paper upon The Production of Dysentery by Sewage Irrigation. It consisted in an account of an outbreak of dysentery in the Cumberland and Westmoreland Lunatic Asylum, which was caused by the effluvia from a field irrigated by sewage. The land which was irrigated by the undiluted sewage was a stiff clay, and although the irrigation was practised during the three years

1862-4, it was not until February 1864, that the first case of dysentery occurred. In April three cases of typhoid occurred in an adjoining cottage, but none in the asylum. The dysentery continued until August, when the irrigation being stopped and the sewage diverted from the field, the disease ceased to appear among the inmates of the asylum. Dr. Clouston traced very completely the accordance of the several attacks with such meteorological conditions as were calculated to promote the arrival of the effluvia at the asylum wards. One of the most interesting portions of his paper was that in which he described the pathology of the disease. Altogether there were 31 cases of dysentery, of which 20 were fatal. *Post mortem* examinations were made in 16 of these. The most remarkable feature was the implication of the lower end of the ileum in the inflammation, Peyer's patches, however, being invariably free from disease. He stated that this unusual occurrence was observed also during the dysentery which attacked the British troops during the Walcheren expedition, and also during an epidemic of dysentery at Prague described by Dr. Finger. The following is the summary with which Dr. Clouston concluded his paper. 1. An epidemic of dysentery of a very fatal character occurred in the Cumberland and Westmoreland Asylum in the years 1864-5. 2. All the positive evidence that can usually be produced to determine the cause of any disease can be produced to connect this epidemic of dysentery with exhalations from a field irrigated by sewage as effect and cause. Ample negative evidence can be produced to show that no other probable cause of such an epidemic was in operation. 3. The old paralysed and diseased patients were chiefly attacked, but it was not confined to these. 4. The majority of the patients attacked were inmates of the wards on the ground floor of the asylum, showing that the sewage effluvia is most concentrated near the ground. Little or no wind and a high barometric pressure would seem to be the most favourable conditions for the injurious effects of the poison to manifest themselves. 5. It would seem to be unsafe to apply sewage in any form to land with a stiff clay subsoil within 350 yards of human habitations. 6. Diarrhœa in its ordinary form may also be caused by sewage exhalations. 7. There are strong reasons for believing that the sewage effluvia which caused dysentery and diarrhœa in some persons caused typhoid fever in others. 8. The sewage poison had a period of incubation in most cases before the dysentery appeared; the length of the period was probably from three to five days. 9. The dysentery was of a very fatal character, and the ipecacuanha treatment so successful in tropical dysentery was not so in this epidemic. 10. The two morbid appearances most characteristic of this epidemic were, 1, a soft membranous deposit on the mucous membrane of the intestines; and, 2, the diseased condition of the lower part of the small as well as the large intestines in all the cases. 11. The poison which caused the dysentery seemed to occupy an intermediate position between the poison which causes the continued fevers and that which produces ague and its concomitants.

IRISH MEDICAL ASSOCIATION. The annual meeting of this association was held on Monday, June 5, in the College of Surgeons, Dublin. Dr. Mackesy, the chairman, in an eloquent address, referred to the present social position of the profession in Ireland. At the last meeting he said they had reason to believe that superannuation would be granted to the poor-law medical officers of Ireland; but they had been disappointed. He, however, did not despond, for the justice of the claims of the poor-law medical officers must be recognised. The attorneys, by acting in

union, had sixty-two Irish members to vote in favour of relieving them from a tax. The medical profession had only eleven members to vote in favour of an act of justice and mercy to the broken-down and worn-out members of their profession. How was that? It proceeded from want of union. The medical officers of lunatic asylums, jails, and all other public institutions, had fixed regular salaries, but the poor-law medical officer was subject to being told by his board, that if he continued to be so expensive in the treatment of his patients a resolution would be moved for a reduction of his salary. He (Dr. Mackesy) trusted an amended Medical Charities Act would be introduced which should secure a minimum salary of £100 *per annum* to dispensary surgeons. He hoped that those medical men in Dublin holding high positions who were anxious for educated men to enter the profession, and had not as yet favoured their provincial brethren with their support towards obtaining this most desirable object, would see the advantage of their giving assistance. Unless the poor-law medical officers came forward themselves they must be satisfied to remain as they are, or possibly to sink lower in the social scale. Dr. Mackesy then spoke of the Medical Council. He said: "The time has now arrived for the medical profession generally to speak out, and to record their convictions that the General Council of Medical Education has signally failed in its duty to the public and the profession in not exercising the power entrusted to them; in not laying down a proper standard of preliminary education for candidates about to enter on the study of medicine and surgery; and in not enforcing uniformity and efficiency of examination in the granting of the diplomas by the licensing medical bodies of the United Kingdom. From such omissions on the part of the Medical Council the public are suffering, and the medical profession rapidly deteriorating. The proof of this cannot be more forcibly brought before you than by the result of the examination of candidates during the year 1864 for commissions in the medical departments of the army and navy." Dr. Mackesy read a letter addressed by him to Sir J. Gibson on the subject of the examination of candidates for the army, to which the Director-General replied "that, so far from being third-rate men, the majority of the successful competitors are above the average of those who pass through the schools, as is proved by the fact, that although all must have legal qualifications to practise both medicine and surgery, one-third of those who competed at the last examination failed to obtain the minimum number of marks required to qualify them for admission into the service. Dr. Mackesy next remarked on the breach of faith towards army medical officers relative to the Warrant of 1858, and concluded by referring to the advances made in sanitary science.—The following resolutions were subsequently passed at the same meeting. 1. "That we persevere in our efforts to procure a retiring allowance or a compensation for Poor-law and dispensary medical officers when incapacitated by old age or loss of health in the performance of their duties as public servants." 2. "That the approaching general election will afford the members of our profession an opportunity of bringing under the notice of the several candidates for their support the claims of a profession which hitherto has had but little attention given to it in the British Parliament; and that we urge our brethren not to lose the opportunity of urging said claims in as forcible a manner as possible under the consideration of all parties who aspire to represent them in the House of Commons." 3. "That we value the expressed opinion of the Poor-law Commissioners, who deem less than a hundred a year insufficient payment

for the dispensary medical officers; and that we exercise every legitimate influence to ensure this sum as the minimum." 4. "That it is much to be desired that some fixed principle on the part of the army and navy medical department as to the rank and pay of medical officers be adopted, so as to ensure the best qualified men for appointments in Her Majesty's service." 5. "That the present arrangements for remuneration of members of the medical profession for attending as witnesses in courts of justice, at petty and quarter sessions, are in an unsatisfactory state, and require the earnest and immediate attention of the authorities." 6. "That five guineas be fixed as the minimum charge for the coroner to pay a medical man for performing so dangerous and disagreeable a duty as a *post mortem* examination." 7. "That the Coroners' Bill now brought before the House of Commons be referred to the Council of the Association, in order that such amendments may be adopted as may meet the general wishes of the public and the profession."

OPERATION DAYS AT THE HOSPITALS.

MONDAY......Metropolitan Free, 2 P.M.—St. Mark's for Fistula and other Diseases of the Rectum, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
TUESDAY.....Guy's, 1½ P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.
WEDNESDAY....St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY.....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY......Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY.....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY. Royal Medical and Chirurgical Society, 8.30 P.M. Mr. Spencer Wells, "On Ovariectomy"; Dr. Drysdale, "Against Use of Mercury in Syphilis"; and other papers by Mr. T. Smith, Dr. B. Howard, Mr. Gant, Mr. J. L. Clarke, Dr. Fenwick, and Dr. Sutton.—Zoological.—Ethnological.

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

ERRATUM.—At page 625 of last number, column I, line 45, for "expend", read "expend".

THE GRIFFIN TESTIMONIAL FUND.—SIR: At a meeting of the Committee on the 12th instant, it was unanimously resolved that the above Fund should be finally closed on October 1st proximo. Intending subscribers would oblige by forwarding their contributions. The following subscription has been further received:—Haynes Hardwicke, Esq. (Saxlingham), 5s.

Amount previously announced, £124:11:9. Received at the *Lancet* office, £9:9.

I am, etc.,

ROBERT FOWLER, M.D.,
Treasurer and Hon. Sec.

145, Bishopsgate Street Without, June 22nd, 1865.

IS CAPTAIN GROSVENOR A HOMŒOPATH?—The captain, in reference to the subject of Dr. Tweedie's letter to him, has written as follows to the *Morning Post*.

"As the medical profession is in the act of pausing for a reply, and as, moreover, it is peremptory in the demand that such reply shall be immediate and final, perhaps you will allow me in your columns to state that I have no bias in favour of any particular variety of medical practice; but that, being firmly attached to the principles of liberty, I uphold every man's right to his own opinion, and to a practical expression of it as far as is consistent with the law. I am, therefore, resolutely opposed to anything like persecution arising from difference of opinion, whether in religious, political, or scientific matters."

There can be no doubt that the captain's liberal opinions are perfectly correct; and, in accordance with them, he will of course admit that Dr. Tweedie and every other medical man has "a right to his own opinion", even if the "practical expression of it" should be the refusal to vote for a promoter of homœopathy. Dr. Tweedie in so doing is not guilty of intolerance or persecution; he simply gives, as the captain calls it, a "practical expression" to his opinion.

ELECTION OF FELLOWS OF THE ROYAL SOCIETY.—SIR: Thanks for your remarks on the Royal Society, etc. I have been somewhat behind the scenes there for some years. The elections are, for the most part, carried by favour. Men who are utterly unknown to science are elected, while those who have done good work, but who are in our profession, are rejected. You would do well to compare the names which are now suspended with those of the elected during the last four or five years. I am, etc.,
June 8rd, 1865. M.D.

A QUESTION OF MEDICAL ETIQUETTE.—SIR: Will you be kind enough to give your opinion on the following case.

The husband of an old patient of mine (who is from home for the recovery of her health, on my recommendation) is suddenly taken ill. The friends (not relatives) send for the nearest medical man; he attends the case until the return of the wife, when she, finding that her husband does not improve, sends a note for me, requesting my attendance. In the note, she distinctly states that she told the gentleman in attendance on the case that she intended to send for me. She does not ask me to meet him in consultation. After I saw and prescribed for the patient, and just when I was about to leave the house, the wife said: "Will you see Mr. C.?" Thinking that this question referred to the treatment that had been previously adopted, I replied: "There is no occasion for it." Now, was I, upon this remark of the wife, and considering my previous position in regard to the patient and his wife, bound to call upon Mr. C., to consult with him as to the treatment of the case? An answer in your Notice to Correspondents will oblige. I enclose my card. I am, etc.,
June 1865. A MEMBER.

[It does not appear that Mr. C. was dismissed from attendance on the case. Indeed, from the wife's asking "A Member" to see Mr. C., we might conclude that she looked upon the meeting as a consultation. Under these circumstances, we think "A Member" would have done well to have seen Mr. C. before taking charge of the case. EDITOR.]

SUBSCRIPTIONS.

THE following Laws of the Association will be strictly enforced:—

15. The subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association of the current year. The subscriptions shall date from the 1st of January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

T. WATKIN WILLIAMS, General Secretary.

Birmingham, June 1865.

COMMUNICATIONS have been received from:—Dr. KELEBENE KING; Dr. WATERS; Dr. SYNNOT; Mr. A. B. STEELE; Dr. JOHN R. WARDELL; Mr. H. W. FREEMAN; Mr. EADON; THE HONORARY SECRETARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY; Mr. W. GRAHAM; Dr. ALLFREY; Dr. H. JACKSON; Dr. H. BARBER; Mr. T. O'CONNOR; Mr. H. B. SPERGIN; and Dr. THORNTON.

Aërated Lithia Water. —

Messrs. BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original Manufacturers under Dr. GARROD'S instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE or AMMONIA. —Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47, Piccadilly.

Important Notice to the Profession.—

SSION.—PATENT (COOKED) FOOD, for INFANTS and INVALIDS.—DR. RIDGE'S PATENT.—The best wheaten flour is put into the apparatus, where every particle is brought under the uniform temperature of 212° for eight hours, which thoroughly cooks it; and as all moisture is driven off, the nutritive quality of the flour is largely increased, while it is so light and digestible that the powers of the feeblest stomach are not taxed, but can easily appropriate it. A sample for examination will be forwarded free to any medical man who may desire it.—Manufactory—Horslydown, London, S.E.

THE

MEDICAL & GENERAL PROTECTION SOCIETY OF ENGLAND.

Offices—42, Great James Street, Bedford Row, W.C.

OFFICE HOURS, 10 to 4. SATURDAYS, 10 to 2.

The objects of this Society are—

1st. The Collection of Debts for Subscribers at a commission of £5 per cent. on all sums recovered without legal proceedings up to £100; above that amount 2½ per cent. Should proceedings be taken then no commission payable except on sums under £5.

2nd. To provide Subscribers with legal advice at all times. The Solicitor to the Society is in attendance at the Offices daily.

The Subscription to the Society is £1:1 per annum for Town Subscribers, and £1:5 for Country.

Prospectuses and all further particulars may be obtained at the Offices of the Society.

JAMES CHIDWICK, Secretary.

CHOCOLAT-MENIER.

(Manufactured only in France.)

Annual Consumption exceeds 4,000,000lbs.

The healthiest, best, and most delicious Aliment for Breakfast known since 1825; defies all honest competition, unadulterated, highly nutritious, and pure. Sold in ½ lb. Packets.

Also, especially manufactured for eating as ordinary sweets, or at dessert.

Wholesale, MENIER, 23, Henrietta Street, Covent Garden, London. Retail, by all respectable houses.

Diseases of the Heart: their

PATHOLOGY, DIAGNOSIS and TREATMENT. Second Edition, revised. Post 8vo, cloth, 6s. By W. O. MARKHAM, M.D., F.R.C.P., Physician to St. Mary's Hospital, and Lecturer at the School.

"It is a pleasant task, after deliberate examination, to confirm the favourable impression already due to Dr. Markham's previous labours, and to his high standing as a practical physician."—*Medical Times*. "We shall be glad to welcome further contributions from Dr. Markham to the literature of cardiac pathology..... We may confidently recommend the second edition of his work on the heart as containing a sound exposition of the subject upon which it treats."—*Medico-Chirurgical Review*. "The most succinct, the most accurate, and the most judicious account of Diseases of the Heart yet published."—*Edinburgh Medical Journal*. "We can unhesitatingly recommend this second edition as a work which represents in a concise and practical form the present state of our knowledge respecting diseases of the heart."—*Ranking and Radcliffe's Abstract*.

JOHN CHURCHILL, New Burlington Street.

Metropolitan Counties Branch.

The THIRTEENTH ANNUAL MEETING of the Metropolitan Counties Branch will be held at the CRYSTAL PALACE, SYDENHAM, on TUESDAY, JULY 4th, at three o'clock, p.m.

President for 1864-65..... CHARLES F. J. LORD, Esq.

President-Elect for 1865-66..... EDWARD H. SIEVEKING, M.D.

After the meeting, the members and their friends will dine together: E. H. SIEVEKING, M.D., in the Chair. Dinner on table at 5.30 P.M. precisely.

A. P. STEWART, M.D.

ALEXANDER HENRY, M.D., } Secs.

74, Grosvenor Street, 31st May, 1865.

Pepsine and Pepsine Wine.—

M. BOUDAULT begs to state that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, Her Majesty's Chemist, 277, Oxford Street, London, to whom all applications respecting it must be addressed.

Third Edition of Boudault on "Pepsine", with further Remarks by Dr. Corvisart Physician in Ordinary to the Emperor of the French; edited by W. S. SQUIRE, Ph.D. Published by J. Churchill, London. May also be had of the Author, 277, Oxford St. Price 6d.

Salmon's Obstetric Binder, for

immediate use after delivery. 5s. each.

SALMON'S ELASTIC ABDOMINAL BELTS, adapted for all cases requiring support, especially for Ladies' use before and after Accouchement, from 12s. to 42s.

Elastic Stockings, from 4s. to 10s. Knee-caps, Trusses, Suspensories, Railway Conveniences, Chest Expanders, etc.

Mrs. Salmon attends upon Ladies.

HENRY R. SALMON, 32, Wignore Street, Cavendish Square, London, W. Private Door.

TO ADVERTISERS.

British Medical Journal.—

Office, 37, GREAT QUEEN STREET, LINCOLN'S INN FIELDS, LONDON, W.C. Published every Saturday.

The BRITISH MEDICAL JOURNAL is transmitted direct from the Office to between two and three thousand Members of the British Medical Association in all parts of the United Kingdom, among whom are the Medical Officers of most Hospitals and Dispensaries; and the majority of the leading members of the profession. It is also taken in by many Libraries and Medical Societies. As a medium for immediate communication with the Medical Profession, it offers excellent facilities to advertisers of books, drugs, instruments, &c.

SCALE OF CHARGES FOR ADVERTISEMENTS.

Five lines and under	£0 2 6
Each additional line.....	0 0 6
Each ten lines	0 4 6
A whole column.....	1 15 0
A page	3 5 0

When a series of insertions of the same advertisement is ordered, a reduction is made on the above scale in the following proportions.

For 6 insertions, a deduction of 10 per cent.

For 12 or 13 " " " " 20 " "

For 26 " " " " 25 " "

For 52 " " " " 30 " "

Advertisements ought to be delivered at the Office on or before the Thursday preceding publication; and, if not paid for at the time, should be accompanied by a respectable reference.

Post-Office Orders are to be made payable at the Western Central District Office, High Holborn, to THOMAS JOHN HONEYMAN (the Publisher), 37, Great Queen Street, Lincoln's Inn Fields, London, W.C.

Original Communications.

ON CERTAIN FUNCTIONAL DISEASES OF THE RETINA.

By J. Z. LAURENCE, F.R.C.S., M.B. Univ. Lond., Surgeon to the Ophthalmic Hospital, Southwark.

[Concluded from p. 637.]

I now come to speak of a very common form of partial paralysis of the retina—a form characterised by its excessively gradual and chronic character. I mean that form which accompanies strabismus.* It had been long known that persons who squinted suffered also from defective vision. But this knowledge was—and even now is—not so widely diffused as, in the interests of humanity, it should be. A squint is, even in these days, unfortunately too often regarded as a mere personal deformity, which may, or may not, according to the patient's position or prospects in life, be well left to his own taste and discretion to be cured or not.

That the exact nature of the paralysis of the retina which accompanies squinting may be completely understood, I may be permitted to make a slight digression, in inquiring whether there exists any predisposing cause that, in the first instance, induces the malady in question? In doing so, I shall limit myself to the question as it affects the most ordinary form of squint, that of a concomitant convergent one.

It had been long known that there existed a defect of the eye, which consisted in its possessing an unduly high refractive power in proportion to the length of its optic axis, and which constitutes the essence of the optical defect known as short sight, or myopia. But there is a second optical defect of the eye, which, although its existence had been also long known, had always been regarded as quite an exceptional and uncommon form of optical anomaly. We are indebted to the labours of Donders for teaching us that this second anomaly is equally common with myopia, if not more so, and of equal importance. I mean hypermetropia; which I may briefly designate as a deficiency of refractive power in the eye. Myopia is corrected by a concave lens, hypermetropia by a convex one. Now, it had further been incidentally observed by various authors, that persons who squinted inwards presented a peculiar form of assumed "short-sight", which was remedied, not by concave, but by convex glasses. I myself, some years ago, published a paper on this subject in the *Glasgow Medical Journal*, entitled "On the Short-sight of Squinters"; in which I adduced several cases of this to me at that time inexplicable apparent contradiction of facts. But after Donders had recognised the widely spread diffusion of hypermetropia, he further remarked that an overwhelming percentage of cases of ordinary convergent squint was accompanied by this optical defect. Subsequent researches have fully proved the important fact, that hypermetropia is in these cases the cause of the squint; that this latter is a mere symptom in them, and no more a substantial disease than are the eruptions of fever or small-pox.

This was a most important step. The way in which hypermetropia induces convergent strabismus

may be briefly alluded to. The eye is deficient in refractive power; it would supplement this deficiency if it could. Has it any intrinsic power of doing so? It has; in its power of increasing the convexity of the crystalline lens by contraction of the ciliary muscle. Now, in the healthy eye, this method of increasing the refractive power of the eye is what we all do when we wish to see near objects; it constitutes what is known as the adjusting power of the eye, or its accommodation. This accommodation, however, we only normally exercise when we wish to see a near object; this involves a second muscular act, that of the internal recti muscles—we, in a word, converge the eyes to the near object at the same time that we accommodate their refractive power to it. Thus, convergence and accommodation have, probably from long association, become two almost inseparably connected acts. If we converge the eyes, we instinctively accommodate them; and if we wish to accommodate the eyes, we must at the same time converge them. Now, the hypermetropic eye, in regarding a near object, must accommodate two-fold: firstly, to supplement its intrinsic deficient refraction; secondly, it has to exercise that normal amount of accommodation that all eyes have to do to overcome the divergence of the rays of light emanating from near objects. It has then, on the whole, to exert an unusual abnormally large amount of accommodation; this excessive action is often associated with excessive convergence of the eyes. In other words, the eyeballs, in many hypermetropic eyes, to see a close object critically distinct, must converge to a nearer point than that at which the object is actually situated.

Hypermetropic eyes have two choices: imperfect binocular vision or perfect monocular vision. When the latter is attained, one eye necessarily converges so powerfully inwards, as to deviate its optic axis (macula lutea) altogether away from the object which the straight eye is regarding, and, by a power of mental abstraction, ignores the images of any objects formed on its retina. Of course, there remains still a residuary evil—that of a want of binocular vision; this the patient has no further power of correcting. Why most hypermetropic patients prefer imperfect definition to squinting, and what secondary circumstances predispose to the one or the other state, are points which it would lead us too far to discuss in the present paper. The squint is, when it first takes place, not permanent; but occurs only when the patient fixes his eyes intently and attentively on any particular object. I have met with several patients who were perfectly conscious that they did squint under these circumstances. In one very striking instance of a man aged 42, there existed a hypermetropia of $\frac{1}{11}$. This man was always sensible of a strong squint in the one eye, whenever he wished to see an object distinctly. Moreover, what is an additional cogent proof of the dependence of strabismus convergens on hypermetropia, is that natural hypermetropics, who ordinarily exhibit neither a periodic nor a permanent squint, in many instances may be observed to do so, if we cover one eye, when they accommodate for a near object; the covered eye then often exhibits a marked inward squint. And what is still more remarkable, a normal eye made artificially hypermetropic by a concave lens exhibits the same phenomenon.

To resume; the squint is then at first periodic, and may at this stage be generally cured without an operation, by convex glasses, prisms, or Javal's stereoscopic method of ocular gymnastics.

In two cases of squint (both in myopic patients, one a convergent and the second a divergent squint), the patients before the operation never could conceive what

* This subject will be found more fully treated of in the tenth chapter of my work on *The Optical Defects of the Eye*.

amusement people could find in looking through a stereoscope: they saw no difference, whether the slides were in or out of the stereoscope. But within a few days these two patients were agreeably surprised at then, for the first time in their lives, being able to appreciate the beauties of the stereoscope. I now systematically direct all patients on whom I have operated for squint, to commence, as soon as possible, a regular daily course of stereoscopic practice. I prefer ordinary slides to Javal's wafers, as the former, by the amusement they afford, keep the patient up to his work.

I consider this a most important and interesting supplement to the after-treatment of the operation for squint. Indeed, I would go a step further, and suggest the stereoscope as a curative measure against squinting in its first (periodic) stage, correcting at the same time any coincident optical defect. That most sagacious observer, our eminent Dr. Mackenzie, has suggested (in 1854) the stereoscope as an useful exercise in *di-vergent* squint. This limitation, I respectfully submit, is unnecessary. For, if I understand the action of Brewster's stereoscope rightly, no convergence of the eyes ensues in its use. One proof of this is, that myopic patients require their reducing concave glasses to see a stereoscopic slide distinctly. One of the above patients required as high a concave as a five-inch one; I myself require a ten-inch one. Another proof is direct observation. The eyes of persons looking through a stereoscope I have always observed to be perfectly central.

The idea of utilising the stereoscope for the above purposes, must, doubtless, have occurred to others. I claim no other merit, than that of bringing the method more prominently before the profession.

After the operation for strabismus, the tendency to squint still exists, and may reassert itself in all its former intensity, if the patient do not, at any rate for all close work, use proper convex glasses.

CASE VII. I operated, by double tenotomy, on a boy aged 11, for a concomitant convergent squint of the right eye, both eyes being hypermetropic, and having an acuteness of vision (S) of about $\frac{1}{2}$. When I saw him about three weeks after the operation, I found the squint had recurred to the degree of 2" in the right eye, although I was convinced I had performed the tenotomy completely. I ordered him to wear his 1-16th inch convex neutralising glasses. When I again saw him three weeks later, and subsequently upwards of three months afterwards, the squint was quite cured, and had not returned.

In how many such cases a second operation has been unnecessarily performed, from the operator's impression that the muscle had not been "completely" divided in the first operation, I am not in a position to say.

After the squint has persisted a considerable length of time, it becomes confirmed. The eye turns in, more or less, always; and from this time forwards *its vision gradually diminishes*. This arises, I believe, from a secondary change occurring in the retina of the squinting eye, which will now form the subject of our further consideration, and which, indeed, has in the first instance induced us to offer the previous rather digressive explanation of the more intimate nature of squinting. Hypermetropia originates in a congenital smallness of the eye, especially in its antero-posterior axis; and, in a restricted sense, may be regarded as an instance of congenital arrest of development. It is not unnatural under these circumstances to suppose that the retina participates in the general want of formation; and this view is borne out by facts. The acuity of vision is generally somewhat less than normal in all hypermetropic eyes (al-

together apart from any exceptional co-existence of astigmatism), and is markedly so in all the higher degrees.

The following table contains an analysis of the acuteness of vision in 112 hypermetropic eyes which I have carefully examined during the last five years.

Acuity of Vision (S) in 112 Hypermetropic Eyes.

Degree of Hypermetropia.	Average Acuteness of Vision.
$\frac{2}{7}$ to $\frac{2}{9}$	$\frac{1}{4}$
$\frac{1}{5}$ " $\frac{1}{10}$	$\frac{1}{3}$ (nearly)
$\frac{1}{10}$ " $\frac{1}{16}$	$\frac{1}{2}$ "
$\frac{1}{18}$ " $\frac{1}{20}$	$\frac{3}{5}$ "
$\frac{2}{10}$ " $\frac{1}{30}$	$\frac{1}{3}$
$\frac{1}{30}$ " $\frac{1}{50}$	$\frac{1}{5}$ (nearly)

I had formerly been in the habit of using Mannhardt's and Jäger's types as the tests of the patient's sight. In the above table, I have reduced them to those of Snellen. In every case, with a very few exceptions, the vision has been tested by the patient's power of reading the larger types when he stood exactly twenty (English) feet from them. For this purpose I have employed Nos. 23 to 18 (inclusive).

A person (with his refraction corrected, if necessary) reading:

At 20 feet, has an acuteness of vision (S) of:		
No. 18 (Jäger)	= XVIII (Snellen)...	$\frac{20}{18} = \frac{10}{9}$
" 19 "	= XXVI "	$\frac{20}{19} = \frac{2}{3}$ (about)
" 20 "	= XXXVIII "	$\frac{20}{20} = \frac{1}{2}$ (about)
" 21 (Mannhardt)	= LXX "	$\frac{20}{21} = \frac{2}{3}$
" 22 "	= LXXXIV "	$\frac{20}{22} = \frac{10}{11}$
" 23 "	= cc (about) "	$\frac{20}{23} = \frac{2}{3}$ (about)

If these equations be not strictly true, still they are perfectly applicable to the question I wish to solve, which is one of a purely relative nature. A glance at the table proves the important fact that the acuity of vision (S) exhibits a progressive diminution as the degree of hypermetropia rises. This would tend to show, that the imperfect development of the retina proceeds *pari passu* with that of the eyeball generally.

Indeed, in one hypermetropic patient, I observed an amblyopia quite equal in amount to that which is, as I shall directly revert to, witnessed in an eye which has squinted for many years.

CASE VIII. Thomas C., an Essex schoolmaster, aged 67, consulted me in August 1863, on account of his having observed the sight of the right eye gradually failing him for the previous six months. He was so amblyopic with this eye, that with or without glasses he could read no type, however large, if it were any distance off; but with a 9-inch convex glass, he was able to read No. 19 (a very large type) at eight inches. With the left, on the contrary, he read No. 19 as far as twenty feet off with a 30-inch convex glass; and No. 1 (the most minute type) with a 9-inch convex glass at eight inches off. There existed then, firstly, a slight degree of hypermetropia; and, secondly, a high degree of presbyopia. In addition to the extreme amblyopia of the right

* When I visited Professor Donders' clinique at Utrecht in 1860, I copied, and subsequently had reprinted in London, a series of large types, with which, up to the time of Dr. Snellen's introducing his improved test-types, I determined the far-point in patients. I had always thought these large types were the ones Jäger introduced as supplementary to the third edition of his well known book of types. But Dr. Snellen, in a recent communication, informs me that Nos. 21, 22, and 23, of the ones I have for the last five years been using, are those of Dr. Mannhardt of Hamburg. I have here to express my obligation to Dr. Snellen in assisting me in forming the table of equivalents to which this note refers. In the calculations, I have neglected the fact that S decreases somewhat, especially in advanced age. This error is of no account, as but few of the cases in the table are over forty years of age.

eye, its field of vision was limited to a circumscribed area around the yellow spot. Now, the interesting fact in this case was, that both fundi oculi appeared identical. In both, the optic papilla was bright at its centre; in both, the choroidal vessels were very clearly seen; in both, the direct image was seen without an eye-piece (hypermetropic refraction); in neither, were any morbid changes to be detected. In a letter, dated Feb. 1st, 1865, he writes me, "My right eye is no better; my left as perfect as ever."

Donders has also remarked the diminution of the acuteness of vision in hypermetropic eyes. He says "that, even after the correction of the astigmatism of the hypermetropia, the acuteness of vision usually remains rather considerably below the normal." (*On the Anomalies of Accommodation and Refraction of the Eye*, p. 255.) Yet, when we come to inspect such eyes with the ophthalmoscope, we can detect nothing morbid (as we do in all the higher degrees of myopia), if we except the low degree of refractive power of the organ.

The only explanation that I can give of the amblyopia in these cases is, as I have before said, that the retina is imperfectly developed—an hypothesis which future anatomical investigation may one day verify; but which the ophthalmoscope is at present powerless in revealing. Admitting such a predisposition to imperfect visual perception, we might *a priori* assume that, in an eye which has not participated in vision for perhaps many years, the perceptive faculty of the retina becomes so blunted, or altogether practically abolished, as to constitute in it what I venture to designate as a condition of *functional paralysis*, or as Donders terms it, a "loss of physiological sensibility through psychical exclusion", or inertia.

This assumption is fully borne out by facts. Of thirty-three accurately observed cases of convergent squint, in no fewer than twenty-six was the acuity of vision of the squinting eye less than that of the usually straight eye; the average ratio of the one to the other being indeed as low as 1 to 6. What influence the age of the patient, the degree and duration of the squint, the degree of the hypermetropia, severally and jointly exert on the acuity of vision, I am not in a position to say. One fact, however, I can vouch for; that is, the utter inadequacy of the ophthalmoscope in explaining this diminution of vision—as in all the cases I have ever examined, I never remember having seen anything further abnormal than a hypermetropic refraction of the eye.

I think, then, we may fairly admit some such predisposing case, as I have above suggested, to explain the whole case. For it is a well known fact that, under other circumstances, an eye may be excluded from vision for years without any paralysis of the retina ensuing. Mr. Soden relates a remarkable case of the kind, in which he removed a cataract of seventy-six years' standing, and the patient regained her sight.*

I have myself operated on a similar case.

CASE IX. Thomas B., a middle aged man, in the employ of an eminent engineering firm, consulted me last October, on account of the sight of his right eye having begun to fail him for the last two months; so that he could not recognise a person's features at forty or fifty yards; but I found he could read No. 22 at twenty feet, and that the eye was emmetropic. Focal illumination showed that the impairment of vision was due to commencing cataract, there being several peripheral opaque striæ in the lens. On

examining his other eye, I found the pupil blocked up by dead white, perfectly opaque lens-capsule; and, on further inquiry, learnt that he had been *blind of this eye for thirty years*, from a thorn striking it when beating cover. He would not at first hear of any operation on the left eye, as he said he was convinced that it was irremediably lost. However, as he had excellent perception of light with this eye, I at last induced him to submit to an operation on it. This consisted in my removing nearly all the opaque capsule with cannula-forceps; but some lens-matter that remained behind, set up repeated attacks of slight recurrent iritis, for which I performed iridectomy. These attacks at last ceased; and he regained sufficient vision with the eye to enable him to recognise objects readily and to read a large-sized type (No. 16).

I have often been asked by practitioners, Do you recommend operating early for squint? Certainly, if the squint be confirmed, as early as possible, if the patient is not to lose the sight of the squinting eye. Such an unfortunately too common occurrence entails two evils. In the first place, the patient loses binocular vision—not so small a loss as may be imagined; and, what is more important, should he by any chance lose the sight of his straight eye—a chance to which a one-eyed person is especially liable from his imperfect power of judging of distance—from an accident, from inflammation, etc., he becomes reduced to a state of altogether irremediable blindness. A case, of another kind however, in which this very nearly happened, actually took place in a patient on whom I operated.

CASE X. A woman, 44 years of age, had had for nine months soft cataract in the right eye; but, as she had the left eye sound to go on with, she never troubled herself about the loss of sight in the other eye. But on May 23rd, 1864, she met with a very curious accident. She was a needle-woman by occupation, and had the habit of carrying her scissors suspended round her waist by a piece of elastic. A dog, seeing the scissors dangling at her side, jumped up in play and snapped at them; he did not succeed in catching them, but they rebounded from his mouth and struck the patient's left eye. On examining the eye, I found a vertical linear wound of the cornea, a wound of the upper part of the iris, the anterior chamber filled with blood, the fundus not illuminable, and vision reduced to mere perception of light. In another ten days, the eyeball was so disorganised, that I was compelled to remove it; and shortly afterwards I began to endeavour to procure the absorption of the soft cataract in the right eye by repeated punctures, extending over a period of about five months. The ultimate result has, fortunately for her, turned out most brilliant. When I last tested her vision, Jan. 19th, 1865, she was able to read No. 1 (Jäger) with her reading-glass (+3), and XL (Snellen) at fifteen feet with her distance-glass (+5). I may incidentally mention that, in this case, I adopted the expedient of having the two lenses, for reading and distance respectively, set in one (reversible) frame—a practical hint worthy of noting in all cases of operated cataracts in which only one eye is used in vision.

I shall, finally, advert to another and distinct functional disease of the eye which has been, very properly I conceive, termed by Dr. Hughlings Jackson "epilepsy of the retina." It is characterised by transitory loss of vision; the patient partially or wholly loses his sight for a varying period, and then again recovers it in all its previous integrity. The ophthalmoscope reveals no morbid conditions of the fundus oculi. In many cases, the patient has previously suffered from genuine epileptic seizures,

* A great part of the preceding remarks on convergent strabismus—written originally for this JOURNAL—is incorporated in my recent work on the *Optical Defects of the Eye*.

either amounting to actual fits, or only to an aura epileptica.

The following are two of some instances which I have seen of epilepsy of the retina.

CASE XI. Stephen P., aged 22, had had two years before I saw him an attack of epilepsy, of which (he said) the effects lasted for three days. On recovering, he found the left eye closed (ptosis), and he could not open it for seven days. From that time, he had had no further fits. He did not remember his sight failing him for any time, or immediately before the fit. What he now complained to me of was, that about once a week or fortnight he would lose his sight for a time, but that he recovered it again. I found that he was amblyopic with the left eye, and appeared to be slightly myopic with both. With the ophthalmoscope, I detected neither a hypermetropic nor a myopic refraction of the eye; the optic discs were reddish, their contours rather ill-defined; the vessels were rather small; there was an appearance of tension in the internal tissues.

CASE XII. A man, aged 21, a year ago, whilst at work, found a "mist" come over his eyes sufficiently dense to obscure objects around him. He has ever since been subject to these attacks every four or five weeks. They last for from five minutes to half an hour at a time; the average being a quarter of an hour. During an attack, he can see his way about, and even read with difficulty. He has never had any fits, but occasionally feels giddy. After one of his attacks, he feels sickish and has a headache.

I am quite aware how imperfect is the above sketch that I have ventured to offer on these obscure functional impairments of the retina. It is necessarily so, from the comparatively slight amount of attention the subject has hitherto commanded. Imperfect as it is, I trust, however, that it may prove sufficiently suggestive to induce others to follow up what I cannot help considering as a most interesting and important study, not only for the ophthalmologist, but for all who are interested in the investigation of disease generally.

CARCINOMA OF THE STOMACH.

By JOHN RICHARD WARDELL, M.D., M.R.C.P., Physician to the Tunbridge Wells Infirmary.

[Concluded from page 639.]

To attempt to assign any real or regular cause of cancer, would be at the best but a vain endeavour; and all that we can assert, in the present state of our knowledge, are mere hypotheses and vague surmises, which are either not borne out, or are absolutely refuted, by the facts which accumulated cases present. We know, however, that some occult cause, whatever it may be, effects a very potent change in the fluids; that it institutes some morbid condition of the blood capable of favouring the genesis of those flagrant cell-growths known as malignant. We see this condition in persons whose bodily conformation and external appearances are most opposite; sometimes in the ruddy and muscular, as well as in the pale and attenuated. The belief of many that it is an hereditary disease is a creed which has long been entertained, and one that is becoming still more prevalent; for certain it is that, in many instances, other members of a family are, upon inquiry, found to have died of the same disease. Nor is the acknowledgment of this transmission by inheritance at all inconsistent with what we know of the vital properties of the organism. Absolute cancerous material cannot be transmitted with the germ; but some hidden, inscrutable impress is transmissible, which impress at a remote period favours the development

of that product; and we must confess that it cannot be entirely divested of any material relations. We know that other diseases, as tuberculosis, gout, insanity, are hereditary; and there is no reason why the cancerous diathesis should not be transmitted in like manner. That constitutional tendency is, however, very greatly promoted or retarded by the operation of external agencies; and there is no doubt that a high state of civilisation conduces to its progress and results. With the exception of the uterus, there is no organ so prone to cancer as the stomach; numerical data in our own and other countries having abundantly attested this fact. Men are more decidedly prone to it than women, probably on account of their more intemperate habits, greater exposure to vicissitudes of temperature, and greater mental anxieties. Some few instances are given of its occurrence before the age of thirty. It is, however, very seldom observed before the age of thirty-five; far more frequently in those approximating fifty, and in still more advanced life. It belongs to those heterogeneous changes in the assimilation of the tissues which proclaim declension of vital power, and are intimately associated with age. There is no reason for believing that one class is more prone to it, or enjoys a greater immunity from it, than another. We meet with it in persons occupying every social position—in the well-nourished, as well as in the half-starved; in those who live in the country, as well as those who live in cities.

In the great majority of examples, it is primary cancer which affects the stomach. This organ may, it is true, be the seat of the secondary form; but such cases are mere exceptions to a great general rule. The lymphatic glands may become contaminated by the presence of the disease in neighbouring viscera; as, for example, when the head of the pancreas, the liver, the spleen, the omentum or mesentery, are affected. Some pathologists have affirmed that it is the colloid variety which is most generally found in the stomach. It would, I think, more correctly express the fact, if we say that it is the scirrhus-colloid which is most frequently met with in that particular situation—the hard, fibred basic substance upon which is superimposed the gelatiniform, locular mass. Colloid may and does coexist with the villous, encephaloid, and melanotic forms; but these combinations are not nearly so often observed. The carcinomatous matter is infiltrated into the areolar tissue; because, in such loose and comparatively unresisting structure, it there finds less opposition to its deposit. In the course of time, the muscular and other tissues become encroached upon, and cancerous cells are formed within the muscular filamentous sheaths, the molecular constituents of the muscles being absolutely displaced and occupied by the new formations. One of the great characteristics of carcinoma is displacement and occupation. The product which is substituted not only does not possess the secretory capabilities of the parts removed, but it gravely interferes with the functions of the organ or organs which it has selected as its *habitat*. Again, the vitiated secretions, which are poured out into a hollow viscus, confer additional disorder. Carcinoma of the stomach fully illustrates this evil. The large jelly-like mass, by mixing its perverted exudations with the gastric juice, so injuriously operates upon the normal qualities of that fluid as to render it quite unequal to the due performance of its office; hence one cause of the sour ejections, the dyspepsia, the occasional attacks of diarrhoea, and that gradual diminution of flesh and strength, which an impaired chyme must inevitably produce. The encephaloid variety grows most rapidly; the scirrhus most slowly. Scirrhus and colloid may exist in the stomach for

years before they destroy; the encephaloid will produce a fatal issue in the course of a few months. The one typifies the acute, the other the chronic form. The encephaloid and scirrhus are considered to give the most pain; the colloid the least. The loculi or alveoli, which are so characteristic of the colloid, are formed simply by irregular infiltration; they vary in size and configuration, according to the circumferential pressure, the amount of fibrous tissue, and their deep or superficial position. In the stomach and peritoneum, the colloid mass is more diffuse and less nodular than when deposited in glandular structures. Microscopic investigation has in latter years cleared up much that was previously obscure respecting the ultimate structure of cancer; and, by this acquired knowledge, diagnosis has been rendered much more certain than it was when mainly based upon clinical observation and empirical practice. Cancer-cells are regarded by Lebert as modified lymph-cells, often monstrously altered in size. Collis says they present more or less resemblance to typical forms; and in any specimens there will be much variation in the size and outline of individual cells, yet with much elementary similarity in the tumour. Lebert describes the colloid cells as being large, pale, oval, round, or tubular, lying in clusters. There are also small granular irregularly shaped corpuscles, which are regarded as cancer-cells hindered in their development. The pyloric end of the stomach is most prone to carcinoma; next in frequency, the cardiac orifice; after that situation, the lesser curvature. The splenic end is least liable to the affection. It is a curious fact—nevertheless, one which is true—that the deposit is rarely or never seen to extend into the duodenum; and the only reason why this abrupt termination thus obtains appears to be, that the duodenum is far more scantily supplied with areolar tissue than the stomach. The mass may present much resemblance to effused lymph; and it should not be forgotten that lymph will sometimes be deposited in the walls of the stomach, especially towards the pylorus, to considerable extent. But the malignant growth is much less uniform in its configuration; and there is not superficial softness in mere lymphic deposit. When the disease pervades the cardiac orifice, the growth will extend into the œsophagus, and cause organic stricture. When the liver becomes secondarily affected, the germs are transferred by the lymphatics and the veins, especially by the latter; because, it should be remembered, the gastric veins run to the liver. The reason why the lungs are not implicated in carcinoma of the stomach, is supposed to be on account of the cancer-cells being too large to pass through the hepatic lobular plexus. When the liver has become carcinomatous, sometimes unevenness and pitting may be felt on its surface. I have known this in marked manner when there has been much emaciation. The stomach is often found agglutinated to the liver, and more especially when the disease is at the pylorus. When the growth at the pyloric orifice becomes considerable, the pylorus will fall into the right iliac fossa, simulating tumour or impaction at the ileo-cæcal junction. I recently saw a case which I believe to be very illustrative of this fact. Rokitsansky has known the pylorus to touch the symphysis pubis. We have seen in Case iv above recorded, that even when the mass hangs from the lesser curvature, the pain may be chiefly referred to the right fossa. This is a fact which, in a practical point of view, is of much importance. This falling down can, of course, only be when there is no attachment to neighbouring viscera. On reference to Case iv, it is stated that the patient was always in the least pain when in the

erect position. The autopsy fully explained this peculiarity. The mass was pressed upon in the sitting or lying postures; but, on the resumption of the erect position, it would hang tolerably free in the gastric cavity.

The symptoms by which this formidable disease can be recognised are, in the earlier date of the affection, often obscure, and by no means easy of interpretation. When it has made progress, the diagnosis becomes comparatively easy. Sometimes it happens that the complaint has considerably advanced before it was even suspected. Again, it occasionally occurs, as Dr. Watson has remarked, without from first to last presenting any pathognomonic symptoms at all. It usually begins with dull, aching pain at the epigastrium, sour eructations, and an uneasy feeling of fulness and distension, which are at first merely attributed to indigestion; afterwards, there are loss of appetite, depression of spirits, and, curiously enough, an unwonted petulance and irritability of temper. The tongue is comparatively clean; nor is there any symptomatic fever. Costiveness, alternating with occasional attacks of diarrhoea, supervenes, doubtless caused by undigested food and that butyric fermentation which the unhealthy secretions from the cancerous surface are known to produce. No symptom, however, augurs greater import than the loss of flesh; and, if accompanied with the yellowish dusky cachexia, in addition to the more obvious and ordinary symptoms, the prognosis must needs be most unfavourable. When the ordinary stomachic remedies fail, and the wasting goes on, there can be but little doubt of malignancy. As the complaint advances, vomiting generally comes on. In two of the foregoing cases, it came on immediately after eating. In both, the disease was at the cardiac end of the stomach. In Case ii, where there was partial stricture of the œsophagus, the food was instantly rejected. In all the cases, the ejections were invariably sour. Sometimes there will be mixed with the glairy mucus black or coffee-grounds looking flakes, the results of hæmorrhagic exudation, or the erosion of some of the smaller vessels; or there may be active hæmorrhage. This symptom is in the latter stage. At the first, simple ulcer may be simulated; but, in simple ulcer, the pain is not so persistent, nor so sharp and lancinating; it occupies but a small area; and the rest of the mucous membrane is healthy, and there is little or no loss of flesh. When the orifices are not obstructed, sickness is less urgent, and the patient lives longer. When the pylorus is the seat, a special train of phenomena supervene. This orifice becomes gradually narrower until positive occlusion well-nigh results; the imperfectly digested food can then but with great difficulty pass through the contracted portals; the stomach labours to overcome the obstruction; and the applied hand can feel a vermicular movement resulting from its efforts. By this excess of action, and the abnormal gases which are generated by perverted secretion, the organ becomes large, and percussion elicits preternatural resonance. When there is constricted pylorus, the intestines are empty, and the belly drawn in—a condition which is seen in some other forms of disease; for example, in typhus, when there is diminished chyle and great deoxidation of the tissues. When the cardiac orifice is the seat of the tumour, the swallowed morsel gives rise to pain immediately after its descent into the œsophagus. There will then be instant rejection, or (Case ii) the food will feel to stick as it were at the epigastrium; and the pain to which such obstruction gives rise is excessively severe. When the growth is in the lesser curvature, it very generally extends to one or both orifices. In Case iv, it did not do so. Sickness may

be a distressing symptom even when the inlet and outlet are free from disease. The mental faculties usually keep clear to the last. In all of the above examples, this was the case.

I have said the diagnosis is more difficult at the first than afterwards. When the affection has progressed, palpation will assist the formation of an opinion very materially. Pressure gives pain at some circumscribed spot. This pain often radiates through into the back. Frequently, a large, irregular, hard substance can be felt in the right epigastric region, between the mesial line and the right false ribs. The movement of this substance gives pain. When the cardium is the site of the growth, some thickening can be discerned (after emaciation has progressed) towards the splenic end of the organ. The patient's description of the pain should never be disregarded. Sharp, stabbing, hot, burning, were terms employed by the patients whose cases have been given above. We should bear in mind that the pain may simulate that of renal calculi, of ordinary hepatic pain, of tumour in the posterior mediastinum, of abdominal aneurism, of lumbago. There may, however, be but little pain, as sometimes little vomiting, from first to last. I have known carcinoma of the uterus be attended with scarcely any pain. If the branches of the par vagum enter the mass, there will be great suffering. If the tumour lie in front of the abdominal aorta, it will be lifted up by the pulsations, and simulate aneurism. Negative and stethoscopic facts will, however, guard us against such a mistake. In chronic or acute irritation of the gastric mucous membrane, the pain is diffuse, and referred to the entire epigastrium—not circumscribed as in malignant tumour. The ejected matters will assist in some measure in arriving at a correct diagnosis, not only as regards the true nature of the disease, but as to its particular position in the organ. Under the microscope, cells of a specific character can, on careful examination, be discovered mixed with the vomited fluids. If the growth be at the pylorus, the food will be partially digested; if at the cardium, it will generally be little altered. If there be much blood, we should suspect the encephaloid or melanotic variety. Notwithstanding all the foregoing rules for observation, necroscopy will from time to time reveal conditions unsuspected, and disappoint us by not displaying those which we had anticipated.

Some time ago I was requested by Mr. Hutchinson of Lamberhurst to see with him a patient who had long been affected with persistent stomach-disease. There was no very decided cachectic expression; yet he got thinner, and his condition caused anxiety. The tongue was livid, flabby, smooth, creamy; the appetite impaired; the epigastrium full and resonant. Pressure gave pain, which was not localised, but diffused over the whole region. There was pain after meals, but no vomiting. The urine was voided in normal quantity; specific gravity 1015; excess of triple phosphates. I gave it as my opinion, notwithstanding the loss of flesh and other doubtful symptoms, that his case was not malignant. Mineral acids, bitter infusions, morphia at bedtime, and a regulated diet, were followed by gradual improvement; and for more than twelve months he has been quite well. An in-patient was admitted into the infirmary under my care several months ago, in the person of a tall, powerful woman, who had been servant in a gentleman's family. For more than half a year she had had epigastric pain, and more especially after eating. She looked sallow, anæmic; and had become thinner. Her spirits were much depressed, and she believed she laboured under a fatal malady. A medical opinion had been given sus-

pecting cancer. I was written to by the lady with whom she had lived, respecting her going into the Cancer Hospital. The epigastrium was rounded and resonant; no tumour; no hardness; and pressure gave diffuse dull pain, which did not lancinate into the back. Tongue creamy, flabby, not loaded. Right hypochondrium duller than normal. I expressed my decided opinion that her affection was not cancer. A blister to the epigastrium, a mixture with infusion of rhubarb and calumba and the bicarbonate of soda, with small doses of strychnine, mild mercurial alteratives, and an easily digested and nourishing diet, were followed by speedy improvement. She soon left the hospital well, and her health continues good at this date.

In saying a word relative to treatment, there cannot be much discrepancy of opinion upon this head. When we are impressed with the belief of the existence of malignancy, the remedies can only be palliatives, or at most such as are deemed to possess the power of retarding the progress of the complaint. All depressing mental emotions should be avoided, as well as every description of ingesta which might irritate the lining membrane of the stomach. The food should be light, digestible, and nourishing. Solids are to be utterly discarded. The various farinaceous articles of diet are to be taken; and these may be advantageously given in combination with soups, broths, and jellies; new laid eggs, milk (mixed with lime-water when there is acidity), pounded meats, and like bland articles of food. With regard to medicines, the nitrate of bismuth, as a mineral astringent, has been much lauded. It may be given in combination with hydrocyanic acid and some bitter infusion. When there is excess of acidity, the aqua calcis is preferable to the other antacids. If this be not employed, Brandish's alkaline solution, with some aromatic water, will be found serviceable. Morphia, henbane, and conium I have found of great service, even at the earlier stage, in tranquillising the nervous system and giving sleep. When the disease shall have advanced, morphia is the all-important remedy. When sulphuretted hydrogen is developed, the creasote pills produce much benefit. The bowels may be regulated by pills of aqueous extract of aloes, extract of belladonna, and quinine. An opium and belladonna plaster to the stomach has a comforting effect; and towards the close, when the pain becomes excessive, opiate epithems are not to be omitted. When the stomach will not retain food, nutritive enemata may advantageously be employed.

DANGER OF INJECTIONS INTO ANEURISMS. A man in the Aix Hospital had a traumatic aneurism of the brachial artery at the elbow-joint. Compression was tried for a month, but failed. M. Goyrand therefore injected into the tumour five drops of perchloride of iron. The aneurism at once became firmer, the thrill of it ceased, the pulsation in it was less, but still continued. A second similar injection was therefore tried. Immediately thereupon the whole hand became pale; the sensation in the fingers was most painful; the temperature was lowered. The hand was like that of a dead person. All pulsation of the tumour had ceased. Frictions and hot applications were applied to the hand. On the next day, a blue circle was seen at the finger and gradually increased. Deep pain was felt in the hand. Eventually the hand was separated at the wrist by dry gangrene, and the man left the hospital cured in a month. The accident was accounted for by supposing that a clot of fibrine had been driven into the ulnar and radial arteries.

British Medical Journal.

SATURDAY, JULY 1st, 1865.

IS THE COLLEGE OF SURGEONS PROPERLY GOVERNED?

It may be well for us to take this particular occasion of the College of Surgeons' election of Councillors, to bring prominently before the profession its anomalous government; and thereby to illustrate the necessity (so long insisted on by us) of a reconstruction of its Charters. The time will soon come, we venture to prophesy, when the profession will not only cease to wonder at our persevering criticisms of the Institution, but will express surprise that such a government could have ever existed.

Assuredly, the present Charters are not suited to these times. They were obtained by those who had command of the entire good things of the College—who regarded those things as, in some sense, their private property; and having, were resolved to keep, the possession in their hands. Unfortunately, the spirit which directed the acts of those who were in power when the present Charters were obtained, has steadily survived even to the present time; but it is a spirit which is dissonant from common sense and common justice, and which, therefore, cannot long survive the judgment of modern opinion. And, happily, we can see approaching the end of misrule; and we think that we may fairly claim the thanks of the profession for having been the first to attack in earnest the bad system; to lay bare its unseemliness; and to point out the right path of reform.

When we first spoke of, and as, year after year, we insisted on, the necessity for a new Charter, votes by voting-papers for country Fellows, and separation of the Court of Examiners from the Council of the College, we excited the ridicule of some and the wrath of others. But what a change has since come over Fellows' minds! The old system of re-election of Councillors has been ruthlessly arrested; and now candidates for the Council find themselves compelled to make the most liberal confession and promises as the passport to their admission! Ay! candidates enter the Council pledged to assist in obtaining the very reforms which we have so long been maintaining as essential! Could a more striking justification be given of the propriety of the course which we have steadily and firmly pursued in this matter?

The inquiry which we now propose to make may be entered into by asking, What is the meaning of the annual and eager contest for seats in the Council?

The answer is, it is the annual contest for a desirable, but *in futuro*, prize—an examinership—for

an office which, when obtained, it is the practice to hold for life; and worth, some say, at least £400 a-year.* Few, indeed, are they who seek the Councillorship solely for the purpose of being Councillors.

The office of Councillor is merely a post of moderate honour and of considerable labour. It is not worth, in a money point of view, the outlay it involves. The fees to be paid by a Councillor, on taking office, are twenty pounds; and a man must be a long time in office before he recoups himself this sum.

But why, an ordinary person might say, should a Fellow, who has no mind for the work, be forced to pass perhaps eight, ten, or even more years in the Council in order that he may become an Examiner? Does the Charter require this? No! nothing of the kind. The Charter says that Fellows who are not on the Council, may be elected Examiners. But the Council—or rather the Court of Examiners, which rules the Council—say:—We will do nothing of the kind; we know what is wanted better than the Charter does; the office of Examiner is, and always has been, the property of senior London surgeons, and descends to them according to seniority. The older men are, the better Examiners they make; and, at all events, custom and old habits lead us to regard the office as our legitimate property, and we mean to hold to it as such. As for electing as Examiner a man not on the Council, merely because he is a first-rate teacher of anatomy, or physiology, or surgery, it is out of the question, and contrary to all precedent. Mr. Paget and Mr. Hewett might (as you say) make very good Examiners; but the idea of elevating them, young men, over the heads of numbers of their seniors, grey haired veterans, who are, and have been long, waiting their proper rotation turn of seniority for the coveted prize, is really outrageous! Their turn will come all in proper time. To be sure, some six or eight years hence, they may not be quite as well up in physiology and anatomy, as they now are; but then they will know quite as much as others do, and quite enough for the purpose of choosing good surgeons. The lucrative office of Examiner is (as we determine it) vested in, and appertaining to, London surgeons, to be held by them according to seniority, and held for life. Fellows, as far as we can manage it, shall come into the Council according to seniority; and from the Council they shall, as vacancies occur, and according to their behaviour there and antecedents, be draughted into the Court of Examiners.

Now let us note the necessary practical working of this mode of dealing with the Examinerships.

* On this, as on so many other points, the Council do not think it right to give the profession any distinct information. The fees of Examiners are in the published balance-sheet of the College expenditure, mixed up under the same head with "coals, law expenses, wages, salaries, diploma stamps, auditors, etc." This compound item of disbursement—including *Councils and Examiners' Fees!*—in the list for 1861 (lying before us), amounts to £-831.

As Examiners, by the system of quinquennial re-elections, virtually hold office for life, and as Examiners are (by the system) all chosen out of the Council, vacancies in the Examinerships are few and far between. Then, as the practice, till lately, has been to re-elect retiring Councillors, and to elect new Councillors from the College list of Fellows according to seniority, Fellows do not become Councillors until at about (on an average) the mature age of from 50 to 60. Then, again, as they must necessarily remain several years in office as Councillors before their "turn" comes for being made Examiners, it can rarely happen that a man is made Examiner before the age of 60 and upwards. And thus it is that, long after men have ceased to teach surgery, long after they have ceased to study or teach anatomy and physiology, both whilst overwhelmed with the cares of large London practice, and even after they have retired from practice, they still hold the office of Examiner.

And now, we ask, Is this system in accordance with the best interests of the College and of medical science? No one will, we suppose, assert that Examinerships were established for the benefit of senior London hospital surgeons; and no one will, we think, venture to assert that it is for the best interests of the profession that they should be held solely by London surgeons according to seniority. Nevertheless, it is thus that they have hitherto been held, and held contrary to the spirit and intention of the Charters under which Examiners are elected. Thus, in truth, the very evils which the last Charters were obtained to remedy are still maintained in vigorous operation.

Surely, therefore, we are thoroughly justified in making this inquiry—in asking, Is the government of the Royal College of Surgeons carried on in full accordance with the best interests of medicine? Are not the interests of medicine sacrificed to private interests? Surely we are so justified, when we find the express intentions of the Charters ignored by those who govern under them; when we see the College governed, not by the spirit, but by the letter of the Charters.

We will venture to say, that not in the wide world can such another system of management be found in operation, as that which at present prevails in the Royal College of Surgeons of England. Let us for a moment try the system, by seeing how Examiners are elected in other kindred corporations.

We suppose every one will concede that the system of the University of London may be regarded as something approaching to a model system; to one which represents the opinion of the present day. Now, the Examiners of the London University are elected *annually* by the Senate. No member of Senate is eligible as an Examiner; and no Examiner is eligible for election more than four years consecutively. Ex-

aminers, moreover, are elected out of the whole body of the profession.*

And let us see who the men are, thus elected by those whose sole object is to put the right men in the vacant places—to get the best Examiners. Are they taken by seniority, as at the College of Surgeons? Nothing of the sort. The London University selects for its Examiners men of the following stamp—men of the following age and standing in the profession: Drs. Sibson, Parkes, Tyler Smith, West, Braxton Hicks, Priestley, Frederick Farre, Garrod, Habershon, Guy, and Odling; Messrs. Hilton, Erichsen, Viner Ellis, Redfern, Savory, and Huxley. These are the sort of men selected for Examiners by those who do not assist in electing themselves, and whose only object and desire are to get the best men for the work.

The men whom we have here named are chosen Examiners by the London University, all in the strength and vigour of their age and scientific labours; and all of them up to the level of the science of the day. Do not their very names, as selected Examiners, irresistibly condemn by comparison the system of self-election by seniority which prevails in Lincoln's Inn Fields?

Then, again, we ask, on what principle of right or reason is it that the Examinership of the Royal College of Surgeons should be held for life? One of the express objects of the Charter was to do away with these life-appointments. But of what avail was the introduction into the Charter of quinquennial election of Examiners, if Examiners are systematically re-elected into office, and virtually re-elected by themselves? Will any one believe—will the Council of the College venture to assert—that this system of life-holding of Examinerships is the system best adapted to the interests of the College and of the profession?

Let us see how it works. Under this life system, only a comparatively very small number of the Fellows of the College can ever become Examiners. But why should the public, and the profession, and the College, be deprived of the services of the many highly educated surgeons and anatomists found in the body of Fellows of the College; and solely in order that a privileged few may enjoy the benefits, and, as it is very wrongly regarded, the rights of life-Examinerships?

And, we ask, again, why should not these very high and much sought for prizes of Examinerships be open to distinguished men of science of the rising generation of Fellows—open to them, also, at a time when the very money value of the prize would be an

* The Senate, in fact, advertise annually for and elect candidates; the Examinerships being open to all qualified candidates. Since these lines were written, we see, by an advertisement, that Dr. Sibson resigns his Examinership because he has been elected to the Senate of the University. But the College of Surgeons does exactly the reverse. It says: You shall not be an Examiner unless you are in our Senate.

exceeding boon—during the early struggles of professional life? On what principles of right, reason, or justice, is the good thing to be bestowed upon those only who have already won their way to wealth and honour and advanced age, who are, it may be, overwhelmed with the business of private practice, and to whom the mere duties of Examinership must be ever a weariness and a drudgery?*

Surely, it is not because a bad system has been long permitted to exist, and has become (so to say) consecrated by time and custom and familiarity, that therefore it should be for ever continued; and what can the warmest defenders of the system here spoken of say in its defence, except that "it has been the custom."

Such a state of things can only exist so long as the profession is ignorant and apathetic, but cannot long survive the force of professional sentiment when brought to bear against it. To expose is to condemn it.

And we would observe that, in saying all this, we say it not to the blame of individuals, but to the condemnation only of the system which has been passed into their hands for administration. Our sole desire is to rescue the College from the unfortunate groove in which it is running; and we believe its rescue is to be found only in a new Charter. The College possesses, and has long possessed, powers enough under its present Charters for its reformation; but it has never used those powers. As every one knows, many Fellows have of late years entered the Council on reforming principles, under the idea of compelling the Council to obey the spirit of the Charter. But what have they effected? They enter the Council; and we hear no more of them, or of their promises, until their names are announced as Examiners, or until they offer themselves for re-election as Councillors! Never yet in one single instance has the Council carried into action the new and liberal spirit of its latest Charter. It has power to elect, as its President and Vice-President, Councillors who are not members of the Court of Examiners; but it has never done so. It has power—we might say it is enjoined by its Charter—to elect as Examiners Fellows who are not members of Council; but it has never done so; it has invariably elected members of Council only. Examiners once held office for life; but, under the present Charter, they are elected to office for the

term of five years only, and are so elected for the very purpose of doing away with the life-holding system. Being, however, re-eligible, the Examiners have been invariably re-elected to office by the Council, or rather we should say, by themselves; the Examiners' influence being predominant within Council. And in this way has the office of Examiner been maintained as a life-office, contrary to the spirit and the very intention of the new Charter; and in this way have been maintained the worst evils of the old system, spite of the Charter which was obtained for their express removal.

Despite, therefore, of the "infusion of new blood", as it is called, into the Council, despite of the election (from which so much was expected) of *soi-disant* reformers into the Council, all these things negating and violating the spirit of the Charter still go on just as they have ever done. Therefore have we lost faith in reforming candidates for office. We blame them not; it is the system which is at fault. *Les choses sont plus fortes que les hommes.* In Council, the Fellow soon finds he must forget the lessons which he learnt and the promises he made out of office. The temptation to discretion is great; and the value of the wise word, "Silence is gold," is soon forcibly brought home to him within the Council-chamber. A reforming Councillor must of necessity be antagonistic to the Court of Examiners. But to have the Examiners (who rule in Council) hostile to the Councillor is to have that Councillor excluded from the benefits of a seat in the Court of Examiners. And therefore is it most evident that only a new Charter can bring relief—a Charter which *compels*, not simply permits, the Council to carry its spirit into action. That a new Charter must, at any rate, be had, is certain; for it is impossible much longer to refuse to the country Fellows that small modicum of justice which they claim—a vote by voting-papers.

In conclusion, we would say that, in what is here set down, we sincerely believe that we have not misstated in the smallest particular the actual facts; and we can most conscientiously repeat, that we have thus plainly detailed them for one only object—the good of the profession—to enlighten the general ignorance of the profession on the subject. We believe that our medical brethren, from one end of the kingdom to the other, will agree with us that it is not well for the profession that the Examiners of the College of Surgeons should be elected to office at sixty years of age and upwards; nor that, being so elected, they should hold office for the remainder of their lives;* that it is neither right nor well that Examiners should assist in electing and re-electing themselves to office; and that it is not well that the

* On this score, we may usefully quote the words of Sir B. Brodie, as taken from his *Autobiography*: "My own view of the matter is, that while hospital surgeons somewhat advanced in their profession should be the principal element in a Court of Examiners, it will be well to have conjoined with them a certain number of younger men, fresh from their anatomical studies, who, not being much engaged in practice, would have more leisure to bestow on the anatomical part of the examination than the elders of the profession." And the words of Mr. Lawrence, spoken thirty years ago before a Committee of the House of Commons: "I think that many competent Examiners might be found between the age of 25 and 36; and, if men of sufficient eminence could be found younger than 36, I see no objection to their being Examiners."

* Calculating from the date of membership, as given in the College list, the following represents, we believe, a pretty accurate view of the ages of present examiners; 82, 76, 69, 67, 66, 65, 63, 62, 60.

mere seniority of Fellows as London and hospital surgeons should be the accepted passport to the office of Examiner.† We firmly believe that every impartial member of the profession, when master of the facts of the case, will agree with us that the connexion of the Council with the Court of Examiners is an unnatural connexion; that no Examiner ought to be a member of Council, or assist in his own election; and that, in truth, the presence of Examiners in the Council is the main producer of all the evils we here tell of; that Examiners should be elected annually, and elected by the Council indifferently from out of the whole body of Fellows—the best men being taken, independently of age or seniority; that no Fellow should hold office as Examiner for more than three or five years, nor be eligible for re-election when his term has expired; that the prize of an Examinership should not be reserved for a few favoured senior London surgeons, but that it should be open to all Fellows of the College, and bestowed on those to whom it would naturally be given if the Council had no other object in view in the election than that of obtaining for the College the most competent Examiners.

THE LOCALISATION OF SPEECH.

M. VELPEAU has for the moment rather puzzled M. Bouillaud, who has again been ventilating, in the Academy of Medicine, his favourite theory of the localisation of speech in the anterior lobes of the brain. M. Bouillaud has, it appears, offered a prize to any one who can produce a case of lesion of the anterior lobes unaccompanied with affection of the speech. To this prize M. Velpeau says he thinks to lay claim. "No one," replies Bouillaud, "is more worthy of it."

"What I fear is," rejoins Velpeau, "that your prize will be like Delpech's. Delpech asserted that it was impossible to cure fracture of the neck of the femur without deformity, and offered 2,000 francs to any one who could show him such a case. To all the cases, however, which were sent to him, he took exception; but, having at last become convinced of the fact, he announced in the journals that he had at length himself met with such a case, and had, therefore, adjudged the prize to himself!"

M. Bouillaud replied to the spiritual Velpeau, that he was not a Gascon,* though he lived near Gascony; and that he should certainly with pleasure give the prize when gained. The prize was small, it is

true; but, if he had been in M. Velpeau's position, he would have made it ten times greater.

"As for the amount of the prize," replies Velpeau, "that signifies nothing; if I gain it, I shall give it to the Medical Benevolent Fund. My case is this. In 1844, a most talkative *perruquier* entered La Charité for incontinence of urine. He was remarkable for his incessant loquacity, his jokes, and his cynicism. He died at the end of seventeen days, but never ceased talking. The day of his death, he spoke, and answered properly all questions. There was nothing to suggest any disease of the brain. The brain was examined incidentally; and the anterior lobes were absent. They were, in fact, both of them replaced by a tumour as large a hen's egg, of a scirrhous nature. What says M. Bouillaud to this case?"

"If M. Velpeau will present me a similar case," was the reply, "I will give him the prize."

"Oh," says M. Velpeau, "the case is perfectly authentic, and on record. There is no need of a second case."

M. Delpech then joins in, and declares that he himself had made the autopsy; that he had presented the specimen to the Anatomical Society; and that the case was unanswerable. Says M. Bouillaud:

"I declare the fact impossible, and that the *interne* who made the autopsy witnessed a miracle! You may call me mad, if you please; but I will never believe that an injury of the two anterior lobes of the brain can exist without any disturbance of the speech or of the intelligence."

M. Velpeau: "I think M. Bouillaud is going beyond the limits of scientific discussion. It is a matter of indifference to me where the regulation of speech resides. I have no wish to upset M. Bouillaud's theories. But, after all, we must confess that we know very little about the functions of the brain; and it seems rash at present to localise a faculty in any particular part. As for a second case, I certainly shall not attempt to find one; it belongs to the future; and the demand reminds me of the amusing reply of the embalmer Gannal. He assured us that his process would preserve bodies for two thousand years; and, when we told him he was joking, he replied, 'Well, you will see!'"

M. Bouillaud then asked the Academy to appoint a committee to decide whether the prize was gained; but M. Velpeau, having told his tale, declined to have anything to do with it.

On the 27th ultimo, Dr. Acland of Oxford delivered the Harveian Oration at the Royal College of Physicians, before a very crowded audience. The Prince of Wales, Mr. Gladstone, and other celebrities, were present. Dr. Acland devoted his discourse to a discussion of the doctrine of final causes. He especially referred to Comte's denial of the doctrine, as exemplified by him in the case of the crystalline lens. Comte asserted, that the lens was not only of no use, but that it was worse than useless, in that in its diseased state it prevented the use of the eye. Dr. Acland showed, by reference to very recent ophthalmological observations, the error of this crucial in-

* In 1834, the late Sir B. Brodie said on this point before a Committee of the House of Commons:—

"With respect to the College of Surgeons, I can say first what the Court of Examiners ought not to be. The mode of electing them ought not to be that which it is at present (1831). The Examiners are now appointed according to seniority, or nearly so. The Examiners ought to be those of whom there is reason to believe that they are the best qualified for the office, whether they are the younger members of the body or the older ones."

In the sense of these very words were the new Charters of the College framed; but, nevertheless, thirty years after they were spoken, the very system which was condemned by Sir B. Brodie and Mr. Lawrence, and which those Charters were to have reformed, is still in as vigorous operation as ever!

* Gascons are notorious jokers!

stance of Comte's—the exact use of the lens having been demonstrated. The lens has been shown to undergo alteration of form during vision, so as to adapt the organ to the varying distances of objects. Dr. Acland paid an eloquent tribute to the genius of Harvey; and deduced from his writings the conclusion that his method of observation was correct; that he did not allow his scientific observations to be swayed by any theological dogmas; but followed out the true path of scientific research fearlessly and to the end. There are hopes and distant aspirations, Dr. Acland said, which science cannot satisfy. This Harvey acknowledged; and admitted also that there were sentiments which the heart alone can feel. Dr. Acland's oration was a most highly polished address, worthy of the University which he represented and of the College. This was the first occasion on which it was ever given in English; and we think we may safely say, that it was never listened to by a more numerous audience, consisting mainly of the *élite* of the profession.

In the House of Commons last week, Lord C. Paget was asked by Sir J. Pakington,

“Why surgeons in the Royal Navy had been recently appointed to do assistant-surgeons' duty, and if it be owing to a scarcity of the latter officers, or that there are no candidates on the list for admission into the medical service of the navy; and if the Admiralty had taken any steps to remove so great an evil. To this he replied, that several young surgeons had been lately appointed on promotion, particularly on foreign stations, in order to retain their services on board ship, and with the view of keeping young surgeons well employed, as there was always more or less difficulty in keeping the places of assistant-surgeons filled, there being so much employment for them elsewhere. The Admiralty were certainly not in a great want of assistant-surgeons; but the young surgeons were employed to do surgeons' duty with the view of keeping them from going into private practice. The Admiralty did not think it necessary to take any steps for giving additional facilities for assistant-surgeons entering the service.”

Now, this answer is a complete official blind, and a direct perversion of the real facts of the case, which, as we are informed on the best authority, are as follows. It is positively true that there are at the present time no naval assistant-surgeons available for service, and that there are no candidates for office on the list; the necessary consequence of which is, that the authorities are forced to appoint surgeons to do assistant-surgeons' duty. Moreover, all our naval hospitals are in want of assistants, and none are to be had. Lord C. Paget, indeed, deserves the praise of having exercised the highest art of officialism on this occasion; viz., of taking credit for excellent management, whilst explaining away a truth most damaging to the credit of the department over which he rules. If we remember rightly, this is not the first time he has shown ability in this crafty art of statesmanship. The statement that young surgeons

are appointed to do assistant-surgeons' work, in order to keep their hands in, is, we are informed, accurately untrue. They are so appointed out of pure necessity; viz., because assistants are not to be had. Lord Paget, again, speaks of *young* naval surgeons out of employ as if they were as plenty as blackberries. We have heard, of late, nothing but complaints of slowness of promotion; and have, therefore, no belief whatever in the abundance of these *young* surgeons. Now here, as we said a few weeks ago, is a case in which the profession has the game distinctly in its own hands. Will it play it out successfully? Will it take warning from the error committed in the case of the Army Medical Department? Let medical candidates only continue to abstain from applying at the Admiralty, and the required reform in the Naval Medical Department is secured. We urge our professional brethren to do their best to prevent candidates from offering their services to the navy until those services are duly acknowledged by proper treatment.

An application has been made to the College of Physicians by the Committee appointed in France to carry out the erecting of a monument to Dr. Jenner. Our readers may remember that the scheme is of very many years' standing; but it is now likely to be soon carried out. By decree imperial, permission has been lately obtained for raising the statue at Boulogne. But the Committee are still met with a difficulty—want of funds—to complete the design. The College, considering the liberality shown by France, America, and other foreign nations, in subscribing to the monument of Jenner once erected in Trafalgar Square, and afterwards removed to Kensington Gardens for the admiration of nurses and children, have decided to forward £25 for the purposes of the Boulogne statue.

THE College of Physicians, on the 26th ult., adopted a letter drawn up by the President and Censors, addressed, in the name of the College, to the Secretary of War and the First Lord of the Admiralty. The letter calls attention to the fact of discontent being universal in the army and navy medical services; that our best men do not enter those services; and that medical lecturers throughout the kingdom advise their pupils not to enter them under present conditions. The College deplores, for the sake of the soldier and the sailor, this unfortunate state of things—this antagonism between the profession and the public services; and respectfully hopes that the army and navy authorities will take steps to remove the sources of discontent, which must necessarily be seriously prejudicial to the interests of the soldier and the sailor. The College expresses a belief that a return to the Warrant of 1858, a guarantee of its

being faithfully carried out, and the giving of a definite position to the army and navy medical officers, would remove the discontent now existing, and be the means of inducing the best educated men to enter the service. The College has, in fact, we are glad to see, accepted the recommendations of its own Committee; but, instead of making an appeal to Parliament, has thought it better to write to the Secretary of War and the First Lord of the Admiralty.

THE Metropolitan Counties Branch will hold its thirteenth annual meeting at 3 P.M. on Tuesday next, under the presidency of Dr. Sieveking. The meeting will be followed by a dinner at half-past five, at which also Dr. Sieveking will take the chair. We trust that the high professional position of the President on the occasion, and the esteem in which he is held by his brethren, will secure a full attendance of the members of the Branch and of their friends. We are glad to learn that the Branch is in a prosperous state; and that its numerical strength will present an increase over that of last year.

At the recent annual meetings of the Lancashire and Cheshire and of the South-Eastern Branches, resolutions in favour of the BRITISH MEDICAL JOURNAL were proposed and carried without dissent. The vote of the Lancashire and Cheshire Branch, proposed by Dr. Waters and seconded by Mr. Steele of Liverpool, was:

"That the members of the Branch desire to express their entire satisfaction with the JOURNAL, and to record their undiminished confidence in the ability and judgment displayed by the editor in its management."

The South-Eastern Branch, on the 22nd, agreed to the following resolution, proposed by Mr. Heckstall Smith of St. Mary Cray, and seconded by Dr. Carpenter of Croydon.

"That, in the opinion of this meeting, the JOURNAL has greatly improved under the management of Dr. Markham, and is worthy of support."

We can honestly say that we have endeavoured to raise and maintain the character of the JOURNAL; and, naturally, we feel highly gratified and encouraged by these repeated and independent expressions of confidence in our management of it, on the part of the Branches of the Association.

Professor Matteucci has been nominated to the post of Director of the Museum of Natural History in Florence, in the room of the late Marquis Ridolfi.

Dr. Giuseppe Giglioli, Professor of Anthropology in the University of Pisa, has lately died. He for some time practised law at Bologna, but in 1831 was obliged to expatriate himself; and, after taking the degree of M.D. in Edinburgh, he practised medicine in England until his return to his country in 1848.

Association Intelligence.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-third Annual Meeting of the British Medical Association will be held at Leamington, on Tuesday, Wednesday, Thursday, and Friday, the 1st, 2nd, 3rd, and 4th days of August next.

President—G. E. PAGET, M.D. Cantab.

President-elect—S. J. JEAFFRESON, M.D. Cantab.

The Address in Medicine will be delivered by W. STOKES, M.D., Regius Professor of Physic in the University of Dublin.

The Address in Surgery will be delivered by JAMES SYME, F.R.S.Ed., Professor of Clinical Surgery in the University of Edinburgh.

Gentlemen intending to read papers, cases, or any other communications, are requested to give notice of the same to the General Secretary, at their earliest convenience.

T. WATKIN WILLIAMS, *General Secretary*.

13, Newhall Street, Birmingham, May 16th, 1865.

REPORT OF MEETING OF COMMITTEE OF COUNCIL:

Held at Birmingham, June 22nd, 1865.

PRESENT—Sir Charles Hastings, M.D., D.C.L., etc. (in the Chair); Mr. Bartleet; Dr. Bryan; Mr. Clayton; Dr. Falconer; Dr. Richardson; Mr. Southam; Dr. Stewart; Dr. Wade; Dr. Wilkinson; and Mr. Watkin Williams (General Secretary).

Resolved: That this Committee is desirous to co-operate with the Medical Association of Ireland in forwarding the objects stated in Dr. Mackesy's letter.

Resolved: That the public, under the privilege of the President, be permitted to attend the meetings of the Association at which the discussions take place. (a.) On Scientific Medicine. (b.) On State Medicine.

Resolved: That the Report of the Charter Subcommittee, the Draft-Charter, and the Petition to Her Majesty, be printed as a supplement to the BRITISH MEDICAL JOURNAL, at as early a date as possible.

The Report to be presented at the Annual Meeting was approved of.

The Programme for the Annual Meeting was approved of.

T. WATKIN WILLIAMS, *Gen. Sec.*

13, Newhall Street, Birmingham, June 26th, 1865.

BRANCH MEETINGS TO BE HELD.

NAME OF BRANCH.	PLACE OF MEETING.	DATE.
METROPOL. COUNTIES. [Annual.]	Crystal Palace, Sydenham.	Tuesday, July 4th, 3 P.M.
NORTH WALES. [Annual.]	Royal Hotel, Rhyl.	Tuesday, July 4, 12 noon.
WEST SOMERSET. [Annual.]	Clarke's Castle Hotel, Taunton.	Tuesday, July 4, 2.30 P.M.
BATH AND BRISTOL. [Annual.]	Philosophical Institu- tion, Bristol.	Thursday, July 13, 4.45 P.M.
EAST ANGLIAN. [Annual.]	Council Chamber, Town Hall, Ipswich.	Friday, July 14th, 2 P.M.

METROPOLITAN COUNTIES BRANCH.

THE Thirteenth Annual Meeting of the Metropolitan Counties Branch will be held at the Crystal Palace, Sydenham, on Tuesday, July 4th, at 3 P.M.

President for 1864-65 CHAS. F. J. LORD, Esq.

President-elect for 1865-66... E. H. SIEVEKING, M.D.

After the meeting, the members and their friends will dine together; E. H. SIEVEKING, M.D., in the Chair. Dinner on the table at 5.30 P.M. precisely.

A. P. STEWART, M.D. } Hon. Secs.
ALEXANDER HENRY, M.D. }

74, Grosvenor Street, June 1865.

WEST SOMERSET BRANCH.

THE Annual Meeting of the West Somerset Branch will be held at Clarke's Castle Hotel, Taunton, on Tuesday, July 4th, at 2.30 P.M.; HUGH NORRIS, Esq., President.

Gentlemen are requested to give notice to the Secretary of cases or papers they may wish to communicate.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, June 1865.

NORTH WALES BRANCH.

THE Sixteenth Annual Meeting of the North Wales Branch will be held at the Royal Hotel, Rhyl, on Tuesday, July 4th, at 12 noon; JOHN R. HUGHES, M.D., President.

Gentlemen who may have papers and cases to communicate, will be good enough to forward the titles of the same without delay to the Secretary.

Dinner at 3 P.M.

D. KENT JONES, *Hon. Secretary.*

Beaumaris, June 1865.

BATH AND BRISTOL BRANCH.

THE Annual Meeting of the Bath and Bristol Branch will be held in the Philosophical Institution, Bristol, on Thursday, July 13th, at 4.45 P.M.; when R. W. FALCONER, M.D., President, will resign the Chair to F. BRITTAN, M.D., President-elect.

The dinner will be held at the Volunteer Club, Bristol, at 6.30 P.M.; F. BRITTAN, M.D., in the Chair.

HENRY MARSHALL, M.D. } Hon. Secs.
R. S. FOWLER. }

Clifton, July 26th, 1865.

EAST ANGLIAN BRANCH.

THE Annual Meeting of the East Anglian Branch will be held in the Council Chamber, Town Hall, Ipswich, on Friday, July 14th, at 2 P.M.; A. H. BARTLET, M.D., President.

Dinner at 5 P.M.

Members are requested to forward to Dr. Chevallier the titles of any papers or cases they may wish to communicate, on or before June 30th.

B. CHEVALLIER, M.D., *Hon. Secretary.*

Ipswich, June 14th, 1865.

HULL BRANCH: ANNUAL MEETING.

THE second Annual Meeting of this Branch was held at the Vittoria Hotel, on June 13th, 1865, at 5 P.M.; J. DOSSOR, Esq., President, in the Chair. The meeting was numerously attended; many visitors also being present.

Officers for 1865-6. All the officers were unanimously re-elected.

Papers. The following papers and communications were made.

1. Idiopathic Tetanus. By J. H. Gibson, Esq.
2. A Peculiar Form of Goitre. By K. King, M.D.
3. Poisoning by Strychnine. By H. Munroe, M.D., F.L.S.

4. A Peculiar Form of Abscess, with Microscopic Examination of Contents. By W. Hendry, Esq.

5. The Detection of Organic Impurities in Water. By T. Walton, Esq.

The papers read at the meeting will be forwarded for publication in the JOURNAL.

Dinner. At half-past six o'clock, an excellent dinner was provided at the Vittoria Hotel. The President (J. DOSSOR, Esq.), as an old member of the Association, made some very encouraging remarks as to the progress which the British Medical Association of late years had made. He hoped shortly to see the names of many more members of the profession added to its list. The profession at large had derived already much benefit from the Association; and, by unanimity of feeling and co-operation of its members, much good might yet be accomplished.

A very interesting discussion too place, as to the gratuitous services of medical men to charitable institutions.

Dr. MUNROE hoped the time would soon arrive when every member of the profession would be amply and justly paid for his services; and that charitable institutions, the noblest monuments of England's greatness, would yet reward the medical man for his labours. If the members of the medical profession would be true to themselves, the remedy for the grievance is in their own hands. Mr. BROWNIDGE, Mr. CARNLEY, and Mr. GIBSON advanced further arguments in favour of the services of medical men being remunerated. Dr. KING, with great judgment and much charitable feeling, spoke somewhat in favour of the present system carried on at most of our charitable institutions, believing that the medical officer's true and independent position would be interfered with if he were paid for his services. Many other topics were broached and discussed by the members, tending to the advancement of the *status* of the medical man. A very pleasant evening was passed.

BIRMINGHAM AND MIDLAND COUNTIES
BRANCH: ANNUAL MEETING.

THE Annual Meeting of this Branch was held at the Hen and Chickens Hotel, Birmingham, June 13, under the Presidency of Dr. JAMES RUSSELL. There were also present, T. J. Anbin, Esq. (Kingswinford); E. Bartlett, Esq. (Campden); T. H. Bartlett, M.B.; J. Bassett, Esq.; C. E. Busigny, Esq. (Ombersley); H. D. Carden, Esq. (Worcester); T. A. Carter, M.D. (Leamington); M. H. Clayton, Esq.; H. Downes, Esq. (Handsworth); T. Ebbage, Esq. (Leamington); D. Everett, Esq. (Worcester); G. Fayrer, M.D. (Henley-in-Arden); A. Fleming, M.D.; Bell Fletcher, M.D.; B. W. Foster, M.D.; J. S. Gaunt, Esq. (Alvechurch); Dr. Harrison (Walsall); G. Jones, Esq.; F. Jordan, Esq.; E. S. Machin, Esq. (Erdington); J. Manley, Esq. (West Bromwich); F. A. Nesbitt, Esq. (Wolverhampton); Langston Parker, Esq.; J. Scurrah, M.D.; H. E. F. Shaw, Esq. (Sutton Coldfield); J. V. Solomon, Esq.; T. Swain, Esq.; W. F. Wade, M.B.; C. Warden, M.D.; T. Watkin Williams, Esq.; G. Yates, Esq. (Paradise Street).

Report of Council. Dr. WADE (Honorary Secretary) read the Report of the Council, which congratulated the members upon the continued success of the Branch, as shown by the number of its members, and by the excellence of the papers which had formed the subject of discussion during the past year. The

formation of the Medical Provident Society was dwelt upon as the most important medical event of the last twelve months; and the members were strongly urged to take advantage of its provisions. The Council also congratulated the Branch upon the excellence of its choice in electing Mr. Bartleet of Campden, Dr. Fayer of Henley-in-Arden, and Mr. John Clay of Birmingham, as its representatives on the Board of Directors of the Medical Provident Society. The experience of these gentlemen (particularly of Mr. Clay, who drew up the tables afterwards approved by Mr. Finlaison) had been of the greatest service in starting the new movement upon sound financial principles.

The Report was adopted, and ordered to be entered on the minutes.

The Report of the Treasurer (Mr. Watkin Williams), which had been audited by Mr. Alfred Baker and Mr. Clayton, was also approved and adopted.

Election of Officers and Council. Dr. T. A. Carter of Leamington was unanimously appointed President-elect for the ensuing year.

The following appointments were also made.

Members of Council. Country Members: E. H. Coleman, Esq. (Wolverhampton); D. Everett, Esq. (Worcester); G. Fayer, M.D. (Henley-in-Arden); J. S. Gaunt, Esq. (Alvechurch); W. J. Kite, Esq. (West Bromwich); J. E. Male, Esq. (Leamington); H. E. F. Shaw, Esq. (Sutton Coldfield); W. Smith, Esq. (Redditch). *Town Members:* Alfred Baker, Esq.; M. H. Clayton, Esq.; J. Clay, Esq.; J. J. Hadley, Esq.; F. Jordan, Esq.; Langston Parker, Esq.; Oliver Pemberton, Esq.; J. F. West, Esq.

Representatives of the Branch in the General Council of the Association. Alfred Baker, Esq.; E. Bartleet, Esq.; H. D. Carden, Esq.; M. H. Clayton, Esq.; D. Everett, Esq.; G. Fayer, M.D.; O. Pemberton, Esq.; J. Russell, M.D.; and W. F. Wade, M.B. (*ex officio*).

Directors of Medical Provident Society. Sir Charles Hastings, M.D.; H. D. Carden, Esq.; and G. Fayer, M.D., were elected.

President's Address. The President (Dr. RUSSELL) then delivered a very apposite and thoughtful address, for which a vote of thanks was accorded to him by acclamation.

Dinner. The members and their friends subsequently dined together at the Hen and Chickens Hotel—Dr. Russell in the Chair, and Dr. Carter (President-elect) in the Vice-chair; and a most agreeable evening was spent.

EXTRAORDINARY LONGEVITY. The obituary in *The Times* of June 21st and 22nd, contain some rare illustrations of prolonged life, in the case of six ladies and the same number of gentlemen whose united ages amounted to 1,044 years, giving an average of exactly 87 years to each; the eldest lady having reached 94 and the youngest 81 years of age, the eldest gentleman being 95 and the youngest 81 years of age.

UNIVERSITY OF LONDON. Dr. Sibson has been elected a member of the Senate of the University of London, and has therefore resigned his Examinership in Medicine at the University. The appointment is in the hands of the government; but at every third election of Senate, convocation is permitted to send up three names, and the government selects him who has the largest number of votes. Dr. Sibson on this occasion had the majority, 280 votes. In consequence of Dr. Sibson's election to the Senate, a vacancy occurs in the office of Examiner in Medicine at the University. Candidates must send in their applications to the Registrar before July 8th.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. At a general meeting of the Fellows, held on Monday, June 26th, 1865, the following gentlemen, having undergone the necessary examination, were duly admitted members of the College:—

Cheadle, Walter Butler, M.D. Cantab., 8, Old Cavendish Street
Leighton, Edmund Thomas, M.B. Cantab., 4, Henrietta Street, Cavendish Square

At the same meeting, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the science and practice of medicine, surgery, and midwifery, were duly admitted to practise physic as Licentiates of the College:—

Belcher, Paul, Burton-on-Trent
Birtch, John, M.D., Fingal, Canada West
Collins, Charles Phillips, Maidstone
Evans, John Tasker, M.D. Aberdeen, Hertford
Moore, Thomas, Cradley Heath
Plowman, Richard, Bridgewater
Pointon, James, Huyton, Lancashire
Thursfield, Thomas William, M.D. Aberdeen, Kidderminster

The following gentlemen were reported by the examiners to have passed the *first part* of the Professional Examination for the Licence of the College:—

Arnold, John, St. Bartholomew's Hospital
Budd, Herbert Golding, Guy's Hospital
Burn, William Barnett, St. Bartholomew's Hospital
Dalton, Benjamin Neale, Guy's Hospital
Elliott, Arthur Bowes, Guy's Hospital
Lamb, Barnabas Walter, St. Bartholomew's Hospital
Morris, Henry, Guy's Hospital
Parsons, Frederick William, King's College
Plowman, Richard, St. Thomas's Hospital
Randall, John George, St. Mary's Hospital
Sedgwick, Henry, St. Bartholomew's Hospital
Square, William, St. Bartholomew's Hospital

Fellows elected on June 26th:—

Austie, Francis E., M.D. Lond.
Dickinson, William H., M.D. Cantab.
Hicks, John Braxton, M.D. Lond.
Keinion, George, M.D. Edin.
Roberts, William, M.D. Lond.
Sankey, William H. O., M.D. Lond.
Washbourn, Thomas E., M.D. Lond.

APOTHECARIES' HALL. On June 22nd, 1865, the following Licentiates were admitted:—

Jeffreys, Richard, Portland Road Villas
Lucas, Herbert, Hitchin
March, John, New Wandsworth, Surrey
Marriott, Henry Thomas, Colston Bassett, Notts
Mason, Samuel, Teignmouth, Devon
Rowlands, James David, Carmarthen

At the same Court, the following passed the first examination:—

Cheetham, Joseph Priestnall, Guy's Hospital
Smith, Frederick Walter, St. Thomas's Hospital

APPOINTMENTS.

*WELLS, J. Soelberg, Esq., elected Professor of Ophthalmology in King's College.

ARMY.

CHAPPEL, Staff-Surgeon R. A., to be Surgeon Royal Artillery.
CLARK, J. E., Esq., Assistant-Surgeon 22nd Foot, to be Assistant-Surgeon 38th Foot, vice T. Wright.
CUNY-GHAME, Staff-Assistant-Surgeon R. J. B., M.D., to be Assistant-Surgeon Rifle Brigade, vice A. Guthrie, M.D.
DEMPSTER, Staff-Surgeon C. C., to be Surgeon Royal Artillery.
DRYSDALE, Staff-Surgeon A. K., to be Surgeon Royal Artillery.
GALBRAITH, Staff-Surgeon-Major G. T., M.D., to be Surgeon 71st Foot, vice W. Barrett, M.B.
GALBRAITH, Staff-Surgeon-Major G. T., M.D., from half-pay, to be Staff-Surgeon-Major, vice A. K. Drysdale.
GASCOYNE, Staff-Assistant-Surgeon G. E., to be Assistant-Surgeon Royal Artillery.
GIBAUT, Staff-Surgeon W. M., to be Surgeon Royal Artillery.
GIBBONS, Surgeon J., 95th Foot, to be Surgeon Royal Artillery.
GIRAUD, Staff-Assistant-Surgeon B. T., M.D., to be Assistant-Surgeon 19th Hussars, vice G. R. Woolhouse.

HINTON, Staff-Assistant-Surgeon J., to be Assistant-Surgeon 10th Hussars, *vice* I. G. Hooper.
 HOOPER, Staff-Surgeon L. G., to be Surgeon 104th Foot.
 HUTTON, Staff-Assistant-Surgeon G. A., to be Assistant-Surgeon 71st Foot, *vice* A. G. Young.
 KELLETT, Staff-Surgeon E. Y., to be Surgeon 101st Foot.
 MACBETH, Staff-Surgeon A. M., to be Surgeon 105th Foot.
 MACLEAN, Staff-Surgeon A., to be Surgeon Royal Artillery.
 MENZIES, Staff-Surgeon-Major E., to be Surgeon 19th Hussars.
 MENZIES, Staff-Surgeon R., to be Surgeon Royal Artillery.
 MILLS, Staff-Surgeon W. W., to be Surgeon Royal Artillery.
 MURPHY, Staff-Surg. T. J., to be Surgeon 95th Foot, *vice* J. Gibbons.
 NOOTT, Surgeon E. G., from half-pay, late 2nd Foot, to be Surgeon 108th Foot.
 O'DWYER, Staff-Assistant-Surgeon T. F., M.D., to be Assistant-Surgeon 20th Foot, *vice* J. E. Clark.
 POLLARD, Staff-Surgeon W. H., to be Surgeon 22nd Foot, *vice* R. B. Smyth, M.B.
 REID, Staff-Surgeon T. B., to be Surgeon Royal Artillery.
 RENNIE, Staff-Surgeon D. F., M.D., to be Surgeon 20th Hussars.
 RICKETTS, Staff-Surgeon C., to be Surgeon Royal Artillery.
 SINCLAIR, Staff-Surgeon E. M., to be Surgeon Royal Artillery.
 SMYTH, Surgeon R. B., M.B., 22nd Foot, to be Surgeon 102nd Foot.
 STUART, Staff-Assistant-Surgeon J., to be Assistant-Surgeon 13th Foot, *vice* P. N. Jackson.
 THOMPSON, Surgeon-Major J. A. W., M.D., 86th Foot, to be Surgeon-Major Royal Artillery.
 TURNBULL, Staff-Surgeon G. A., to be Surgeon 21st Hussars.
 WOOLHOUSE, Assistant-Surgeon G. R., 19th Hussars, to be Staff-Assistant-Surgeon, *vice* B. T. Giraud, M.D.
 WRIGHT, Staff-Surgeon T., to be Surgeon 80th Foot, *vice* Surgeon-Major J. A. W. Thompson, M.D.

To be Staff-Surgeons:—

CHAPPLE, Assistant-Surgeon R. A., Royal Artillery.
 DE CHAUMONT, Staff-Assistant-Surgeon F. S. B. F., M.D., *vice* E. M. Sinclair, M.D.
 DEMPSTER, Staff-Assistant-Surgeon C. C.
 DUNLOP, Staff-Surgeon J. M.D., from half-pay, *vice* E. Menzies.
 GUTHRIE, Assistant-Surg. A., M.D., Rifle Brigade, *vice* R. Menzies.
 HOOPER, Assistant-Surgeon L. G., 10th Hussars.
 HUISE, Staff-Surgeon H., M.D., from half-pay, *vice* G. A. Turnbull.
 HUMFREY, Staff-Assistant-Surgeon A., *vice* A. M. Macheth.
 JACKSON, Assistant-Surgeon P. N., 13th Foot, *vice* W. W. Mills.
 KELLETT, Staff-Assistant-Surgeon E. Y.
 LUNDY, Staff-Assistant-Surgeon E. L., *vice* T. B. Reid.
 MACLEAN, Assistant-Surgeon A., Royal Artillery.
 MURPHY, Assistant-Surgeon T. J., M.D.
 POLLARD, Assistant-Surgeon W. H., Royal Artillery.
 RICKETTS, Assistant-Surgeon C., Royal Artillery.
 WOODMAN, Surgeon G. T., M.D., from half-pay, 39th Foot, *vice* D. F. Rennie, M.D.
 WRIGHT, Assistant-Surgeon T., 38th Foot.
 YOUNG, Assistant-Surgeon A. G., 60th Foot, *vice* W. M. Gibaut.

MILITIA.

SPURGIN, H. B., Esq., to be Assistant-Surgeon Northamptonshire and Rutland Militia.

VOLUNTEERS. (A.V.=Artillery Volunteers; R.V.= Rifle Volunteers):—

FINLEY, H., M.D., to be Assistant-Surgeon 31st Lanarkshire R.V.
 MAURITZ, R. H., Esq., to be Honorary Assistant-Surgeon 7th Cheshire R.V.
 PERRY, R., M.D., to be Surgeon 31st Lanarkshire R.V.
 YEARNAN, G., M.D., to be Assistant-Surgeon 31st Lanarkshire R.V.

KING'S COLLEGE. Mr. Soelberg Wells, Ophthalmic Surgeon to King's College Hospital, has been elected Professor of Ophthalmology in King's College.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. On June 26th, the following officers were elected for the ensuing year. *Censors:* A. Farre, M.D.; W. R. Basham, M.D.; H. Davies, M.D.; G. Johnson, M.D. *Treasurer:* J. Alderson, M.D. *Registrar:* H. A. Pitman, M.D. *Librarian:* W. Munk, M.D. *Examiners:*—(a) *On the Subjects of General Education:* F. Hawkins, M.D.; W. Munk, M.D.; H. Thompson, M.D. (b) *On the Subjects of Professional Education. Anatomy and Physiology:* C. H. Jones, M.B.; W. O. Markham, M.D. *Materia Medica, Chemistry, etc.:* G. O. Rees, M.D.; A. S. Taylor, M.D. *Principles and Practice of Medicine:* T. A. Barker, M.D.; W. H. Walshe, M.D. *Midwifery and the Diseases peculiar to Women:* C. West, M.D.; R. Barnes, M.D. *Principles and Practice of Surgery:* C. G. De Morgan, Esq., F.R.C.S.; H. Coote, Esq., F.R.C.S. *Curators of the Museum:* J. Alderson, M.D.; G. H. Roe, M.D.; W. Wegg, M.D.; F. Sibson, M.D.

EPIDEMIOLOGICAL SOCIETY. A meeting of this Society will be held on Monday, July 3rd, at 37, Soho Square, when Dr. Weber will read a paper, communicated by Dr. Hirsch of Berlin, on the outbreak of cerebro-spinal meningitis in the district of Dantzic.

SURGEON TO THE QUEEN FOR SCOTLAND. We understand that Mr. James Spence, Professor of Surgery in the University of Edinburgh, has been appointed Surgeon in ordinary to the Queen, in room of the late Dr. David MacLagan. (*Edinburgh Courant.*)

A MEDICAL CERTIFICATE. Mr. Longfield while detailing the Wilde "scandal" in the House of Commons, thus spoke of a medical certificate. "And now I come to a gentleman, Mr. Hey, the surgeon of Leeds, who must be held to be a man of honour and conscience, and who was almost the only one that was not implicated with the Bethell family."

ARRIVAL OF DR. PRITCHARD IN EDINBURGH. On the 26th ult. Dr. Pritchard was brought to Edinburgh from Glasgow. The prisoner on alighting smiled at the curiosity that was manifested by the passengers, and talked apparently at his ease to the officer as he proceeded to the cab which was in waiting in front of the station. He was handcuffed.

DEATH OF DR. FERGUSON. The death of this eminent physician is announced to have taken place on Sunday last, at his residence, Ascot Lodge, Winkfield, near Windsor. The deceased gentleman was physician extraordinary to the Queen, as well as physician-accoucheur to her Majesty. He was formerly physician-general to the Lying-in Hospital, and principal physician and also professor of midwifery at King's College Hospital. He was the author of various medical productions, among which his work *On Puerperal Fever* is best known.

THE CASE OF MR. DEBENHAM. Last week the body of Thomas Solomon, the ship's painter, which had been hurriedly buried by the parish undertaker of Mile End Old Town three days after he was shot by Mr. R. Debenham, a surgeon, was exhumed by order of the Home Secretary. The exhumation of the body was carefully conducted at 7 o'clock in the evening in the presence of the deceased's brother, Mr. Smith, Mr. Thompson, a surgeon in the Mile End Road, appointed by Mr. Lewis, sen., of Ely Place, on the part of the accused, and a military surgeon and his assistant appointed by the Home Secretary. The body was in a rapid state of decomposition. The head was opened by the medical men appointed by the Home Secretary, and upon careful examination it was found that the ball had entered the left temple, passed right through the skull, and imbedded itself in the bone at the posterior part of the skull. The ball was removed, and the cause of death and the direction it had taken being most clearly established, the body was again buried.

THE CASE OF SHOOTING BY A SURGEON. At the Thames Police Court, on Monday, Mr. R. Debenham, surgeon, surrendered on his recognisances to answer a charge of manslaughter in killing Thomas Johnson. Mr. F. Tothill, surgeon, said that the body, when examined, was much decomposed. At the junction of the left temple with the parietal bone, a wound of somewhat circular form was detected. The blood was extravasated under the scalp, and permeated the whole of the cellular membrane. On removing the scalp, a similar hole was found corresponding with that on the temple; and the occipital bones were extensively fractured. The ball was found firmly imbedded in the right occipital bone at the back of the skull, two inches from the right ear, and somewhat

below it. The ball had taken an oblique direction from the left temple, just above the eye, to the back of the head, below the right ear. The wound was, no doubt, the cause of death. The distorted and jagged appearance of the ball was not caused by striking the temple and bones of the skull. The ball must have struck some hard substance before it entered the skull, which was unusually thin. The ball was a common conical ball. The ball was not found embedded in the thickest part of the bone, but in that bone in which the thickest part is placed. Mr. Lewis said the evidence of Mr. Tothill supported his theory that Mr. Debenham never fired at the deceased; and that the ball struck the brick wall, the corner of which was chipped, and, from the deflection, struck the deceased. Mr. Paget remarked, that the valuable evidence given by Mr. Tothill proved the wisdom of the step adopted by the Home Office, in ordering the exhumation of the body. The Magistrate committed the prisoner for trial for manslaughter, taking the same bail as before, Mr. Debenham's own personal recognisances in £4,000, and four responsible householders in £1,000 each.

OPERATION DAYS AT THE HOSPITALS.

WEDNESDAY...St. Mary's, 1 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—St. Bartholomew's, 1.30 P.M.
THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Great Northern, 2 P.M.—London Surgical Home, 2 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.
FRIDAY.Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.
SATURDAY....St. Thomas's, 1 P.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock, Clinical Demonstration and Operations, 1 P.M.—Royal Free, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY. Epidemiological Society, 8 P.M. Professor Hirsch (of Berlin), "On the Outbreak of Cerebro-Spinal Meningitis in the district of Dantzic."—Entomological.
WEDNESDAY. Obstetrical Society of London, 8 P.M. Association Medical Officers of Health (Anniversary).

TO CORRESPONDENTS.

*. All letters and communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen St., Lincoln's Inn Fields, W.C.

COMMUNICATIONS.—To prevent a not uncommon misconception, we beg to inform our correspondents that, as a rule, all communications which are not returned to their authors, are retained for publication.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

THE COMING ELECTIONS.—We are glad to hear that Mr. Clement has a very excellent chance of being successful as candidate to represent Shrewsbury in Parliament.

DEFERRED COMMUNICATIONS.—Owing to the pressure on our space arising from the publication of the Index in the present number, we are obliged to defer some reports of Branch meetings and other communications.

THE COUNCIL OF THE COLLEGE OF SURGEONS.—SIR: Hearing that a report is in circulation that I am no longer a candidate for the Council of the College of Surgeons, may I beg of you to state that such report is not correct.

I am, etc.,
Savile Row, June 29th, 1865.

CHARLES HAWKINS.

THE COLLEGE OF SURGEONS.—Dr. Marriott, F.R.C.S., Surgeon to the Leicester Infirmary, thus writes to us concerning Mr. Quain's claims to re-election to the Council of the College of Surgeons:—"Mr. Quain has, for years past, stood nearly alone in the advocacy of a more liberal action in the Council of the College of Surgeons. Mr. Quain has for many years been pre-eminently active in bringing forward liberal measures in the Council of the College of Surgeons; and, if they had been given force to, that College would no longer be the type of all that is slow and obstructive; would no longer need changes and advances forced upon it; but would stand forth as the vanguard among liberal educational institutions. Four times in the last ten years has Mr. Quain brought forward a motion for an annual meeting of the Fellows, at which the Council shall be present; all changes in voting, in examinations, etc., to be laid before the Fellows for their approval. Another motion, strongly urged by Mr. Quain, was, that no member of the Council shall be an Examiner; that the Court of Examiners shall consist of two sets—one of younger men, Fellows and Teachers of Anatomy and Physiology; the other of older men, to examine in Practical Surgery, etc.;—both sets of Examiners to be appointed for a limited period. Again, Mr. Quain attempted for some years, in vain, to establish a publication of the proceedings in the Council, with the names of the movers and seconders of resolutions, and a record of the votes of each member at divisions. During the past year it has been carried that a calendar, with an abstract of the proceedings, shall be published. He also attempted to make the Fellowship more accessible, without invalidating the searching nature of the examination. In 1848, Mr. Quain proposed that the Membership Examination should be divided, as it is at present; but he was told it was 'impossible'. In 1857, however, it passed into law, mainly through his efforts. Mr. Quain has not talked about 'reform'; but devoted his best energies, and struggled against a majority, to establish those principles of a free and liberal education, which, in the conscientious discharge of his duty, he felt to be for the advancement of the best interests of the whole medical profession."

AN OLD ADVERTISEMENT.—SIR: I met a few days ago with the enclosed advertisement, taken from a newspaper, date 1794. It might interest some of the readers of the JOURNAL.

I am, etc.,
Clifton, June 22nd, 1865.

CROSBY LEONARD.

"Pregnant ladies, whose situation require a temporary retirement, may be accommodated with apartments to lie-in, agreeably to their circumstances; and depend on being treated with honour, attention, and secrecy; their infants put out to nurse, and humanely taken care of, by applying to Mr. White, surgeon and midwife, or Mrs. White, midwife, No. 2, Loudon-House Yard, the north side of St. Paul's Church Yard. Where may be had the Restorative Salo Pills, at £1:2 per box, an effectual remedy to remove all obstructions and irregularities. Also, Mr. White's Address to the Community, respecting Concealed Pregnancy, well worth the attention of pregnant ladies in every situation of life. Price 1s. All letters (post paid) attended to."

COMMUNICATIONS have been received from:—Dr. J. RICHARD WARDELL; Mr. C. H. MARRIOTT; Dr. BOYCOTT; Dr. BALMAN; Mr. W. C. WALKER; THE HON. SEC. OF THE EPIDEMIOLOGICAL SOCIETY; Dr. J. SPURGIN; Mr. D. KENT JONES; Mr. WILLIAM COPNEY; Dr. C. HOLMAN; Dr. WESTALL; Dr. J. S. WARTER; Dr. W. F. WADE; Mr. FITZGERALD; Dr. MUNROE; A MEDICAL CERTIFICATE; Dr. THORNBURN; Dr. DICK; Mr. J. G. COOK; and Dr. W. ROBERTS.

BOOKS RECEIVED.

1. A Letter to Members of the House of Commons on Poor-Law Medical Relief. By R. Griffin. Weymouth: 1865.
2. Observations on Hay-Fever, Hay-Asthma, or Summer-Catarrh. By W. Abbotts Smith, M.D. London: 1865.
3. Contributions to assist the Study of Ovarian Physiology and Pathology. By C. G. Ritchie, M.D. London: 1865.
4. An Address, or rather an Appeal, to the Governors of the Huddersfield and Upper Abbrigg Infirmary. By T. R. Tatham, M.D. Nottingham: 1865.
5. Strictures on the Administration of Affairs pertaining to the Huddersfield and Upper Abbrigg Infirmary. By T. R. Tatham, M.D. Nottingham: 1865.
